17 Keywords: *Ralstonia eutropha*, lipase, chaperone, triacylglycerol, palm oil, emulsification

18 **ABSTRACT**

1  
2 19 Lipase enzymes catalyze the reversible hydrolysis of triacylglycerol to fatty acids and glycerol  
3  
4 20 at the lipid-water interface. The metabolically versatile *Ralstonia eutropha* strain H16 is  
5  
6 21 capable of utilizing various molecules containing long carbon chains such as plant oil, organic  
7  
8 22 acids, or Tween as its sole carbon source for growth. Global gene expression analysis revealed  
9  
10 23 an upregulation of two putative lipase genes during growth on trioleate. Through analysis of  
11  
12 24 growth and activity using strains with gene deletions and complementations, the extracellular  
13  
14 25 lipase (encoded by the *lipA* gene, locus tag H16\_A1322) and lipase-specific chaperone  
15  
16 26 (encoded by the *lipB* gene, locus tag H16\_A1323) produced by *R. eutropha* H16 was  
17  
18 27 identified. Increase in gene dosage of *lipA* not only resulted in an increase of the extracellular  
19  
20 28 lipase activity, but also reduced the lag phase during growth on palm oil. LipA is a non-  
21  
22 29 specific lipase that can completely hydrolyze triacylglycerol into its corresponding free fatty  
23  
24 30 acids and glycerol. Although LipA is active over a temperature range from 10 to 70°C, it  
25  
26 31 exhibited optimal activity at 50°C. While *R. eutropha* H16 prefers a growth pH of 6.8, its  
27  
28 32 extracellular lipase LipA is most active between pH 7 and 8. Cofactors are not required for  
29  
30 33 lipase activity, however EDTA and EGTA inhibited LipA activity by 83%. Metal ions Mg<sup>2+</sup>,  
31  
32 34 Ca<sup>2+</sup>, and Mn<sup>2+</sup> were found to stimulate LipA activity and relieve chelator inhibition. Certain  
33  
34 35 detergents are found to improve solubility of the lipid substrate or increase lipase-lipid  
35  
36 36 aggregation, as a result SDS and Triton X-100 were able to increase lipase activity by 20 to  
37  
38 37 500%. *R. eutropha* extracellular LipA activity can be hyper-increased, making the  
39  
40 38 overexpression strain a potential candidate for commercial lipase production or in  
41  
42 39 fermentations using plant oils as the sole carbon source.

## 41 INTRODUCTION

42 Lipases (triacylglycerol acylhydrolases) are ubiquitous enzymes in nature. They play  
43 a crucial role in fat metabolism by catalyzing the hydrolysis of triacylglycerol to free fatty  
44 acids and glycerol at the interface of lipid and water (Gupta *et al.*, 2004; Jaeger & Reetz,  
45 1998). Although lipases are highly chemo-, regio-, and chiral- selective enzymes, they also  
46 process esterolytic activities for the carboxyl ester bond cleavage of water-insoluble esters  
47 (Jaeger & Reetz, 1998; Reis *et al.*, 2009; Treichel *et al.*, 2010). Lipases can also catalyze the  
48 reverse reaction in the presence of a low water concentration (Franken *et al.*, 2010; Park *et al.*,  
49 2005; Severac *et al.*, 2011).

50 Lipases are serine hydrolases with a conserved catalytic triad: serine, aspartate or  
51 glutamate, and histidine. These three amino acid residues always appear in this order, but are  
52 distant from each other in the lipase primary sequence. In the lipase tertiary structure, the  
53 catalytic triads are positioned within a close distance to each other in order to catalyze the  
54 hydrolysis reaction (Arpigny & Jaeger, 1999; Gupta *et al.*, 2004; Jaeger & Reetz, 1998; Jaeger  
55 *et al.*, 1999). The mechanism of cleavage involves the deprotonated serine hydroxyl group  
56 nucleophilically attacking the carbonyl carbon of the lipid ester bond. A proton is then  
57 transferred from the triad residues to the substrate hydroxyl group resulting in the cleavage of  
58 the ester bond between the fatty acid and glycerol backbone. The intermediate fatty ester is  
59 then attacked by water to regenerate the catalytic triad and fatty acid (Reis *et al.*, 2009). A  
60 characteristic  $\alpha/\beta$  hydrolase fold was found in all lipase crystallographic structures solved to  
61 date, including bacterial *Pseudomonas* and *Bacillus* lipases, fungal *Rhizomucor* lipases, and  
62 horse and human pancreatic lipases (Arpigny & Jaeger, 1999; Bourne *et al.*, 1994; Derewenda  
63 *et al.*, 1992; Jaeger & Reetz, 1998; Noble *et al.*, 1993; Roussel *et al.*, 1999; Schrag & Cygler,  
64 1997; van Pouderoyen *et al.*, 2001). Since lipase enzymes catalyze reactions at the interface  
65 of water and neutral water-insoluble ester substrates, the catalytic triad that is buried in the  
66 structure must surface in order to access the substrate (Cherukuvada *et al.*, 2005; Reis *et al.*,

67 2009; Wang *et al.*, 2007). This major conformational change results in lipase activity being  
68 highly inducible by lipids, hydrolysable esters, Tween detergents, glycerol, or bile salts  
69 (Boekema *et al.*, 2007; Franken *et al.*, 2010; Gupta *et al.*, 2004; Kim *et al.*, 1996; Lotti *et al.*,  
70 1998; Mahler *et al.*, 2000).

71 Due to the high stability, selectivity, and specificity of lipases, they have been used  
72 extensively in food, detergent, cosmetic, synthesis, and pharmaceutical industries (Jaeger &  
73 Reetz, 1998; Park *et al.*, 2005; Treichel *et al.*, 2010). Bacterial lipases, especially enzymes  
74 from *Bacillus*, *Pseudomonas*, *Burkholderia*, and *Straphylococcus* species, have been  
75 extensively studied and used commercially (Gupta *et al.*, 2004; Jaeger & Eggert, 2002;  
76 Pandey *et al.*, 1999; Rosenstein & Gotz, 2000; Sanchez *et al.*, 2002). These lipases are mostly  
77 extracellular which makes bulk production straightforward. Although many efforts have been  
78 made to increase lipase production in heterologous hosts like *Escherichia coli*, only a few  
79 heterologously-produced lipases are enzymatically active, because lipase gene expression and  
80 secretion are strictly regulated in the host organism (Rosenau & Jaeger, 2000).

81 The metabolically versatile betaproteobacterium *Ralstonia eutropha* strain H16 is able  
82 to grow on various carbon sources including lipids and some detergents (Tween) (Budde *et*  
83 *al.*, 2011a; Riedel *et al.*, 2012; Yang *et al.*, 2010; Budde *et al.*, 2011b; Kahar *et al.*, 2004; Ng  
84 *et al.*, 2010). Since bacteria can only transport free fatty acids into the cytoplasm and utilize  
85 them via the  $\beta$ -oxidation pathway for the generation of the cellular building block acetyl-CoA  
86 and energy, lipids such as triacylglycerol and Tween compounds must be processed first by a  
87 secreted lipase enzyme (Budde *et al.*, 2011a; Budde *et al.*, 2011b; Gupta *et al.*, 2004; Treichel  
88 *et al.*, 2010). Previous microarray analysis by Brigham *et al.* on global gene expression of *R.*  
89 *eutropha* H16 revealed two putative lipase genes (locus tags H16\_A1322 and H16\_A3742)  
90 that were upregulated during trioleate growth. Deletion of lipase H16\_A1322 (GeneID,  
91 4249488) in *R. eutropha* H16 resulted in strain Re2313, which, unlike the wild type strain,  
92 was unable to emulsify palm oil in flask cultures. This suggested that lipase H16\_A1322

93 played a role in the breakdown of triacylglycerol molecules in palm oil, and this breakdown of  
94 oil provided diacylglycerol, monoacylglycerol, and free fatty acids for emulsification of palm  
95 oil remaining in the culture (Brigham *et al.*, 2010). In this study, we have characterized the  
96 *R. eutropha* H16 extracellular lipase (encoded by H16\_A1322; henceforth known as LipA)  
97 and identified its concomitant chaperone (henceforth known as LipB). The properties of this  
98 lipase including relevant physicochemical characteristics and substrate specificities were  
99 examined and reported here.

## 101 MATERIALS AND METHODS

### 102 Bacterial strains and plasmids

103 Experiments were performed with the strains and plasmids listed in Table 1. Mutants  
104 were derived from wild-type *Ralstonia eutropha* H16 (ATCC 17699).

### 105 Growth media and cultivation conditions

106 All *R. eutropha* strains were cultivated aerobically in rich and minimal media with an  
107 initial pH of 6.8 at 30°C. Rich medium consisted of 2.75% (w/v) dextrose-free tryptic soy  
108 broth (TSB) (Becton Dickinson, Sparks, MD). Minimal medium was produced with the  
109 following salts: 4.0 g/L NaH<sub>2</sub>PO<sub>4</sub>, 4.6 g/L Na<sub>2</sub>HPO<sub>4</sub>, 0.45 g/L K<sub>2</sub>SO<sub>4</sub>, 0.39 g/L MgSO<sub>4</sub>, 0.062  
110 g/L CaCl<sub>2</sub>, 0.05% (w/v) NH<sub>4</sub>Cl, and 1 ml/L of a trace metal solution. The trace metal solution  
111 was prepared with 15 g/L FeSO<sub>4</sub>·7H<sub>2</sub>O, 2.4 g/L MnSO<sub>4</sub>·H<sub>2</sub>O, 2.4 g/L ZnSO<sub>4</sub>·7H<sub>2</sub>O, and 0.48  
112 g/L CuSO<sub>4</sub>·5H<sub>2</sub>O in 0.1 M HCl. Carbon sources used were 1% palm oil (Wilderness Family  
113 Naturals, Silver Bay, MN) or 0.5% Tween-60 (Sigma-Aldrich). For all *R. eutropha* cultures,  
114 10 µg/mL final concentration gentamicin was added. Kanamycin at 300 µg/mL concentration  
115 was added to *R. eutropha* with plasmid.

116 A single colony of *R. eutropha* from a TSB agar plate was used to inoculate 5 mL of  
117 TSB medium. The culture was then incubated on a roller drum for 24 h before being used to  
118 inoculate a 100 mL minimal medium flask culture, containing carbon sources mentioned

119 above, to an initial OD<sub>600</sub> of 0.05. The 100 mL minimal medium culture was continuously  
120 shaken in a 30°C incubator at 200 rpm. Aliquots were removed from the flask culture at  
121 intermittent time points for analysis. OD<sub>600</sub> of cultures of each strain were measured  
122 throughout the cultivation period.

### 123 **Plasmid and strain construction**

124 Gene deletions from *R. eutropha* H16 genome were carried out by a standard  
125 procedure described previously (Quandt & Hynes, 1993; York *et al.*, 2001). Standard  
126 molecular biology techniques were performed for all DNA manipulations (Chong, 2001)

127 The plasmid for markerless deletion was constructed by first amplifying approximately  
128 500 base pairs of DNA sequence upstream and downstream of the target deletion gene using  
129 primers with identical sequence overlap at the end (Online Resource 1). Overlap PCR using  
130 these primers resulted in a DNA fragment that contained both the upstream and downstream  
131 region of the target deletion gene. The resulting DNA fragment and parent plasmid, pJV7  
132 (Table 1), were digested with the restriction enzymes XbaI and SacI (New England Biolabs,  
133 Ipswich, MA) and then ligated together to create the gene deletion plasmid. The gene deletion  
134 plasmid was transformed into *Escherichia coli* S17-1 (Simon *et al.*, 1983), which was used as  
135 a donor for the conjugative transfer of mobilizable plasmids. A standard mating-procedure  
136 was performed to introduce the gene deletion plasmid into *R. eutropha* via conjugation (Slater  
137 *et al.*, 1998). Deletion strains were screened via diagnostic PCR with pairs of internal and  
138 external primer sets (Online Resource 1).

### 139 **Lipids extraction and thin layer chromatography analysis**

140 Lipids from palm oil culture supernatants were qualitatively analyzed by thin layer  
141 chromatography (TLC). A 10 mL aliquot of culture was taken at different time points during  
142 the growth of *R. eutropha* H16 and mutant strains on palm oil as the sole carbon source.  
143 Samples were spun down via centrifugation at 4,000 × g, room temperature to separate  
144 supernatant from cell pellets. The lipids in the supernatant were extracted with 5 mL of

145 chloroform/methanol (2:1, v/v) for 1 min with continuous mixing by vortex. The chloroform  
146 layer was removed, allowed to dry, and re-dissolved in fresh chloroform to a final  
147 concentration of 5 mg/mL. Aliquots of 10  $\mu$ L (50  $\mu$ g lipids) were spotted on silica gel TLC  
148 plate (EMD Chemicals, Gibbstown, NJ; 250  $\mu$ m thickness). A mixture with 10  $\mu$ g each of  
149 triacylglycerol (TAG: 1,2-distearoyl-3-oleoyl-rac-glycerol), diacylglycerol (DAG: 1,2-  
150 dipalmitoyl-rac-glycerol), monoacylglycerol (MAG: 1-palmitoyl-rac-glycerol) and free fatty  
151 acid (FFA: palmitate) (Nu-check Prep, Inc., Elysian MN) was also spotted as a standard. The  
152 TLC plate was developed first with chloroform/methanol/water (60:35:5, v/v) to 5 cm above  
153 the origin and then with hexane/diethyl ether/acetic acid (69.5:29.5:1, v/v). To visualize  
154 TAGs and lipase products, a 3% (w/v) cupric acetate solution in 8% (v/v) phosphoric acid was  
155 sprayed lightly and evenly onto the plate. The plate was placed in an oven ( $\sim$ 200 $^{\circ}$ C) for 10 to  
156 30 min to char and then imaged with a camera (Canon, PowerShot Digital SD1200 IS).

### 157 **Lipase Activity assay**

158 Extracellular lipase activity was estimated using a modified protocol from Ng *et al.*  
159 with *p*-nitrophenyl palmitate (*p*NP) as a substrate (Ng *et al.*, 2010). The assay mixture  
160 contains 100 mM glycine-HCl buffer at pH 7.0 and 0.1% (w/v) polyvinyl alcohol. Cell-free  
161 supernatant was added to the assay mixture to a final volume of 900  $\mu$ L and incubated at room  
162 temperature for 5 min. The reaction was initiated by the addition of 0.19 mg *p*NP in 100  $\mu$ L  
163 dimethyl sulphoxide. The absorbance was recorded at OD<sub>405</sub> by a spectrophotometer (Agilent  
164 8453 UV-visible). Control assay mixtures do not contain substrate or cell-free supernatant.  
165 One enzyme unit (U) was defined as one  $\mu$ mol *p*-nitrophenol liberated per min using  
166 extinction coefficient of  $1.78 \times 10^4 \text{ M}^{-1} \text{ cm}^{-1}$ .

### 167 **Effect of pH, temperature, metal ions, and detergents**

168 The effect of pH on lipase activity was tested using 100 mM buffers at various pH  
169 values from 3 to 12. Glycine-HCl buffer was used for the pH range from 3 to 7; pH values

170 from 7.5 to 9 were achieved using Tris buffer; and glycine-NaOH buffer was utilized for pH  
171 values from 9.5 to 12. Cell-free supernatant was incubated with the various pH buffers at  
172 room temperature for 15 min prior to initiation of the reaction with the *p*NP substrate.

173 Temperature effect on lipase activity was assayed using a circulating-bath system  
174 (VWR) coupled to the spectrophotometer. Assay mixture of glycine-HCl (pH 7.0) and  
175 supernatant were incubated at various temperatures from 0 to 80°C for 15 min prior to the  
176 start of the reaction.

177 To test the effect of metals and chelating agents on lipase activity, metal ions (ZnCl<sub>2</sub>,  
178 MgCl<sub>2</sub>, FeCl<sub>2</sub>·4H<sub>2</sub>O, CaCl<sub>2</sub>·2H<sub>2</sub>O, CuCl<sub>2</sub>·2H<sub>2</sub>O, MnCl<sub>2</sub>·4H<sub>2</sub>O, or NiCl<sub>2</sub>·6H<sub>2</sub>O) and chelators  
179 (EDTA, EGTA) at concentrations of 0.1 mM or 1 mM were added to the assay mixture with  
180 glycine-HCl (pH 7.0) buffer and assayed at room temperature. To determine the metal ion  
181 preference for the lipase, 1 mM chelators were first added to the assay mixture and  
182 supernatant to chelate metal ions from the solution. Following chelation, a 1 mM metal ion  
183 solution was added to help restore the activity of the lipase prior to activity assay.

184 To determine the effect of detergents on lipase activity, Tween 20 (polyoxyethylene  
185 (20) sorbitan monolaurate), Tween 40 (polyoxyethylene (20) sorbitan monopalmitate), Tween  
186 60 (polyoxyethylene (20) sorbitan monostearate), Tween 80 (polyoxyethylene (20) sorbitan  
187 monooleate), sodium dodecyl sulfate (SDS), Triton X-100 (tetramethylbutyl phenyl-  
188 polyethylene glycol), or Triton X-305 (octylphenoxypolyethoxyethane) at final  
189 concentrations of 0.001, 0.01, or 0.05% (v/v) was added to the assay mixture with **glycine-**  
190 HCl (pH 7.0). The reaction was carried out at room temperature.

191 All experiments were carried out in triplicates and the values reported are averages of  
192 the three ± standard deviation.

## 194 RESULTS

### 195 Identification of LipA lipase and LipB chaperone pairs

196 Given the lack of evidence that *R. eutropha* H16 can directly uptake palm oil and  
1  
2 197 utilize it for growth, TAGs in palm oil must first be hydrolyzed to free fatty acids (FFAs) by a  
3  
4 198 secreted extracellular lipase and then taken up by the cells. TAG hydrolysis during cultivation  
5  
6  
7 199 of *R. eutropha* H16, Re2313, Re2314, and Re2315 (Table 1) in palm oil cultures were  
8  
9  
10 200 qualitatively analyzed by TLC (Fig. 1). At culture time points of 8, 24, 48, and 72 h, an  
11  
12 201 increase in intensity of the spots corresponding to free fatty acids (FFA), diacylglycerol  
13  
14 202 (DAG), and monoacylglycerol (MAG) with a concomitant decrease in the TAG spot intensity  
15  
16  
17 203 were detected from cultures of wild-type (H16) cells. These observations suggested the  
18  
19 204 presence of an extracellular lipase produced by *R. eutropha* H16 cells for the hydrolysis of the  
20  
21  
22 205 TAGs in palm oil into DAGs, MAGs, and FFAs during growth. Strain Re2313, a  $\Delta lipA$   
23  
24 206 derivative of H16, was unable to hydrolyze TAGs to the extent of wild-type cells, which  
25  
26  
27 207 resulted in unchanged TAG spot intensities on the TLC plate over the entire cultivation time.  
28  
29 208 The same phenotype was observed for the mutant strain Re2315 with a deletion of both *lipA*  
30  
31  
32 209 and H16\_A3742 (annotated as a putative lipase) genes. However a single deletion of the  
33  
34 210 H16\_A3742 gene (strain Re2314) had no defect in TAG cleavage and resulted in a similar  
35  
36  
37 211 phenotype as compared to the wild type. This suggested that only the *lipA* gene is responsible  
38  
39 212 for the production of the extracellular lipase that is able to hydrolyze TAGs in palm oil and  
40  
41 213 liberate FFAs for cellular usage in *R. eutropha* H16 cultures.

44 214 Introduction of the *lipA* gene into the mutant strain Re2313 via the overexpression  
45  
46 215 plasmid pCJB201 was able to restore the TAG cleavage function of this strain (Fig. 2).  
47  
48  
49 216 Increasing the *lipA* gene dosage in both wild type and Re2313 resulted in more rapid TAG  
50  
51 217 hydrolysis compared to just the wild type cell with vector alone (pBBR1MCS-2). The TAG  
52  
53  
54 218 spot intensity on the TLC plate decreased dramatically over the first 24 h and completely  
55  
56 219 disappeared by 48 h when *lipA* was overexpressed. FFAs derived from TAGs built up in the  
57  
58  
59 220 media throughout cultivation time in the overexpression strains. This is likely the result of

221 rapid FFA production outpacing FFA uptake and incorporation into the cell or accumulation  
1  
2 222 of excess FFAs not needed for cell growth.  
3

4 223 Expression of *lipA* in heterologous hosts, such as *E. coli* and yeast, failed to produce  
5  
6  
7 224 an active lipase, which led us to the characterization of a lipase-specific foldase gene, *lipB*  
8  
9 225 (H16\_A1323), that is just downstream of *lipA*. Deletion of *lipB* (strain Re2318) showed the  
10  
11 226 same growth phenotype in palm oil cultures as Re2313 (Online Resource 2). Introduction of  
12  
13 227 the plasmid-borne *lipA* gene to Re2318 did not restore TAG hydrolysis (data not shown),  
14  
15 228 suggesting that LipA is a Class I lipase that requires its specific chaperone (i.e. LipB) for  
16  
17 229 folding and secretion (Arpigny & Jaeger, 1999; Frenken *et al.*, 1993a; Frenken *et al.*, 1993b;  
18  
19 230 Hobson *et al.*, 1993). LipA from *R. eutropha* H16 shares 48% and 44% sequence identity to  
20  
21 231 the *Ralstonia* sp. M1 and *Pseudomonas* sp. lipases, respectively, while the chaperone LipB  
22  
23 232 only had 45% and 27% sequence identity to chaperones of the same class (Gilbert, 1993; Kim  
24  
25 233 *et al.*, 2001; Quyen *et al.*, 2004; Quyen *et al.*, 2005).  
26  
27  
28  
29  
30

31 234 Further analysis of the secreted protein in supernatants of *R. eutropha* H16,  
32  
33 235 H16/pCJB201 (*lipA* overexpression), Re2313 ( $\Delta lipA$ ), and Re2318 ( $\Delta lipB$ ) were grown in  
34  
35 236 cultures containing palm oil. After 24 h, culture supernatants were harvested and subjected to  
36  
37 237 SDS-PAGE analysis. The presence of a ~40 kDa protein on the gel was observed, but only for  
38  
39 238 strains containing intact *lipA* and/or *lipB* genes (Online Resource 3). The LipA enzyme  
40  
41 239 H16\_A1322 has a molecular weight of 38.6 kDa based on its primary amino acid sequence.  
42  
43 240 H16/pCJB201 overexpressing *lipA* exhibited an increase in the amount of protein at ~40  
44  
45 241 kDa as compared to wild type. This observation suggests that LipA and LipB work together  
46  
47 242 as an extracellular lipase/chaperone pair.  
48  
49

### 51 243 **Growth and Lipase activity**

52  
53 244 Strains H16, Re2313, and Re2318 were individually cultivated in minimal media  
54  
55 245 containing 1% palm oil as the sole carbon source (Fig. 3A). Wild type H16 with an intact  
56  
57 246 *lipA* gene reached an OD<sub>600</sub> of 15.0 by 48h. Strain Re2313 lacks *lipA* for the production of  
58  
59  
60  
61  
62  
63  
64  
65

247 extracellular lipase, and not only was unable to hydrolyze TAGs in palm oil, but also did not  
1  
2 248 grow significantly in the presence of unemulsified palm oil (Fig. 1). Strain Re2318, which  
3  
4 249 lacks lipase chaperone LipB, also was unable to grow on palm oil.  
5  
6

7 250 Activity of LipA was determined in the cell supernatants during palm oil cultivation of  
8  
9 251 wild type, Re2313, and Re2318 strains (Fig. 3B). Both Re2313 and Re2318 lack the gene for  
10  
11 252 the production or secretion of active lipase, respectively, thus no lipase activity was detected  
12  
13 253 (Fig. 3B). In strain H16, lipase activity was determined to be ~47 mU/mL after 5 h of culture  
14  
15 254 and remained active till after 24 h (Fig. 3B). Reintroduction *in trans* of the *lipA* gene  
16  
17 255 or the *lipB* gene into strains Re2313 or Re2318, respectively, restored growth of these strains  
18  
19 256 on palm oil and also their lipase activities (Fig. 4). Re2313/pCJB201 exhibited four times  
20  
21 257 higher lipase activity than the wild-type strain, due to the increase of lipase gene dosage (Fig.  
22  
23 258 4B). Strains Re2313/pCJB201 and H16/pCJB201 exhibit a decreased lag in growth in palm  
24  
25 259 oil cultures as compared to the wild type, due to the increase in lipase activity (Fig. 4A).  
26  
27 260 Although the chaperone gene was overexpressed in the same way as the lipase gene in  
28  
29 261 Re2318/pJL36, the growth rate and lipase activity was found to be similar to the wild-type  
30  
31 262 strain (Fig. 4). Reintroduction of the chaperone gene was able to restore the secretion  
32  
33 263 mechanism of the lipase, but did not result in higher than wild-type levels of lipase activity.  
34  
35 264 Lipase activity reached 1 U/mL when *lipA* was overexpressed in strain H16, thus explaining  
36  
37 265 the rapid TAGs cleavage, compared to H16 with vector alone, as also detected by TLC (Fig.  
38  
39 266 2).  
40  
41

42  
43 267 LipA production by *R. eutropha* was induced by growth on various carbon sources  
44  
45 268 (Table 2). Initial extracellular lipase activity was detected at 3 h after inoculation (data not  
46  
47 269 shown). Lipase activity was dependant on the carbon source used; the activity at 10 h varied  
48  
49 270 from 0.5 mU/mL in Tween 20 to 200 mU/mL in Tween 60. LipA was also produced and  
50  
51 271 active with non-lipid carbon sources such as fructose. Of the carbon sources tested in this  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

272 study, the LipA activity was observed in the following order (from highest to lowest  
1  
2 273 activities): Tween 60> Tween 80>Palm Oil>Tween 40>Fructose> Tween 20 (Table 2).

### 274 **Decreased lag phase due to lipase overexpression**

275 Growth of strain H16/pCJB201 in palm oil cultures not only resulted in quick TAG  
8  
9 276 cleavage (Fig. 2), but also shortened the lag phase of growth (Fig. 4A, 5). Wild-type culture  
10  
11 277 experienced a ~22 h lag phase when grown on palm oil as the sole carbon source.  
12  
13 278 H16/pCJ201, on the other hand, reached exponential growth phase in less than 12 h. The  
14  
15 279 increased amount of DAGs, MAGs, and FFAs liberated from TAG hydrolysis in the growth  
16  
17 280 media acted as a natural surfactant and enhanced the oil emulsification during growth on palm  
18  
19 281 oil (Online Resource 4). Thus, the amount of time needed for the cells to adapt to the two-  
20  
21  
22 282 phase heterogeneity of the palm oil growth medium decreased significantly.

### 283 **Substrate specificity**

284 Substrate specificities of lipase enzymes classify them into one of the following  
28  
29 285 categories: non-specific, regio-specific, or fatty acid-specific. Non-specific hydrolysis will  
30  
31 286 result in complete breakdown of the TAG molecule into FFAs and glycerol, while regio-  
32  
33 287 specific lipase will catalyze hydrolysis only at C1 and C3 position of the glycerol backbone.  
34  
35  
36 288 Fatty acid-specific lipase will only cleave fatty acid esters of certain chain lengths such as C12  
37  
38  
39 289 lipids or C16 lipids (Arpigny & Jaeger, 1999; Gupta *et al.*, 2004; Treichel *et al.*, 2010). The  
40  
41 290 TLC analysis of H16/pCJB201 resulted in complete hydrolysis of TAGs, DAGs, and MAGs  
42  
43 291 in the media into FFAs (Fig. 2), suggesting that LipA is a non-specific lipase able to act at  
44  
45  
46 292 random for the complete breakdown of TAGs.

### 51 293 **Effect of temperature, pH, metal ions, and detergents**

52  
53 294 The effects of temperature, pH, metal ions, and detergents on lipase activity were  
54  
55 295 studied using culture supernatants of *R. eutropha* grown in Tween 60 for 10 h, since Tween  
56  
57  
58 296 60 as the carbon source showed the highest induction of LipA activity compared to other  
59  
60 297 carbon sources tested (Table 2). Lipase activity was measured at various temperatures from 0  
61  
62  
63  
64  
65

298 to 80°C. LipA was active from 10 to 70°C (Fig. 6A). The optimal activity was observed at a  
299 temperature of 50°C, in which the activity reached 27 U/mL at pH 7. Although *R. eutropha*  
300 prefers 30°C for growth, its extracellular lipase is quite thermostable and remained active  
301 even at high temperatures.

302 Buffers of pH 3 to 12 were used to determine the pH optimum for LipA activity. The  
303 pH for best growth and lipase production was shown to be pH 6.8 for *R. eutropha*. LipA  
304 showed maximum activity at pH 7.0 to 8.0, when the activity reached 3 U/mL at room  
305 temperature (Fig. 6B). LipA was active in buffers ranging from pH 5 to pH 10 with a slight  
306 preference towards the alkaline pH buffers.

307 Although a metal cofactor is typically not involved in the mechanism of catalysis of  
308 lipases, divalent cations were reported to stimulate or inhibit lipase activity (El Khattabi *et al.*,  
309 2003; Gupta *et al.*, 2004; Rosenstein & Gotz, 2000). Divalent metal ions  $Zn^{2+}$ ,  $Mg^{2+}$ ,  $Fe^{2+}$ ,  
310  $Ca^{2+}$ ,  $Cu^{2+}$ ,  $Mn^{2+}$ , and  $Ni^{2+}$ , along with their chelators (EDTA and EGTA), were added at  
311 different concentrations to the assay mixture to examine their effect on LipA activity (Table  
312 3). At concentrations of 0.1 mM, transition metal chelator EDTA and  $Ca^{2+}$ -chelator EGTA  
313 imparted little inhibition on LipA activity. At the same concentration,  $Zn^{2+}$  and  $Cu^{2+}$  inhibited  
314 LipA activity by ~50% while all other metal ions had little to no effect. The activity of LipA  
315 decreased dramatically to 3 - 18% of total activity when 1 mM of either chelators,  $Zn^{2+}$ ,  $Fe^{2+}$ ,  
316  $Cu^{2+}$ , or  $Ni^{2+}$  were added. A 1 mM concentration of  $Mg^{2+}$  only inhibited LipA by 28%, while  
317  $Ca^{2+}$  and  $Mn^{2+}$  ions had no effect at all on lipase activity. This suggested that LipA activity  
318 could be inhibited by  $Zn^{2+}$ ,  $Fe^{2+}$ ,  $Cu^{2+}$ , or  $Ni^{2+}$  but only slightly inhibited by  $Mg^{2+}$ , while  
319 activity was not affected by  $Ca^{2+}$ , and  $Mn^{2+}$  ions.

320 To test if  $Mg^{2+}$ ,  $Ca^{2+}$ , and  $Mn^{2+}$  can reverse the inhibition caused by chelators, 1 mM  
321 of each ion was added separately to assay mixtures after the addition of 1 mM of both  
322 chelators (Fig. 7). While chelators EDTA and EGTA inhibited the LipA activity by 83%,  
323 addition of  $Mg^{2+}$ ,  $Ca^{2+}$ , or  $Mn^{2+}$  alleviated this inhibition and helped restore the LipA activity

324 back to 80 to 95% of its original levels. Other metals had no effect on the inhibition caused  
1  
2 325 by the addition of chelators. These results demonstrate that  $Mg^{2+}$ ,  $Ca^{2+}$ , and  $Mn^{2+}$  divalent  
3  
4 326 metal ions can stimulate lipase activity and alleviate chelator caused inhibition.  
5  
6

7 327 Detergents are known to either increase solubility of lipids (i.e. act as emulsifiers) or  
8  
9 328 induce lipid aggregation, thus allowing lipase to better access the lipid substrate (Lin *et al.*,  
10  
11 329 1995; Reis *et al.*, 2009). To test the effect of detergents on LipA activity, 0.001, 0.01, and  
12  
13 330 0.1% (v/v) of Tween 20, Tween 40, Tween 60, or Tween 80, Triton X-100 or Triton 305, or  
14  
15 331 SDS detergents was added to the enzymatic assay mixture at room temperature and pH 7.0  
16  
17 332 (Table 4). At low concentrations (0.001% v/v), Tween 40, Tween 60, Tween 80, and SDS all  
18  
19 333 inhibited LipA activity by ~90%. However, an increase in the concentration to 0.01% (v/v) of  
20  
21 334 Tween 40, Tween 60, Tween 80, and SDS helped restore the lipase activity. Interestingly  
22  
23 335 Tween 40, which had restored LipA activity at 0.01% then again inhibited the activity at  
24  
25 336 0.1%. Addition of increasing concentration of Tween 20 resulted in LipA activity decrease by  
26  
27 337 <90%. Triton X-100 was able to **increase** LipA activity by 586% at 0.001% and 333% at  
28  
29 338 0.1%. Increasing concentration of Triton X-305 reduced LipA activity by ~70%; however at  
30  
31 339 0.1% the LipA activity was restored to normal. This suggested that although some detergents  
32  
33 340 could help stimulate LipA activity, the mechanism of detergent concentration to LipA activity  
34  
35 341 is complex.  
36

44 342

## 45 343 **DISCUSSION**

46 344 In this study, we have characterized the extracellular triacylglycerol hydrolase from *R.*  
47  
48 345 *eutropha* H16. This lipase, LipA, contains the conserved lipase catalytic triad Ser, His, and  
49  
50 346 Asp in its primary structure (**Online Resource 5**). Since LipA requires a lipase-specific  
51  
52 347 foldase, **LipB**, to achieve its correct catalytic tertiary structure and be secreted outside of the  
53  
54 348 cell, it belongs to the Class I lipase family (Arpigny & Jaeger, 1999; Frenken *et al.*, 1993b;  
55  
56 349 Hobson *et al.*, 1993). Protein sequence homology revealed that LipA and **LipB**, the lipase and  
57  
58  
59  
60  
61  
62  
63  
64  
65

350 chaperone pair of *R. eutropha* H16 were similar to those from *Ralstonia* sp. M1 (Quyen *et al.*,  
1  
2 351 2004; Quyen *et al.*, 2005). LipA primary sequence contains three cysteine residues ([Online](#)  
3  
4 352 [Resource 5](#)) with the possibility of disulfide bond formation, and chaperone [LipB](#) could be  
5  
6  
7 353 required for this reduction *in vivo* (Kok *et al.*, 1996).  
8

9 354 LipA from *R. eutropha* H16 was determined to be a non-specific lipase, because it was  
10  
11 355 able to completely hydrolyze TAGs into FFAs and glycerol. Non-specific lipases hold great  
12  
13  
14 356 importance in the field of biodiesel fuel production from TAGs, since they can act at random  
15  
16  
17 357 and fully breakdown TAGs (Bajaj *et al.*, 2010; Fjerbaek *et al.*, 2009; Jegannathan *et al.*, 2010;  
18  
19 358 Singh & Singh, 2010). Also, since LipA is a secreted lipase, its isolation process would be  
20  
21  
22 359 simplified, compared to intracellular lipases from other species, for lipase immobilization  
23  
24 360 applications (Fjerbaek *et al.*, 2009; Gupta *et al.*, 2004; Jaeger & Reetz, 1998). LipA can also  
25  
26 361 catalyze a diverse range of substrates such as Tween 20, Tween 40, Tween 60, and Tween 80,  
27  
28  
29 362 due to its broad range of selectivity. The reaction rate of such catalysis varies directly and  
30  
31  
32 363 extensively with the chemical properties of the substrate. LipA favored Tween 60 as a  
33  
34 364 substrate compared to other Tween compounds, with the least favored being Tween 20. LipA  
35  
36 365 could favor long chain length linear fatty esters, since the hydrolysis of Tween 60 can only  
37  
38  
39 366 liberate stearic acid (18 carbon linear chain).  
40

41 367 Overexpression of the *lipA* gene on a plasmid not only increased the TAG hydrolysis  
42  
43 368 rate in culture but also resulted in a shortened *R. eutropha* lag phase when grow on palm oil.  
44  
45  
46 369 Biotechnological usage of LipA would reduce the dependence on surfactants, since more  
47  
48  
49 370 DAGs, MAGs, and FFAs, that act as natural surfactants, can be liberated from the rapid  
50  
51 371 hydrolysis of TAGs in the initial growth stage (Jaeger & Eggert, 2002; Skagerlind *et al.*,  
52  
53 372 1992). The industrial fermentation time could be shortened, using a strain of *R. eutropha* that  
54  
55  
56 373 overexpresses *lipA*, because the cells can reach the stationary phase in half of the normal  
57  
58 374 growth time, due to the increased amount of FFAs present in the culture for cell growth and  
59  
60  
61 375 biosyntheses.  
62  
63  
64  
65

376 Lipase activity can be affected not only by the carbon sources used, but also by  
1  
2 377 physico-chemical factors such as temperature, pH, metal ion, and detergent. Although the  
3  
4 378 optimal temperature and pH for lipase production correspond with the growth temperature and  
5  
6  
7 379 pH of the host microorganisms, most secreted lipases are active in a wide range of  
8  
9  
10 380 temperatures and pHs (Gupta *et al.*, 2004). *R. eutropha* H16 LipA showed high activity at  
11  
12 381 50°C, which is similar to many other characterized bacterial lipases (Gupta *et al.*, 2004).  
13  
14 382 Most of the previously studied lipases have temperature optima in the range of 30 to 60°C,  
15  
16  
17 383 although some extreme lipases were also found that exhibited high activity even at low or  
18  
19  
20 384 high temperatures (Jeon *et al.*, 2009; Joseph *et al.*, 2008; Kulkarni & Gadre, 1999; Nawani &  
21  
22 385 Kaur, 2007). Adjustment of the temperatures for optimal lipase performance, depending on  
23  
24 386 application, can be achieved through the use of stabilizers such as ethylene glycol, sorbitol, or  
25  
26  
27 387 glycerol (Franken *et al.*, 2010; Gupta *et al.*, 2004). LipA had neutral to slightly alkaline pH  
28  
29 388 optimum that is similar to most known bacterial lipases (Gupta *et al.*, 2004; Kanwar *et al.*,  
30  
31  
32 389 2002; Lesuisse *et al.*, 1993).

34 390 TAG hydrolysis by lipase does not require specific cofactors, although Ca<sup>2+</sup> has been  
35  
36 391 reported to stimulate the activity of lipases from *Bacillus*, *Pseudomonas*, *Chromobacterium*,  
37  
38  
39 392 and *Acinetobacter* species (Gupta *et al.*, 2004; Kanwar *et al.*, 2002; Rathi *et al.*, 2001). The  
40  
41 393 function of Ca<sup>2+</sup> in lipase is highly debatable. It has been hypothesized that the released fatty  
42  
43  
44 394 acids associate with Ca<sup>2+</sup> to form calcium salts, and thus relieve product (FFA) inhibition  
45  
46 395 (Godtfredsen, 1990; Macrae & Hammond, 1985). Also, the role of Ca<sup>2+</sup> was thought to  
47  
48  
49 396 stabilize the lipase tertiary structure. It has also been theorized that there is a direct  
50  
51 397 involvement of Ca<sup>2+</sup> in the catalysis for the activation of water molecules; however, this  
52  
53  
54 398 theory is highly unlikely since the calcium-binding site was found to be far from the active  
55  
56 399 site in the *Burkholderia glumae* lipase crystal structure (Jaeger *et al.*, 1999; Noble *et al.*, 1993;  
57  
58 400 Rosenstein & Gotz, 2000; Verheij *et al.*, 1980); (Simons *et al.*, 1999). The metal chelators  
59  
60  
61 401 EDTA and EGTA acted as inhibitors to all lipases, including LipA. Although the role of Ca<sup>2+</sup>

402 was not elucidated, it alleviated inhibition by chelation and stimulated LipA activity. Calcium  
1  
2 403 ion could also be replaced by Mg<sup>2+</sup> or Mn<sup>2+</sup> without loss of activity in LipA. Reported in the  
3  
4 404 literature, divalent cations Sr<sup>2+</sup> or Ba<sup>2+</sup> can also replace Ca<sup>2+</sup> in lipase (Gupta *et al.*, 2004).  
5  
6  
7 405 The LipA primary sequence contains several aspartate residues that could be responsible for  
8  
9 406 the binding of calcium (Online Resource 5). To test the residues involved in potential Ca<sup>2+</sup>  
10  
11  
12 407 binding, site-directed mutagenesis could be employed. Furthermore, like many reported  
13  
14 408 lipases, LipA activity was inhibited by metal chelators (Table 3, Fig. 7) and by various heavy  
15  
16  
17 409 metals (Gupta *et al.*, 2004).

19 410 Lipase activity is highly inducible and the activity is dependent on substrate  
20  
21  
22 411 concentrations at the interface of water and lipid. Detergents, at a specific concentration, can  
23  
24 412 cause non-polar substrates to aggregate or solubilize in water thus dramatically increasing the  
25  
26 413 activity of lipase (Boekema *et al.*, 2007; Reis *et al.*, 2009). The addition of small amounts of  
27  
28  
29 414 Triton X-100 could cause a shift in the solubility equilibrium and cause substrate aggregation  
30  
31  
32 415 because the substrate concentration exceeded the solubility limit. Such change at the interface  
33  
34 416 strongly activated LipA activity. Detergents such as Tween 20 could compete with the LipA  
35  
36 417 active site, thus inhibiting the activity of LipA in our assay system. Thus, dependant on the  
37  
38  
39 418 type and concentration of detergents, LipA activity was either enhanced or inhibited. LipA  
40  
41 419 characterized here had similar activity response to detergents as LipA from *Ralsonia* sp. M1  
42  
43 420 (Quyen *et al.*, 2005). Since much is still unknown regarding lipase catalysis at the water-oil  
44  
45  
46 421 interface, the use of detergent-based inducers can only be determined experimentally at this  
47  
48  
49 422 time.

51 423 It has long been established that *R. eutropha* is the model organism for the production  
52  
53 424 of polyhydroxyalkanoate (PHA), a polyester that can potentially replace current petroleum-  
54  
55  
56 425 based plastics in many applications. Palm oil is a promising carbon source because it is a  
57  
58 426 readily available agricultural byproduct and has high density carbon content. Recently Riedel  
59  
60  
61 427 *et al.* were able to produce over 139 g/L of biomass using engineered *R. eutropha* with 74%

428 of cell dry weight as PHA, using palm oil as the sole carbon source (Riedel *et al.*, 2012). *R.*  
1  
2 429 *eutropha* growth in palm oil, or any plant oil, presents challenges due to the heterogeneity  
3  
4  
5 430 between the oil feedstock and the aqueous media. Emulsifiers, such as the glycoprotein gum  
6  
7 431 Arabic, were able to emulsify the palm oil in growth medium and make it more bioavailable  
8  
9  
10 432 without influencing *R. eutropha* growth (Budde *et al.*, 2011a). In this work, overexpression  
11  
12 433 of extracellular LipA in *R. eutropha* allowed for rapid TAGs hydrolysis (Fig. 2) with liberated  
13  
14 434 DAGs, MAGs, and FFAs acting as natural surfactants and ultimately resulted in a faster  
15  
16  
17 435 growth rate (Fig. 4A, 5). Such properties could potentially make LipA an enzyme with  
18  
19 436 important biotechnological usage, especially in the production of PHA from palm oil.

## 23 24 438 **ACKNOWLEDGEMENTS**

25  
26 439 The authors thank Dr. Charles F. Budde for his helpful ideas and discussions; Mr. John W.  
27  
28  
29 440 Quimby and Sebastian Riedel, Dipl.-Ing. (FH) for critical review of the manuscript. This  
30  
31 441 work was funded by the Malaysia-MIT Biotechnology Partnership Program (MMBPP). We  
32  
33  
34 442 thank our MMBPP collaborators for their helpful discussions and support throughout the  
35  
36 443 course of this study.

## TABLES

Table 1

Strains and plasmids used in this work.

Strains or plasmid	Genotype	Reference
Strains		
<i>R. eutropha</i>		
H16	Wild-type, gentamicin resistant (Gen <sup>r</sup> )	ATCC17699
Re2313	H16 $\Delta$ <i>lipA</i> Gen <sup>r</sup>	(Brigham <i>et al.</i> , 2010)
Re2314	H16 $\Delta$ (H16_A3742) Gen <sup>r</sup>	This work
Re2315	H16 $\Delta$ <i>lipA</i> & A3742 Gen <sup>r</sup>	This work
Re2318	<b>H16<math>\Delta</math><i>lipB</i></b> Gen <sup>r</sup>	This work
<i>E. coli</i>		
S17-1	Conjugation strain for transfer of plasmids into <i>R. eutropha</i>	(Simon <i>et al.</i> , 1983)
Plasmids		
pJV7	pJQ200Kan with $\Delta$ <i>phaC1</i> allele inserted into BamHI restriction site, confers kanamycin resistance (Kan <sup>r</sup> )	(Budde <i>et al.</i> , 2011a)
pJL31	pJV7 with $\Delta$ <i>phaC1</i> allele removed by XbaI and SacI digestion and replace with $\Delta$ <i>lipB</i> allele (Kan <sup>r</sup> )	This work
pBBR1MCS-2	Broad-host-range cloning vector (Kan <sup>r</sup> )	(Simon <i>et al.</i> , 1983)
pCJB201	pBBR1MCS-2 with <i>R. eutropha lipA</i> gene inserted into the multiple cloning site (Kan <sup>r</sup> )	(Brigham <i>et al.</i> , 2010)
pJL36	pBBR1MCS-2 with <i>R. eutropha lipB</i> gene inserted into the multiple cloning site (Kan <sup>r</sup> )	This work

**Table 2**Effect of carbon sources on lipase production<sup>a</sup>.

Carbon source	Lipase activity (mU/mL)
Fructose (0.5% w/v)	4.6±0.3
Palm Oil (0.5% v/v)	38.0±0.8
Tween 20 (0.5% v/v)	0.5±0.1
Tween 40 (0.5% v/v)	36.0±1.0
Tween 60 (0.5% v/v)	200.0±20.0
Tween 80 (0.5% v/v)	91.0±5.0

<sup>a</sup>Each value represents the mean ± standard error on n = 3. Supernatants of *R. eutropha* strain H16 grown in various carbon sources were collected at 10 h of culture time for activity assays. Lipase activity was determined at room temperature, pH 7.0 in glycine-HCl buffer.

**Table 3**Effect of various metal ions or chelating agents on lipase activity<sup>a</sup>.

Metal ion	Relative activity (%) (0.1 mM metal ion or chelator)	Relative activity (%) (1 mM metal ion or chelator)
None	100	100
EDTA & EGTA	91	15
ZnCl <sub>2</sub>	43	3
MgCl <sub>2</sub>	94	72
FeCl <sub>2</sub>	86	18
CaCl <sub>2</sub>	98	99
CuCl <sub>2</sub>	68	11
MnCl <sub>2</sub>	115	99
NiCl <sub>2</sub>	90	7

<sup>a</sup>Enzymatic assay was carried out at room temperature with pH 7.0 glycine-HCl buffer.

**Table 4**Effect of detergents on lipase activity<sup>a</sup>.

Detergent	Relative activity (%) (0.001% v/v detergent)	Relative activity (%) (0.01% v/v detergent)	Relative activity (%) (0.1% v/v detergent)
None	100	100	100
Tween 20	120	66	2
Tween 40	5	117	8
Tween 60	7	10	27
Tween 80	5	9	83
Triton X-100	686	543	433
Triton X-305	77	27	112
SDS	11	38	126

<sup>a</sup>Lipase assay was conducted with pH7.0 glycine-HCl buffer at room temperature.
