## **NOAA TECHNICAL REPORTS NMFS**

The major responsibilities of the National Marine Fisheries Service (NMFS) are to monitor and assess the abundance and geographic distribution of fishery resources, to understand and predict fluctuations in the quantity and distribution of these resources, and to establish levels for optimum use of the resources. NMFS is also charged with the development and implementation of policies for managing national fishing grounds, development and enforcement of domestic fisheries regulations, surveillance of foreign fishing off United States coastal waters, and the development and enforcement of international fishery agreements and policies. NMFS also assists the fishing industry through marketing service and economic analysis programs, and mortgage insurance and vessel construction subsidies. It collects, analyzes, and publishes statistics on various phases of the industry.

The NOAA Technical Report NMFS series was established in 1983 to replace two subcategories of the Technical Reports series: "Special Scientific Report—Fisheries" and "Circular." The series contains the following types of reports: Scientific investigations that document long-term continuing programs of NMFS, intensive scientific reports on studies of restricted scope, papers on applied fishery problems, technical reports of general interest intended to aid conservation and management, reports that review in considerable detail and at a high technical level certain broad areas of research, and technical papers originating in economics studies and from management investigations.

Copies of NOAA Technical Report NMFS are available free in limited numbers to governmental agencies, both Federal and State. They are also available in exchange for other scientific and technical publications in the marine sciences. Individual copies may be obtained from: Publications Services Branch (E/AI 13), National Environmental Satellite, Data, and Information Service, National Oceanic and Atmospheric Administration, U.S. Department of Commerce, 3300 Whitehaven St., Washington, DC 20235.

# Net Phytoplankton and Zooplankton in the New York Bight, January 1976 to February 1978, With Comments on the Effects of Wind, Gulf Stream Eddies, and Slope Water Intrusions

DANIEL E. SMITH and JACK W. JOSSI<sup>1</sup>

## ABSTRACT

Results are given of monthly net phytoplankton and zooplankton sampling from a 10 m depth in shelf, slope, and Gulf Stream eddy water along a transect running southeastward from Ambrose Light, New York, in 1976, 1977, and early 1978. Plankton abundance and temperature at 10 m and sea surface salinity at each station are listed. The effects of atmospheric forcing and Gulf Stream eddies on plankton distribution and abundance are discussed. The frequency of Gulf Stream eddy passage through the New York Bight corresponded with the frequency of tropical-subtropical net phytoplankton in the samples. Gulf Stream eddies injected tropical-subtropical zooplankton onto the shelf and removed shelfwater and its entrained zooplankton. Wind-induced offshore Ekman transport corresponded generally with the unusual timing of two net phytoplankton maxima. Midsummer net phytoplankton maxima were recorded following the passage of Hurricane Belle (August 1976) and a cold front (July 1977). Tropical-subtropical zooplankton which had been injected onto the outer shelf by Gulf Stream eddies were moved to the inner shelf by a wind-induced current moving up the Hudson Shelf Valley.

## INTRODUCTION

The New York Bight contains abundant living marine resources. It is used extensively for urban waste disposal, merchant shipping, recreation, coastal zone construction, and fishing (Gross et al. 1976).

Concern over the possibility of these uses affecting the natural resources of the New York Bight has aroused considerable attention and study in the last few years. In the MESA New York Bight Atlas Monographs, Bowman and Wunderlich (1977) have summarized historic hydrographic data and portrayed the mean annual cycle of hydrographic properties, Hansen (1977) has described circulation, Yentsch (1977) has discussed the factors controlling primary production, Grosslein and Azarowitz (in press) have summarized the distribution of fish, McHugh and Ginter (1978) discussed the fisheries, and Malone (1977) has reviewed plankton systematics and distribution. In other studies, Han and Niedrauer (1981) recently reported on hydrography and mixing, Beardsley and Boicourt (1981) have summarized knowledge of atmospheric forcing over the continental shelf. Cook (1979a, b), Cook and Hughes (1980), and Hughes and Cook (1981) have portrayed the cross shelf and slope monthly thermal structure along a transect running southeastward out of New York City for the years 1976 through 1979. Judkins et al. (1980) reported on the composition, abundance, and distribution of zooplankton over a yearly cycle in the New York Bight.

In order to increase our understanding of the interaction between plankton, the environment, and the living marine resources, the Ship of Opportunity-Ocean Monitoring Program (SOOP) of the U.S. National Marine Fisheries Service in January 1976 began conducting monthly sampling for surface salinity, water column

temperature, and plankton at 10 m along a transect running southeastward from New York harbor to approximately lat. 38°30' N, long. 72°00' W. This route is one of several monitored monthly by the SOOP. The plankton sampling effort is part of a cooperative agreement with the Institute for Marine Environmental Research of the United Kingdom to extend their more than 35-yr standardized plankton survey into the western North Atlantic. Previous descriptions of the biology and ecology resulting from this study may be found in Smith and Marrero (1976) and Smith and Jossi (1979). This paper reports on the first 2 yr of plankton variations along one transect of this extended coverage, and includes data from other sources which are relevant to these variations.

## METHODS

### Plankton Sampling

Net phytoplankton and zooplankton at a depth of 10 m from the waters overlying the continental shelf and slope were collected from ships of opportunity by towing Hardy Continuous Plankton Recorders (CPR's) (Hardy 1939; Fig. 1) along routes lying within the envelope shown in Figure 2.

A continuous record of the plankton retained by the sampler is obtained along the track of the ship at one sampling depth. This record is cut into 18.5 km (10 nmi) sections (herein termed "samples") with times, dates, and positions calculated for their centerpoints. Water passing through the CPR is filtered with bolting silk having mean aperture dimensions of 225 × 234 µm.

The CPR mesh size allows most phytoplankton to pass through. Therefore, the samples are quantitative for only the largest members of the phytoplankton, and those taxa whose chains, horns, spines, setae, or gelatinous sheaths or threads cause them to become entangled in the silk fibers. Abundances of these quantitative taxa

<sup>1</sup>Northeast Fisheries Center Atlantic Environmental Group, National Marine Fisheries Service, NOAA, RR 7, South Ferry Road, Narragansett, RI 02882.

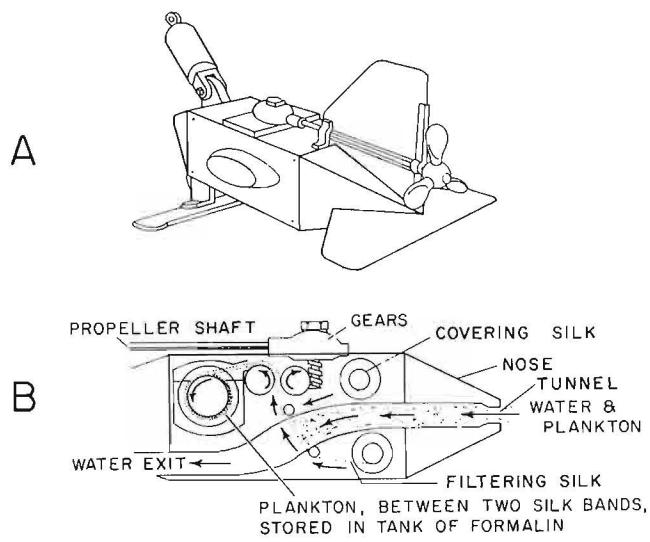

Figure 1.—The Hardy continuous plankton recorder. A. Seen from the left rear. B. Section showing the paths of the seawater and plankton and the two bands of bolting silk.

are not additive because the retention rates vary with their sizes and shapes. However, the retention rate of each of these taxa is constant enough to show the timing of events at 10 m, and often in the entire mixed layer. The qualitative taxa in the samples are valuable in establishing the presence of exotic specimens along the transect. They also assist in defining the temporal and spacial distribution of these forms.

### Phytoplankton Examination

Phytoplankton taxa were identified by examination of 20 microscopic fields (approximately 1/6,986th aliquot) distributed randomly across the sample. The number of occurrences of each taxon per 20 fields was converted to the number of that taxon in the 20 field aliquot by a statistical method of Colebrook (1960). Finally, an aliquot factor was applied to calculate the number of phytoplankton per liter of water filtered.

Beginning with the May 1977 data, a crude, but potentially useful, estimate of total phytoplankton was employed. It involved comparing the intensity of green color on the sections of filtering silk with a set of three color standards (Colebrook and Robinson 1961). Average values for the categories (very pale green, pale green, and green) were in the ratios of 1 to 2 to 6.5. We determined these relative numerical values for the period May 1977-January 1978.

### Zooplankton Examination

Zooplankton were examined from both the filtering silk and the covering silk (Fig. 1). Most of the zooplankton are retained in a quantitative manner. Exceptions are nauplii, copepodites, and small adult copepods (*Farranula*, *Oncaeaa*, *Corycaeus*, *Oithona*, and other small or gelatinous plankton). All the larger zooplankton ( $\geq 2$  mm) in the sample were identified and their numbers were recorded by abundance categories. Estimates of the mean abundances of these categories are reported here. This method is described by Colebrook (1960). The same method was applied to counts of smaller zooplankton ( $< 2$  mm) seen in an aliquot (approximately 1/45th) of the sample (actual aliquot fraction depended on the rate of silk advance through the CPR during each tow).

### Temperature and Salinity Measurements

Expendable bathythermograph probes (XBT's) were dropped and surface water samples were collected for salinity determination at approximately 18 km intervals. Sea surface salinity/XBT transects were occasionally made at times in addition to those when the CPR was towed.

Contoured vertical temperature profiles were prepared from XBT traces by Cook (1979a, b), Cook and Hughes (1980), and Hughes and Cook (1981). Plankton sample locations were plotted on these temperature profiles to determine the samples' relation to water mass boundaries, slope water intrusion, and shelf water entrainment around eddies. Sample temperatures (the 10 m temperatures of the sample center positions) were read from the XBT traces. If an XBT drop was not made at a sample center position, then a 10 m temperature was linearly interpolated from adjacent XBT drops.

A sea surface salinity value of 34.5‰ was used as a boundary to distinguish the fresher shelf water from the more saline slope water. If a salinity sample was not taken at a plankton sample center position, then a salinity value was obtained by linearly interpolating from adjacent observations.

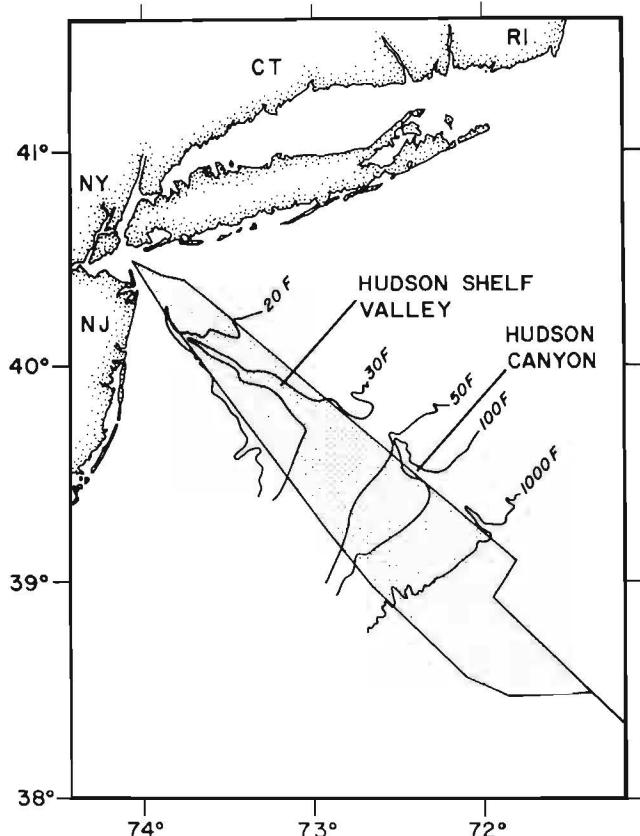

Figure 2.—The New York Bight with an envelope including the routes along which Hardy continuous plankton recorder samples and expendable bathythermograph and sea surface salinity data were collected, January 1976 to January 1978. Isobaths indicate depths in fathoms.

Satellite imagery, as portrayed by the U.S. Navy Oceanographic Office in the weekly Experimental Ocean Frontal Analysis<sup>2</sup> charts, also was used to help determine the positions of the shelf water/slope water front and Gulf Stream eddies.

## RESULTS

Appendix Tables 1-20 list plankton abundance from all analyzed samples arranged by month. The water masses, sea surface salinities, and 10 m temperatures are listed for each sample where available. Table 21 names the plankton taxa sampled in this survey.

Monthly abundance of selected net phytoplankton taxa in shelf and slope water is shown in Figures 3 and 4, and monthly abundance of copepods in shelf and slope water is shown in Figure 5. Monthly abundance of tropical and subtropical zooplankton is compared with the occurrence of Gulf Stream eddies adjacent to the continental shelf in Figure 6.

### Effects of Warm Core Gulf Stream Eddies on Plankton

The greater occurrence of eddies in 1977 corresponded with more frequent occurrence of tropical and subtropical net phytoplankton taxa (Table 22). In 1976, there were three such occurrences in shelf water and three in slope water, while in 1977 such taxa occurred in these water masses 27 and 17 times, respectively.

Note break in abundance scale.

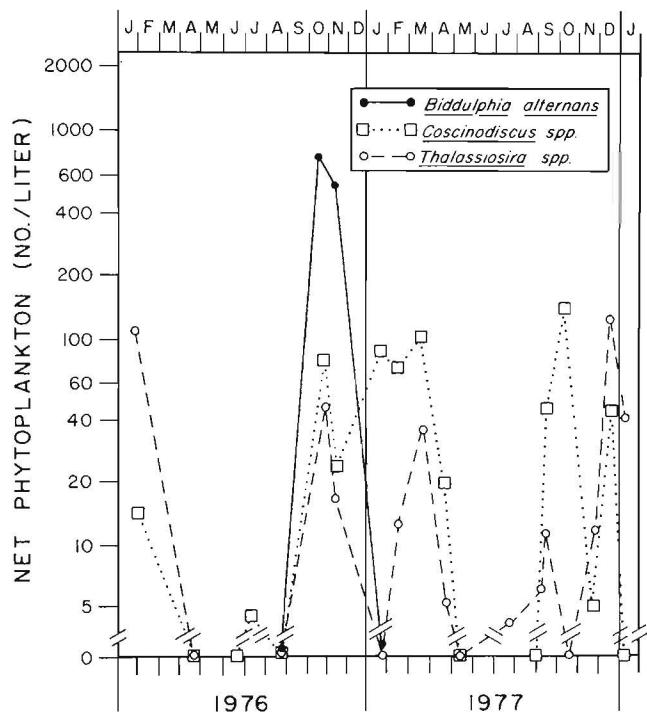

Figure 4.—Monthly mean abundance of the net phytoplanktonic diatoms *Biddulphia alternans*, *Coscinodiscus* spp., and *Thalassiosira* spp. in continuous plankton recorder samples taken from the New York Bight shelf water, January 1976 to January 1978. Note break in abundance scale.

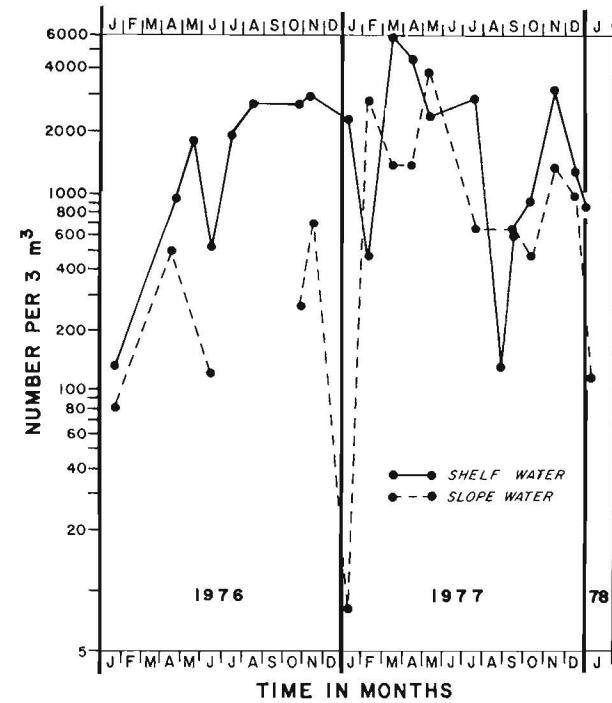

Figure 5.—Monthly mean abundance of copepods in continuous plankton recorder samples taken from the New York Bight shelf and slope water, January 1976 to January 1978.

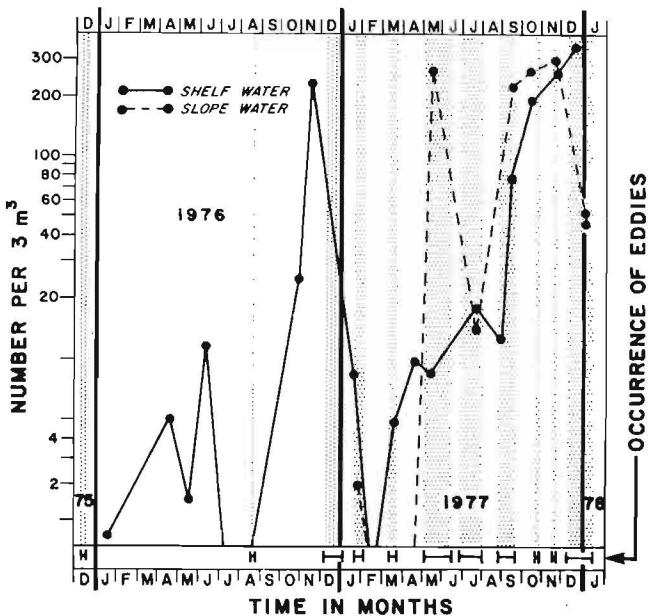

Figure 6.—Monthly mean abundance of tropical-subtropical zooplankton in continuous plankton recorder samples taken from the New York Bight shelf and slope water, January 1976 to January 1978. Occurrence of Gulf Stream eddies at the edge of the continental shelf, December 1975 to January 1978, is shown by the bars along the horizontal axis.

Gulf Stream eddies injected tropical and subtropical zooplankton into the shelf water. Figure 7 shows an intrusion of eddy water and a mixing of eddy-slope-shelf water at about 45 m in November 1977. Figure 8 shows another eddy pushing 13° and 14°C water onto the shelf in December 1977. CPR sample no. 8 (Table 19) was collected from the tongue of 13°C water at a depth of 10 m. It contained more tropical-subtropical zooplankton ( $701/3\text{m}^3$ ) than any other shelf water sample ( $372/3\text{m}^3$  or less) during December. This suggests that at least some of the tropical-subtropical zooplankton in the shelf water in this month came from this tongue of mixed eddy-slope-shelf water (see Table 22 for a list of tropical-subtropical plankton). Tropical-subtropical zooplankton (Fig. 6) occurred in shelf water in every season, primarily during or after the passage of Gulf Stream eddies along the shelf break. These eddy water intrusions appear to be an important mechanism for altering the biota of the shelf environment.

Gulf Stream eddies are also shown removing shelf water from the continental shelf at the surface in Figures 9 and 10 and at depths to 40 m in Figures 8 and 10. One would expect that shelf water plankton would likewise be removed by this entrainment, and that slope or eddy water intrusions might occur to replace the lost shelf water. We found the shelf water copepod *Calanus finmarchicus* in these entrainment features at abundances ranging from one- to two-thirds of the maximum abundance of this species in shelf samples during these months.

### Effects of Wind Events on Plankton

Wind induced offshore Ekman transport, which can cause upwelling, corresponded generally with the unusual timing of two of the phytoplankton maxima shown in Figure 3. Mean monthly Ekman transport data (Fig. 11) show a greater magnitude of offshore transport (upwelling) during May to July 1976 than for the same period of 1977. This coincides with much higher *Ceratium tripos*

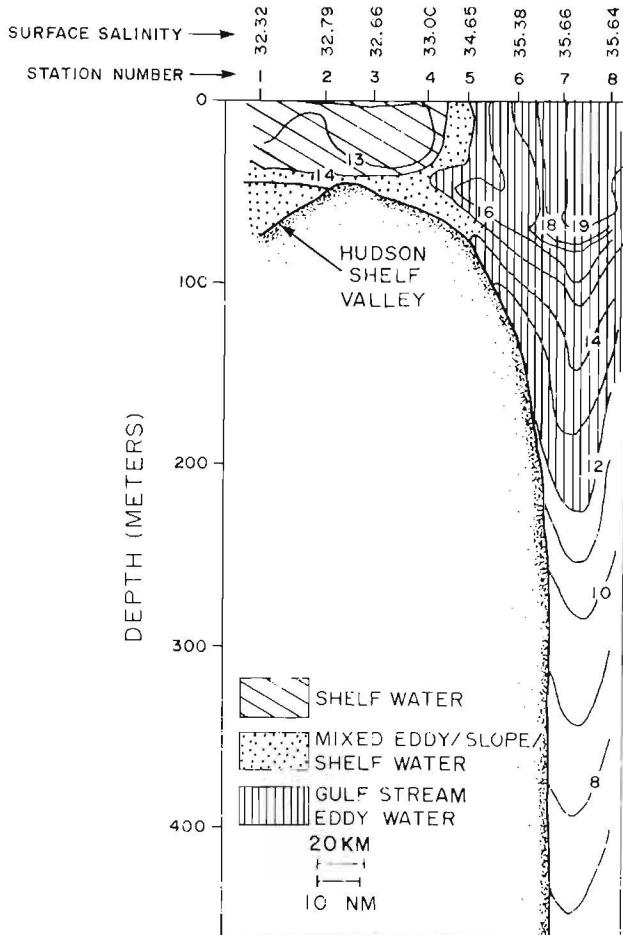

Figure 7.—Sea surface salinity (‰) and water column temperature (°C) distribution along a transect running southeastward from Ambrose Light, N.Y., 19-20 November 1977. A Gulf Stream eddy is seen pushing warm water onto the shelf and 15°C water occupies the portion of the Hudson Shelf Valley transected. (Modified from Cook 1979b.)

*tripos* concentrations, and a longer duration of what appears to be its spring bloom during that period in 1976 than 1977 (Fig. 3). *Ceratium tripos* increased during another episode of offshore transport in August 1977.

Two phytoplankton maxima that corresponded with wind induced mixing events were 1) the August 1976 *Thalassionema* and *Rhizosolenia* maxima which were recorded 4 d after the passage over the transect (10 August 1976) of Hurricane Belle, and 2) the August 1977 *C. tripos* maxima which began about the time of the passage of a cold front which caused mixing of surface water with some of the subthermocline cold pool (Cook 1979b), and continued during the above-mentioned period of offshore Ekman transport in August 1977.

Wind induced currents altered the distribution of tropical-subtropical plankton after eddies had injected it onto the shelf. In December 1977, (Table 19, Fig. 8), there was a relatively high concentration of tropical-subtropical zooplankton ( $372/3\text{m}^3$ ) in sample no. 3 which was collected from the Hudson Shelf Valley. This was 93 km ( $\approx 50$  nmi) inshore of the highest concentration (sample no. 8 =  $701/3\text{m}^3$ ) collected from the tongue of mixed eddy-slope-shelf water sampled in the same month. We believe that these tropical and subtropical plankton were transported by a bottom current moving up the Hudson Shelf Valley in response to

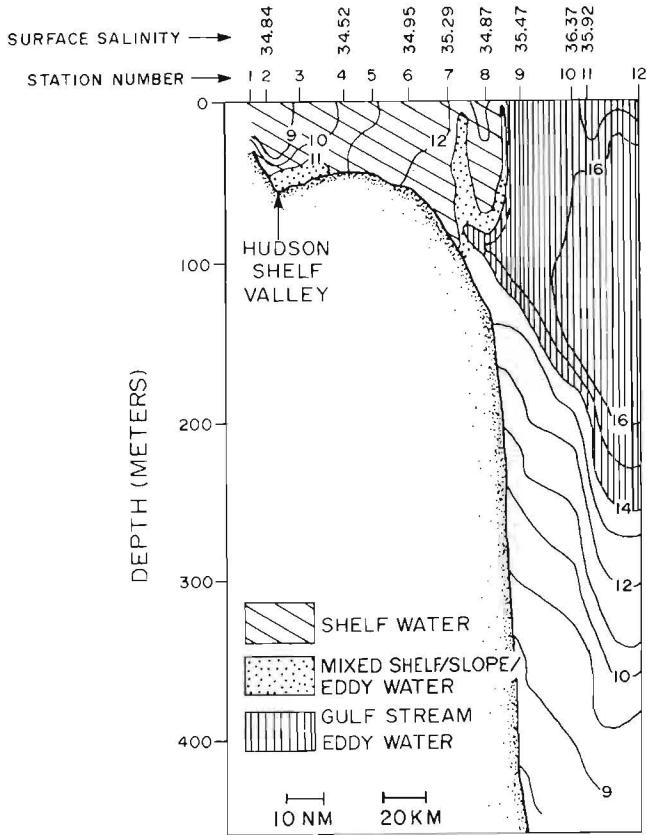

Figure 8.—Sea surface salinity (%) and water column temperature ( $^{\circ}\text{C}$ ) distribution along a transect running southeastward from Ambrose Light, N.Y., 17-18 December 1977. A Gulf Stream eddy is seen pushing  $13^{\circ}\text{C}$  water onto the shelf. Relatively warm water occupies the portion of the Hudson Shelf Valley transected. (Modified from Cook 1979b.)

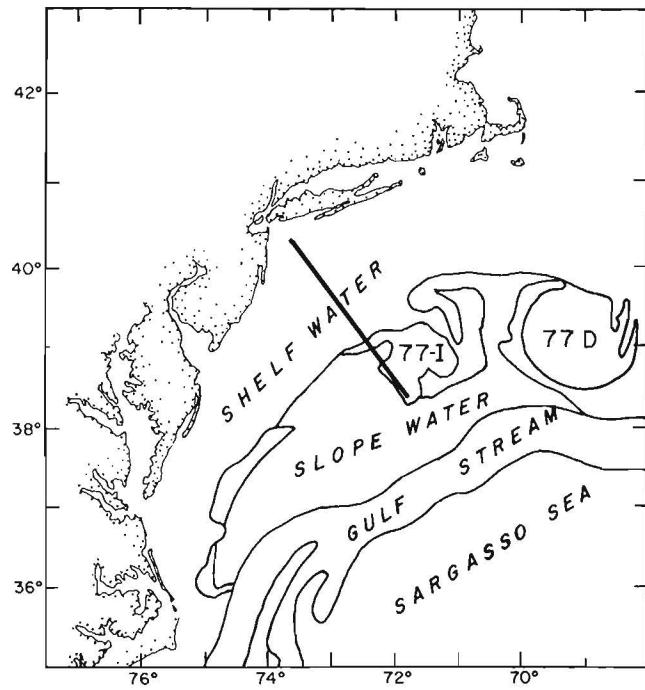

Figure 9.—Hardy continuous plankton recorder, expendable bathythermograph, and sea surface salinity transect, 17-18 December 1977, shown in relation to a composite of the surface water masses of 14 and 21 December 1977. (Modified from U.S. Naval Oceanographic Office.) Note the tongues of shelf water extending offshore to the east of eddy 77-I and 77D.

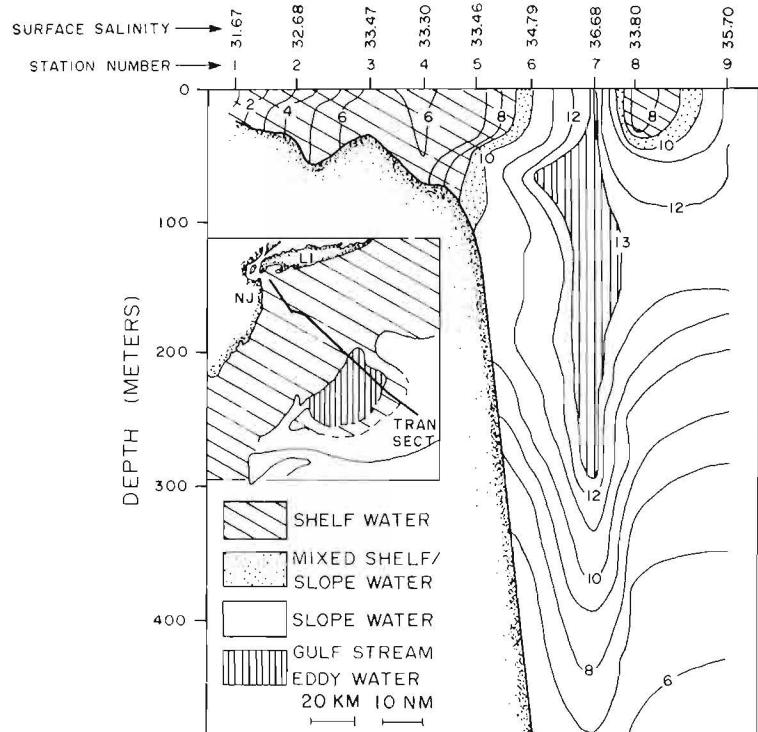

Figure 10.—Water column temperature ( $^{\circ}\text{C}$ ) distribution along a transect running southeastward from Ambrose Light, N.Y., on 12 February 1978 showing mass of shelf water  $< 10^{\circ}\text{C}$  seaward of a Gulf Stream eddy. The inset shows the areal distribution of water masses on 16 February. (Modified from U.S. Naval Oceanographic Office.)

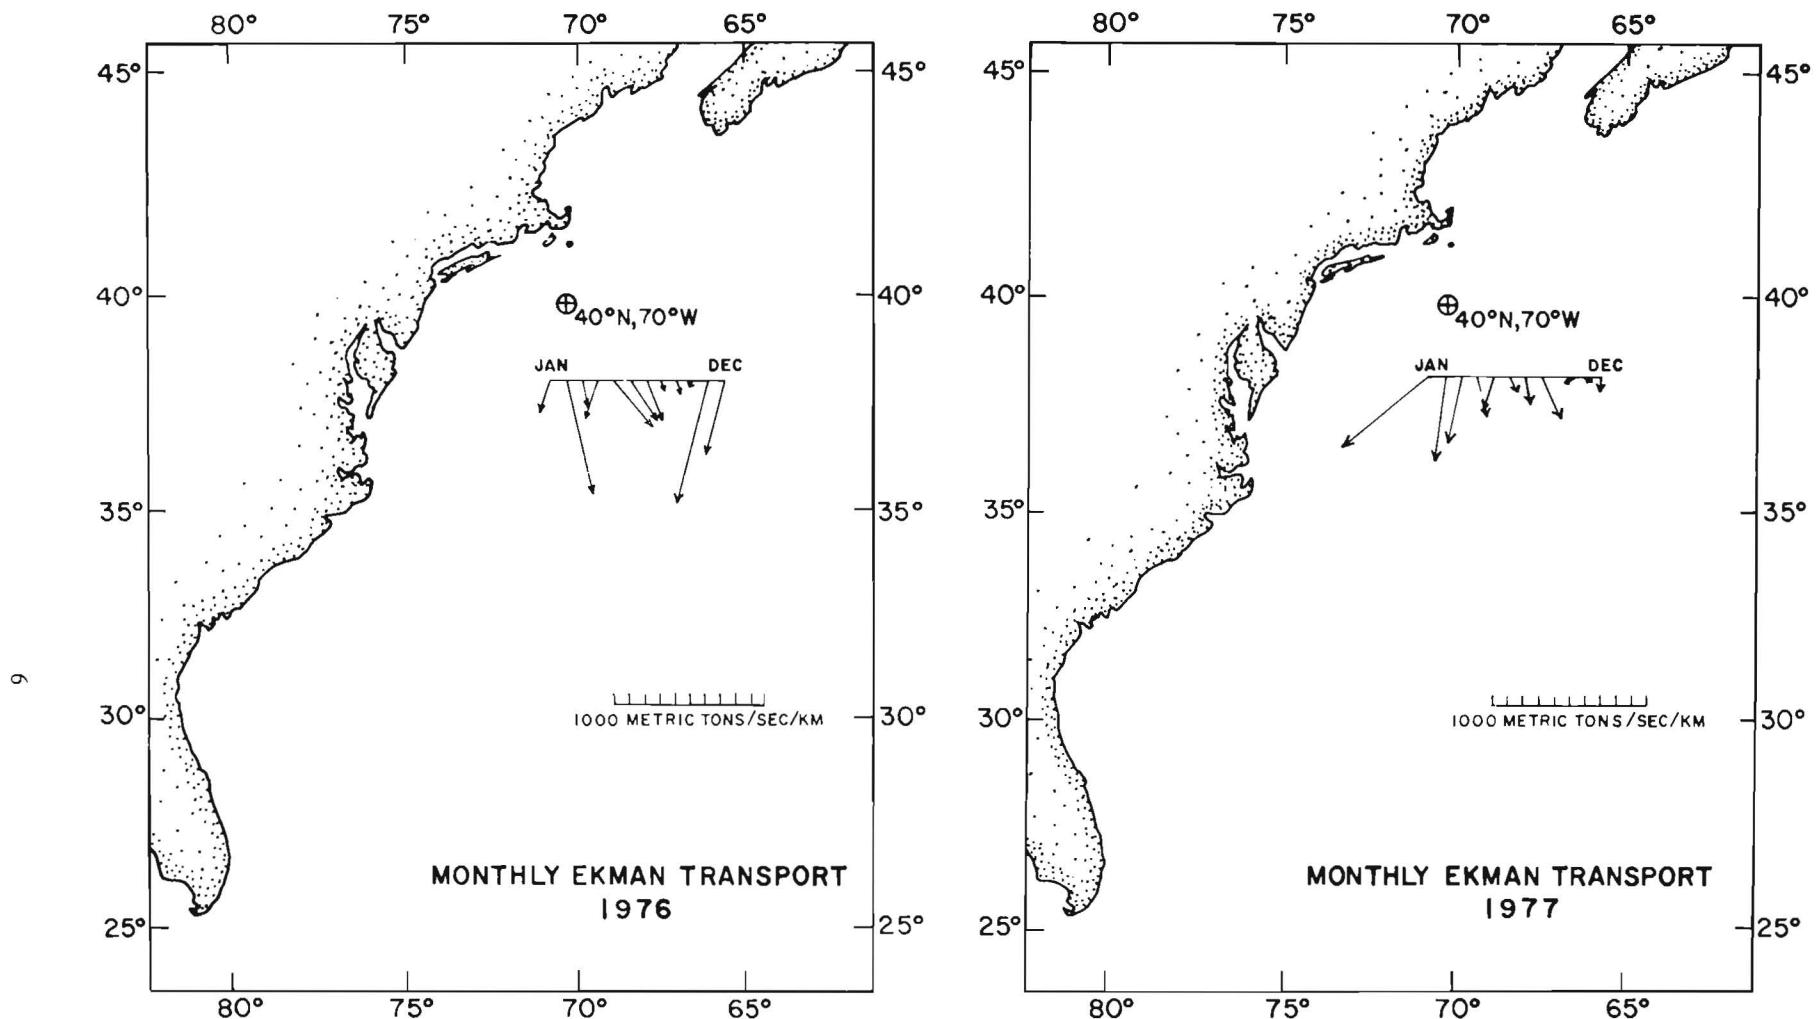

Figure 11.—Monthly mean Ekman transports for lat. 40°N, long. 70°W during 1976 and 1977. (From Ingham 1979a, b.)

northwest winds. From current meter data, Han<sup>3</sup> reports that such a current begins from as far offshore as the 60 m isobath and moves at speeds up to 20 cm/s. Nelson et al. (1978) also discussed this current in the upper Hudson Shelf Valley. Other evidence for this current having moved relatively warm, saline eddy or slope water containing tropical and subtropical plankton across the shelf is the increase of bottom temperatures from 11° to 15°C between October and November 1977 (Figs. 12, 7), and the rise in shelf water sea surface salinities from an average of 32.69‰ in November 1977 to an average of 34.22‰ in December 1977 (Figs. 7, 8). Neither the temperature nor the salinity increases can be solely attributed to fall overturn since bottom temperatures increased in November to values greater than any in the water column in October, and shelf water salinities sufficient to cause the measured salinity changes would be extremely rare. In December 1977 the Hudson Shelf Valley current transported tropical-subtropical plankton to within 30 km of Ambrose Light. This was 137 to 165 km shoreward of the surface expression of the eddies which were present during November and December. When other water masses are present in

the shelf valley, other taxa would be expected to be transported cross-shelf by this mechanism.

## CONCLUSIONS

Higher abundances of net phytoplankton in shelf water coincided with wind-induced offshore Ekman transport and with wind-induced mixing events. Two midsummer net phytoplankton maxima followed wind-induced mixing resulting from the passage of a cold front and Hurricane Belle.

Tropical-subtropical plankton were captured over the shelf primarily during and after the passage of Gulf Stream eddies. Eddies brought them over the mid- to outer-shelf, and onshore transport of water up the Hudson Shelf Valley distributed them further inshore. These data support the conclusion of Cox and Wiebe (1979) that tropical plankton in the Middle Atlantic Bight come from Gulf Stream eddies. The Hudson Shelf Valley probably also funnels outer-shelf plankton inshore when there is no Gulf Stream eddy water in the outer valley.

## ACKNOWLEDGMENTS

We thank the staffs of the U.S. Coast Guard, Atlantic Area, Marine Services Division, the U.S. Coast Guard Oceanographic Unit, and the officers and crews of the Coast Guard cutters *Dallas*, *Gallatin*, *Tamara*, and *Morganthau*. Also, we are indebted to the Sea Education Association, the officers and crew of their research vessel *Westward*, and the owners, officers, and crews of the tugs *Crusader* and *Port Jefferson*.

We also wish to thank Steven Cook and Robert Benway for their skillful handling of the logistics of the Ship of Opportunity Program and Merton Ingham and John Colton for their guidance in the preparation of the manuscript.

Table 16.—Plankton and environmental data from the New York Bright shelf and slope water, 13-14 September 1977. Watermasses: SH = shelf water; SL = slope water; E = Gulf Stream warm core eddy water. Abundances: phytoplankton, number per liter; zooplankton, number per 3 cubic meters. Organisms observed in the sample, but absent in the aliquot, are indicated by a "+" sign. A "\*" indicates that data are unavailable.

Table 21.—List of species and coarser taxa identified in CPR samples from the New York Bight, 26 January 1976–2 January 1978. Authorities used in identification are cited below the taxon name.

Cyanophyceae

Trichodesmium spp. Ehrenberg  
(Wille, 1908)

Bacillariophyceae

Centricae

- Bacteriastrum spp. Shadbolt  
(Hendey, 1964)  
Biddulphia alternans (Bailey) Van Heurck  
(Hendey, 1964)  
Chaetoceros (Hyalochaete) Ehrenberg (Gran)  
(Hendey, 1964)  
Chaetoceros (Phaeoceros) Ehrenberg (Gran)  
(Hendey, 1964)  
Corethron criophilum Castracane  
(Hendey, 1964)  
Coscinodiscus spp. Ehrenberg  
(Hendey, 1964)  
Ditylum brightwellii (T. West) Grunow  
(Cupp, 1943)  
Hemiaulus spp. Ehrenberg  
(Cupp, 1943)  
Nitzschia seriata Cleve  
(Cupp, 1943)  
Rhizosolenia alata f. alata Brightwell  
(Hendey, 1964)  
Rhizosolenia alata f. gracillima (Peragallo) Gran  
(Cupp, 1943)  
Rhizosolenia alata f. indica (Peragallo) Gran  
(Cupp, 1943)  
Rhizosolenia calcar-avis Schultze  
(Cupp, 1943)  
Rhizosolenia hebetata f. semispina (Hensen) Gran  
(Hendey, 1964)  
Rhizosolenia imbricata v. shrubsolei (Cleve) Schroeder  
(Hendey, 1964)  
Rhizosolenia setigera Brightwell  
(Hendey, 1964)  
Skeletonema costatum (Greville) Cleve  
(Cupp, 1943)  
Thalassiosira spp. Cleve  
(Cupp, 1943)

Pennatae

- Asterionella glacialis Cleve & Moller ex Gran  
(Cupp, 1943)  
Navicula spp. Bory  
(Cupp, 1943)  
Nitzschia closterium (Ehrenberg) Wm. Smith  
(Hendey, 1964)  
Thalassiothrix frauenfeldii Grunow  
(Hendey, 1964)  
Thalassiothrix longissima Cleve & Grunow  
(Hendey, 1964)  
Thalassionema nitzschioides Hustedt  
(Hendey, 1964)

Dinophyceae

- Ceratium carriense Gourret  
(Wood, 1968)  
Ceratium extensum (Gourret) Cleve  
(Wood, 1968)  
Ceratium furca (Ehrenberg) Claparede et Lachmann  
(Wood, 1968)  
Ceratium fusus (Ehrenberg) Dujardin  
(Wood, 1968)  
Ceratium hexacanthum Gourret  
(Wood, 1968)  
Ceratium horridum (Cleve) Gran  
(Wood, 1968)  
Ceratium incisum (Karsten) Jorgensen  
(Wood, 1968)  
Ceratium karstenii Pavillard  
(Wood, 1968)  
Ceratium kofoidi Jorgensen  
(Wood, 1968)  
Ceratium lineatum (Ehrenberg) Cleve  
(Paulson, 1908 & Wood, 1968)  
Ceratium longipes (Bailey) Gran  
(Paulson, 1908)  
Ceratium longirostrum Gourret  
(Wood, 1968)  
Ceratium macroceros (Ehrenberg) Vanhoffen  
(Wood, 1968 & Paulson, 1908)  
Ceratium massiliense (Gourret) Jorgensen  
(Wood, 1968)  
Ceratium minutum Jorgensen  
(Wood, 1968)  
Ceratium schroeteri (Schroder)  
(Wood, 1968)  
Ceratium setaceum Jorgensen  
(Wood, 1968)

Dinophyceae  
(cont'd)

Ceratium trichoceros (Ehrenberg) Kofoed  
(Wood, 1968)  
Ceratium tripos (O. F. Muller) Nitzsch  
(Paulsen, 1908)  
Ceratocorys spp. Stein  
(Wood, 1968)  
Dinophysis spp. Ehrenberg  
(Wood, 1968)  
Goniaulax spp. Diesing  
(Wood, 1968)  
Gymnodinium spp. Stein  
(Wood, 1968)  
Oxytoxum scolopax Stein  
(Wood, 1968)  
Oxytoxum spp. Stein  
(Wood, 1968)  
Protoperdinium spp. (Ehrenberg)  
(Wood, 1968)  
Prorocentrum spp. Ehrenberg  
(Wood, 1968)

Silicoflagellatae

Protozoa

Tintinnidae

Foraminifera

Coelenterata

Siphonophora

Other Coelenterata

Annelida

Polychaeta

Tomopteris spp. Eschscholz

Arthropoda Crustacea

Cladocera

Evadne spp.  
(Gosner, 1971)  
Penilia spp.  
(Gosner, 1971)  
Podon spp.  
(Gosner, 1971)

Ostracoda

Copepoda

Copepod nauplii

Calanoida

Acartia spp. Dana  
(Wilson, 1932)  
Acartia danae Giesbrecht  
(Wilson, 1932)  
Acartia tonsa Dana  
(Wilson, 1932)  
Calanus finmarchicus sensu stricto (Gunnerus)  
(Fleminger & Hulsemann, 1977)  
Calanus minor Claus  
(Owre & Foyo, 1967)  
Calocalanus spp. Giesbrecht  
(Wilson, 1932)  
Candacia armata (Boeck)  
(Wilson, 1932)  
Candacia curta (Dana)  
(Owre & Foyo, 1967)  
Candacia longimana (Claus)  
(Owre & Foyo, 1967)  
Candacia norvegica (Boeck)  
(Wilson, 1932)  
Candacia pachydactyla (Dana)  
(Owre & Foyo, 1967)  
Centropages bradyi Wheeler  
(Owre & Foyo, 1967)  
Centropages hamatus (Lilljeborg)  
(Wilson, 1932)  
Centropages typicus (Kroyer)  
(Wilson, 1932)  
Centropages velificatus (Dana)  
(Owre & Foyo, 1967)  
Clausocalanus spp. Giesbrecht  
(Wilson, 1932 & Rose, 1933)  
Eucalanus attenuatus (Dana)  
(Owre & Foyo, 1967)

Calanoida  
(cont'd)

- Eucalanus monachus (Giesbrecht)  
(Owre & Foyo, 1967)  
Eucalanus mucronatus Giesbrecht  
(Owre & Foyo, 1967)  
Euchaeta acuta Giesbrecht  
(Owre & Foyo, 1967)  
Euchaeta marina (Prestandrea)  
(Owre & Foyo, 1967)  
Euchaeta norvegica Boeck  
(Wilson, 1932)  
Euchirella pulchra (Lubbock)  
(Owre & Foyo, 1967)  
Euchirella rostrata (Claus)  
(Owre & Foyo, 1967)  
Labidocera aestiva Wheeler  
(Owre & Foyo, 1967)  
Lucicutia flavigornis (Claus)  
(Owre & Foyo, 1967)  
Mecynocera clausi J. C. Thompson  
(Owre & Foyo, 1967)  
Metridia lucens Boeck  
(Wilson, 1932)  
Mesocalanus tenuicornis (Dana)  
(Owre & Foyo, 1967)  
Paracalanus-Pseudocalanus spp. Boeck  
(Wilson, 1932)  
Paracalanus spp. Boeck  
(Wilson, 1932)  
Pleuromamma abdominalis (Lubbock)  
(Owre & Foyo, 1967)  
Pleuromamma borealis (F. Dahl)  
(Rose, 1933)  
Pleuromamma gracilis (Claus)  
(Rose, 1933)  
Pleuromamma robusta (F. Dahl)  
(Rose, 1933)  
Pleuromamma xiphias (Giesbrecht)  
(Rose, 1933 and Owre & Foyo, 1967)  
Pseudocalanus minutis Kroyer  
(Wilson, 1932)  
Rhincalanus cornutus (Dana)  
(Owre & Foyo, 1967)  
Rhincalanus nasutus Giesbrecht  
(Owre & Foyo, 1967)  
Scolecithrix danae (Lubbock)  
(Owre & Foyo, 1967)  
Temora longicornis (O. F. Muller)  
(Wilson, 1932)  
Temora stylifera (Dana)  
(Owre & Foyo, 1967)  
Temora turbinata (Dana)  
(Owre & Foyo, 1967)

**Calanoida**  
(cont'd)

- Tortanus discaudatus (Thompson & Scott)  
(Wilson, 1932)  
Undinula vulgaris (Dana)  
(Owre & Foyo, 1967)

**Cyclopoida**

- Copilia spp. Dana  
(Owre & Foyo, 1967)  
Corycaeus spp. Dana  
(Owre & Foyo, 1967)  
Oithona spp. Baird  
(Wilson, 1932)  
Farranula gracilis Wilson  
(Owre & Foyo, 1967)  
Oncaeaa spp. Philippi  
(Owre & Foyo, 1967)  
Sapphirina spp. J. V. Thompson  
(Owre & Foyo, 1967)

**Harpacticoida**

- Clytemnestra spp. Dana  
(Wilson, 1932)  
Macrosetella gracilis (Dana)  
(Wilson, 1932)

**Cirripedia**

- Lepas Linnaeus

**Amphipoda**

- Caprellidea  
Gammaridea  
Hyperiidea

**Cumacea**

**Mysidacea**

**Stomatopoda**

**Euphausiacea**

**Decapoda**

**Penaeida**

**Sergistidae**

- Lucifer spp.  
(Gosner, 1971)

Mollusca

Cephalopoda

Gastropoda

Thecosomata

Lamellibranchia

Chaetognatha

Chordata

Thaliacea

Larvacea

Fishes

Myctophidae

Lepidophanes guentheri

Bothidae

Paralichthys oblongus

Scombridae

Scomber scombrus
