INTRODUCTION

This report completes the hydrographic data series obtained during 27 monthly oceanographic cruises in Monterey Bay. This oceanographic study was initiated under a grant from the Office of Sea Grant Programs, and the data collection began in February 1971. In September 1971 additional funding was received from the Association of Monterey Bay Area Governments. The data obtained during 1971 have been published previously (Broenkow 1972), and some initial interpretation of this work has been reported by Smethie (1973), Broenkow and Smethie (1973), and Oceanographic Services, Inc. (1973).

## METHODS

Station Position. When the shoreline was clearly visible, station positions were determined using horizontal sextant angles with an accuracy of about  $\pm$  0.1 mile within 1 mile of shore and  $\pm$  0.3 mile within 6 miles of shore. During inclement weather a combination of loran, radar ranges and bearings and fathometer readings were used, and in most cases the accuracy of the position was about  $\pm$  0.5 mile or better.

Hydrographic Sampling. Four 5-liter Niskin plastic sampling bottles were used to obtain discrete water samples at the standard sampling depths, 0, (5), 10, 20, 30, 50, 75, 100, 150, 200, 250, 300, and 400 m. Accepted sampling depths were determined from wire angle for depths less than 100 m and from a combination of wire angle and thermometric depth calculations for depths greater than 100 m.

Temperature. The in situ temperature was determined from paired reversing thermometers. The average temperature is recorded when the thermometers agreed to within 0.05° C.

Salinity. Salinity was determined using a Kahlisco precision induction salinometer. Analyses were made in the laboratory and salinity was computed from conductivity ratio using the equations of Cox, et al (1967). Substandard seawater was used to calibrate the salinometer before and after each set of 24 or fewer samples. Copenhagen water was used each month to standardize the substandard water.

Dissolved Oxygen. Water samples were treated aboard ship to fix the oxygen in the basic form. The samples were acidified and titrated in the laboratory within 12 hours of the sampling time using Carpenter's (1965) modification of the Winkler method. The total sample is titrated with approximately 0.02 N sodium thiosulfate to the starch endpoint. Precision of the analyses is about  $\pm$  0.06 ml/liter (2 SD).

Nutrient Ions. The 500 ml samples were filtered through 3  $\mu\text{m}$  glass fiber filters, quick frozen in a dry ice-alcohol solution aboard ship and were refrigerated at -10° C until analyzed ashore within 3 weeks of collection. Groups of 36 samples were quick-thawed in the laboratory just prior to the analyses for phosphate, nitrate, nitrite ammonia, and silica. Standards and reagent blanks were prepared fresh daily and were determined with each set of samples.

. Dissolved reactive phosphate was determined by the method of Murphy and Riley (1962) described in Strickland and Parsons (1968) using ascorbic acid to reduce the phospho-molybdate complex. The sample absorbance was determined in 10 cm cells on a Beckman DU II Spectrophotometer at 885 nm. Precision of the analyses is about  $\pm$  0.03  $\mu\text{g}\text{-atoms/liter}$  (2 SD).

Nitrate was determined by the cadmium-reduction method of Wood et al (1967) followed by the nitrite color development. The sample absorbance was determined in 1 cm cells

using a Spectronic 20 Colorimeter at 543 nm. Precision of the analyses is about  $\pm$  0.5  $\mu\text{g-atoms/liter}$  (2 SD).

Nitrite was determined by the method of Bendschneider and Robinson (1952) described by Strickland and Parsons (1967). The absorbance of the diazo color was determined on the Beckman DU using 10 cm cells at 543 nm. Precision of the method is about  $\pm$  0.03  $\mu\text{g-atoms/liter}$  (2 SD).

Ammonia was determined by the indophenol method of Solorzano (1969) with the color absorbance determined with the Beckman DU at 640 nm using 10 cm cells. Precision of the method is about  $\pm$  0.1  $\mu\text{g-atoms/liter}$  (2 SD).

Reactive silica was determined by the method of Mullin and Riley (1955) as modified by Strickland and Parsons (1968). The silicomolybdate complex was reduced by a metol-sulfite, oxalic acid solution, and the color absorbance was determined in 1 cm cells on a Spectronic 20 at 810 nm. Precision of the method is about  $\pm$   $\mu\text{g-atoms/liter}$  (2 SD).
