Molecular Targeting in Inflammatory Bowel Disease

An investigation to identify novel chemokine targets for the potential development of new therapeutic agents for inflammatory bowel disease

Abstract

Purpose

Inflammatory bowel disease is characterised by intense mucosal recruitment of activated leukocytes. As chemokines determine inflammatory leukocyte recruitment and retention, the expression of the entire chemokine family within colonic mucosa from IBD patients was compared to non-inflamed and inflamed controls.

Methods

A microarray of cDNAs, representing the entire chemokine superfamily and their cognate receptors, was hybridised with probes derived from colonoscopic biopsies. While expression levels of individual chemokines and their receptors have been measured in colon tissue previously, no one has attempted to analyse transcription levels of the entire chemokine superfamily in parallel. The array levels were correlated with histopathological inflammatory scores and expression of their cognate receptors by quantitative PCR and immunohistochemistry. Flow cytometry was performed on mucosally-derived colonic cells. Caco-2, HT29, T84, primary colonic epithelium and keratinocyte cell lines were stimulated with combinations of IL-1β, TNF-α, and LPS, and analysed using the same microarray.

Results

Expression of a distinct subset of chemokines, consisting of CXCL's 1-3 and 8 and CCL20, was up regulated in active colonic IBD, compared to non-inflamed areas or tissue from controls. This expression pattern correlated with histopathological inflammatory scores. Increased expression of their cognate receptors, CXCR1, CXCR2 and CCR6, was confirmed by quantitative PCR and immunohistochemistry. Flow cytometric revealed an increase of CCL20 expression on epithelial cells in IBD specimens, particularly in severe disease. An identical chemokine response was induced in Caco-2 cells by stimulation with IL-1β, but not TNF-α. By contrast, IL-1β and TNF-α were synergistic in HT29 and keratinocytes.

Conclusion

IL-1β and TNF-α appear to be the pivotal mediators of a coordinated epithelial chemokine response that dominates the mucosal environment in ulcerative colitis. These data suggest several new therapeutic targets for IBD, as well as identifying a previously unrecognised coordinated epithelial chemokine response.

Acknowledgements

My sincere thanks go to my supervisors, Professor Roy Pounder and Dr Adam Platt. I am grateful for a rewarding time of research, working as part of such an enthusiastic and inspirational team. Thank you for all the encouragement, guidance and patience.

Thank you to Simon Murch, not only for your imaginative, insightful contribution, but also for your warm welcome into the Department of Paediatric Gastroenterology. I am grateful to all the members of this department, for your help and friendship, in particular to Paul Ashwood, Stephanie Auld, Alan Phillips and Franco Torrente.

I would also like to thank the entire Department of Adult Gastroenterology, for a thoroughly enjoyable time at the Royal Free Hospital. It was a joy to work in such a friendly, cohesive unit. Thanks to Ashley Brown and Mark Hamilton for advice on write-up, and thank you to Professor Gazzard, Catherine Dunbar, Ann-Marie Brandom and my mother for proof-reading the manuscript, and for the constructive criticism.

Thank you to Rosalind Sim and John Auld from the Department of Pathology, for training me in the techniques of immunohistochemistry, and for making the time truly enjoyable. Thank you to Richard Morris for statistical assistance, and to Simon Thomas for Mac back up.

I am grateful to Celltech for sponsoring much of this work, especially to Richard Gellinas and his team of collaborators in Seattle, Washington. Thank you also to Shavy Makh, Celltech Slough for guidance in cell culture experimentation.

The magnitude and complexity of the universe mirrored by the unfathomable intricacies of molecular biology speak of hands of the one whose depth of beauty lies beyond all definition or comprehension. Were a man to study a cell for a lifetime, he would merely be as a child learning to read for the first time. Before the creator of all that I see and understand, and all that I do not, I bow down.

Statement of problem and challenge underlying this research thesis

The chronic inflammatory bowel diseases (IBD) include Crohn's disease (CD) and ulcerative colitis (UC). CD is characterised by patchy, granulomatous transmural ulceration of the gastrointestinal tract. It occurs at any location in the bowel, most frequently at the terminal ileum. The chronic inflammation of UC is superficial to the muscularis mucosae, extending variable distances from the rectum proximally around the colon.

Current therapies offered for CD and UC are frequently inadequate at controlling these diseases, and the associated side effects limit their application. If the disease becomes intractable, surgical intervention is sometimes required, and there is a significant risk of malignancy (Bernstein et al, 2001), (Rhodes et al, 2002), (Sharan et al, 2002). These diseases are therefore common and important conditions for which the identification of precise immune targets could lead to more specific therapy, with enhanced therapeutic benefit and fewer associated side effects.

This MD sets to answer the following questions:

1 Which chemokines and their receptors are central to the disease processes in IBD?
2 Expression patterns of individual chemokines have been previously investigated, but is there a particular coordinate response to inflammatory stimuli in IBD?
3 What is the effect of pro-inflammatory cytokines on the chemokines identified?
4 What is the potential for therapeutic intervention at a chemokine/chemokine receptor/pro-inflammatory cytokine level in IBD?

Details of collaborators and their contribution to this research are detailed in appendix 6.

1.10 Regulation of chemokine production

1.11 Molecular targeting in IBD

1.12 Outline of MD thesis

1.13 Microarray technology

1.1 Incidence of IBD

CD and UC are amongst the most common immune-mediated disorders in developed-world countries. There has been an unexplained rising incidence of IBD over the last century, most notably in Northern Europe and North America (Hildebrand et al, 1994), (Montgomery et al, 1998). The incidence has begun to stabilise at a high rate in most developed countries, and continues to rise in regions where IBD had been less common (Loftus et al, 2002). The prevalence rates in survey of the UK are 3.3 per 1,000 by age 26, and 5.1 per 1,000 by age 43 (Montgomery et al, 1998), (Thompson et al, 2000).

1.2 Aetiology of IBD

The cause of IBD is unknown, although environmental and genetic factors are both implicated in a multifactorial manner. The most popular current theory implicates a T lymphocyte disorder in genetically susceptible individuals as a result of a breakdown of regular constraints in the mucosal immune responses to enteric bacteria (Shanahan, 2002). A genetic component is likely as IBD case clustering is common within families and there is increased concordance in monozygotic compared to dizygotic twins, particularly with regard to CD (Binder et al, 1996), (Thompson et al, 1996), (Tysk et al, 1998), (Orholm et al, 2000). Furthermore, age of onset and phenotype correlate within monozygotic twins (Rampton et al, 1986). Early linkage study of the familial clustering indicated that chromosomes 3, 7, 12 and 16 contain potential candidate genes for IBD (Hugot et al, 1996). Subsequently, two groups identified a frameshift variant and missense mutation of the CARD15 gene located on chromosome 16, conferring susceptibility to CD overlapping with the IBD1 locus (Hugot et al, 2001), (Ogura et al, 2001). It is now thought that this gene accounts for 20% of the genetic susceptibility in CD, although the insertion mutation in the CARD15 gene does not confer susceptibility to UC (Hampe et al, 2001), (Hugot et al, 2003). Certain CARD15 allelic variants are increased in Ashkenazi Jews which may explain the high incidence of CD in this group (Bonen et al, 2003). However, the discovery of CARD15 merely contributes one more piece of the jigsaw puzzle, as CARD15 variants do not account for all of CD (Shanahan, 2002), and furthermore, patients with Blau syndrome (missense mutations in nucleotide binding domain of CARD15) do not exhibit IBD (Miceli-Richard, 2001). Other regions of linkage have been implicated in IBD include 12q13, MHC on chromosome 6p23 and chromosome 14q11-12 (Watts et al, 2002).

CARD15 proteins are intracellular receptors for various pathogen-associated molecular patterns in the gastrointestinal tract (Bonen et al, 2003). Colonic involvement in active CD is associated with increased CARD15 gene expression in macrophages and intestinal epithelial cells (Berrebiet et al, 2003). Following pathogen detection, the transcription factor NF-κB is activated, which modulates the innate immune response (Duerr, 2002), (Hugot et al, 2003).

Infection is likely to be an important factor, due to the interaction between bacterial peptides and the mucosa (Martin et al, 2000), (Leiper et al, 2001). A variety of causal infections have been proposed, such as *Mycobacterium para tuberculosis*, which causes granulomatous bowel disease in cattle (Hampson et al, 1989), (Sanderson et al, 1992), (Ryan et al, 2004).

One popular hypothesis implicates defects in epithelial barrier function and/or immunoregulation leading to an immune response that is triggered by antigenic components of normal flora (Basset et al, 2002). Consistent with this is evidence from transgenic mice lacking IL-2 or IL-10, who develop colitis only in a non-sterile environment (Kuhn et al, 1993), (Sadlack et al, 1993). Furthermore, patients with IBD have increased levels of IgG to enteric flora during active disease (Macpherson et al, 1996).

Genetic polymorphism causing aberrant expression of regulatory proteins such as IL-1 receptor antagonist (IL-1ra) may be of aetiological importance in IBD although data have been conflicting (Louis et al, 1996), (Hacker et al, 1997), (Mwantembe et al, 2001).

An environmental aspect to the aetiology of IBD is suggested by marked geographical variation, with migrating populations adopting the incidence of IBD of their destination, for example, Asian immigrants to the UK (Feehally et al, 1993).

A number of case reports indicate long-term remission in IBD following autologous bone marrow transplantation which suggests that the primary defect may be immunological, although it is not thought to be primarily autoimmune (Kashyap et al, 1998), (Lopez-Cubero et al, 1998), (Talbot et al, 1998). This transplantation phenomenon could merely represent a 're-setting' of a previously hyper-stimulated system, with the immuno-pathogenesis occurring as a secondary event.

Intestinal ischaemia and vasculitis occur in IBD, although whether this is a cause or effect phenomenon is unclear. Associated arterio-venous thrombosis may be critical to its pathogenesis. Resin cast studies of mesenteric vasculature from resected intestinal CD sections led one group to propose a primary vasculitic model for IBD. They observed that mucosal ulceration concorded with infarction at the muscularis propria level (Wakefield et al, 1989). This same group also postulated that the measles virus could be an aetiological agent in IBD, via a vasculitic process, as viral genomic products were detected in mucosal biopsies from patients with active IBD (Lewin et al, 1995). However, these findings have not been re-produced, and the theory remains controversial. Further evidence for a vasculitic process comes from the association of anti-neutrophil cytoplasmic antibodies (ANCA) with IBD (Cambridge et al, 1992). This antibody is also found in association with Wegener's granulomatous vasculitis. Thrombocytosis and increased platelet aggregation in response to IL-1 and IL-8 are part of the inflammatory response and are thought to be part of the vasculitic process (Collins et al, 1994), (Schaufelberger et al, 1994). This may contribute to the systemic thromboembolism and mucosal inflammation in IBD (Collins et al, 1994).

The relative significance of mucins in IBD has not as yet been characterised. Mucins are constituents of the semi-permeable barrier mucous between the lumen and the epithelium. They determine the thickness and properties of mucous, which is a crucial part of the immunological defense system of the gastrointestinal tract. There is alteration in both secretory and membrane bound mucins in IBD, which may be of aetiological importance (Shirazi et al, 2000), (Einerhand et al, 2002).

Dietary factors such as sugar intake have been suggested as risk factors for IBD, but data are at present conflicting (Krishnan et al, 2002). High intakes of mono- and polyunsaturated fat and vitamin B6 may enhance the risk of developing UC (Geerling et al, 2000). Food additives such as fluoride, titanium dioxide and alumino-silicates have been proposed to be of importance in this multifactorial model for IBD (Powell et al, 2000). Smoking is associated with increased CD activity and relapse, and conversely, smoking cessation is associated with the onset of UC (Calkins, 1989). This is thought to be an immunomodulatory effect, altering pro-inflammatory cytokines and leukocyte adhesion to endothelial cells, in addition to effecting intestinal motility (Finnie et al, 1996), (Bhatti et al, 1997), (Benoni et al, 1998).

1.3 Immune pathology in IBD

Inflammatory infiltrate in IBD

IBD is characterised by a destructive host inflammatory response directed in part against the mucosal epithelium. There is intense leukocyte recruitment and retention within the lesions. Characteristic tissue damage occurs through a final pathway of pro-thrombotic mechanisms and proteolytic degradation of the extracellular matrix (MacDonald et al, 1994).

The dense leukocytic infiltrate that occurs in IBD includes activated cells from both the innate and adaptive (acquired) immune systems. These two components work in co-operation, with chemokines functioning as a vital constituent of signalling between them. The innate system provides the initial line of defence, and includes phagocytes (macrophages and neutrophils) in addition to specialised granulocytes (eosinophils and basophils), necessary to engulf small pathogens and contain larger parasites (Matsukawa et al, 2000), (Luster 2002). The adaptive response involves both T and B cells, and is characterised by specificity and long-lasting memory (Luster 2002).

The intensity of the inflammatory response is determined by the local expression of growth factors and pro-inflammatory cytokines within the mucosa, and by coordinated mechanisms of cellular recruitment (Kunkel et al, 2002). The location of and interaction between immuno-competent cells is critical to any appropriate immune response (Kunkel et al, 2002). As such, control of leukocyte trafficking is key. It is chemokines, their receptors and vascular adhesion molecules that determine the extent, type and duration of cellular infiltration, by controlling the migratory paths of dendritic cells, and lymphocytes both in homeostasis and inflammation. This implicates their immunological centrality (Sallusto et al, 1998)[1]. However, it has not been established which chemokines are contingent, nor which members of the chemokine and chemokine receptor superfamily are specifically involved in chronic colonic inflammation in IBD. Their identification could potentially lead to the discovery of novel therapeutic targets for IBD therapy. In addition, research into these diseases is likely to aid the immunological characterisation of other epithelial organs, as UC and CD are notable exemplars of human chronic inflammatory disease. The gastrointestinal tract is particularly conducive to investigative study owing to the accessibility of the mucosal tissue. It is the largest part of the immune system, and consists of organised lymphoid tissues including Peyer's patches, intraepithelial

lymphocytes and scattered cell components such as lymphocytes and plasma cells in the lamina propria (Mowat et al, 1997).

Epithelial involvement in immunity

The intestinal epithelium is vital not only as a barrier, but also in the primary recognition of pathogenic organisms and the subsequent recruitment of inflammatory cells to the mucosa (Van Deventer et al, 1997). Intestinal integrity and permeability is of fundamental importance in intestinal immunity, and is governed by intercellular tight junctions. These are made up of highly regulated complex proteins, such as zonula occludens, which maintain the seal between adjacent cells (Fiocchi, 1997). Pro-inflammatory cytokines and infectious agents modulate such inter-cellular interactions. For example, interferon-γ (IFN-γ) can down-regulate zonula occludens, causing a significant decrease in trans-epithelial resistance, with a deficient control of antigen transit leading to uncontrolled gastrointestinal inflammation (Shao et al, 2001). Regulatory T cells are not only involved in suppression of the inflammatory response, but are also thought to aid preservation of tight junctional complex integrity (Shao et al, 2001). Patients with IBD have increased flux of antigen across both inflamed and non-inflamed mucosal areas, with abrogation of tolerance to luminal flora (Shao et al, 2001). This loss of mucosal integrity may lead to the ingress of luminal antigens into the lamina propria, and thus augment the inflammatory response (Williams et al, 2000).

The direct contact of the large surface area with the intestinal milieu renders it particularly susceptible to inflammation, with exposure to antigenic, mitogenic, mutagenic and toxic stimuli. This necessitates flexibility within the immune system, which occurs partly by adaptability of chemokines and their receptor expression by epithelial cells. These cells therefore develop characteristics usually attributable to classical inflammatory cell types in addition to their normal absorptive and secretary functions. Chemokines secreted by human intestinal epithelial cells signal to neutrophils, macrophages and lymphocytes, vital for the inflammatory response. This contributes to the integrated, tightly regulated multicellular response whereby the target cells contribute to inflammation (Yang et al, 1997).

The highly specialised membranous epithelial cells (M cells) are important in mucosal immunity, and exist only in conjunction with lymphoid aggregates. These cells take up particulate antigen and transport adherent macromolecules efficiently. The antigen is carried to the underlying sub-epithelial dome, where mature dendritic cells phagocytose and process the antigen and migrate to T cell-rich interfollicular regions for antigen-presentation to naïve lymphocytes (Sarsfield et al, 1996), (Cook et al, 2000). In contrast, intestinal epithelial cells have processing and presentation pathways, with classical MHC I and II and non-classical MHC 1b pathways in addition to organism specific routes of invasion. Epithelial toll like receptors (TLRs) and CARD15 are crucial in the communication of pathogen recognition to effect an appropriate chemokine response, via transcription factor activation including NF-κB (Aderem et al, 2000). The cellular response and chemokine induction depends on the type of pathogen (Kawai et al, 2001). LPS in conjunction with LPS-binding protein binds to CD14 surface receptor on macrophages and monocytes, which subsequently activates TLR4 to initiate chemokine and

cytokine release, including TNF-α, IL-6 and IL-1β (Kawai et al, 2001). Experimentally, agonists to TLR2 and TLR4 induce chemokine levels (Jones et al, 2001). The multitude of pathways through these cells reflects the diversity of antigen the gastrointestinal tract is exposed to daily (Shao et al, 2001). Although intestinal epithelial cells are not true phagocytes, they ingest soluble antigen by fluid phase pinocytosis, and are able to present antigen. These cells may also be able to take up antigen via receptor mediated endocytosis, though *in vivo* data is lacking (Shao et al, 2001).

In the normal state, the gastrointestinal tract contains abundant leukocytes in intra-epithelial and sub-epithelial compartments, rendering it in a state of 'physiological inflammation' (Monteleone et al, 2002). The effector cells include neutrophils, macrophages and cytotoxic T lymphocytes. These constitute the main aggressors acting either directly by physical contact, or indirectly through the release of soluble factors such as reactive oxygen species and nitrogen metabolites, cytotoxic proteins, lytic enzymes and cytokines. The reactive behaviour of the immune cells governed in part by the cytokine milieu, underlie the symptoms and structural changes in IBD, for example pain, dysmotility, fibrosis, stricturing, fistula formation and neoplastic transformation (Panja et al, 1998).

Recruitment of specific leukocyte subpopulations into gastrointestinal tissue occurs via high endothelial venules (HEVs), which constitute the specialised endothelial post capillary mucosal microcirculation. They are the main entry point into peripheral lymph nodes for lymphocytes (Fiocchi et al, 1997). Chemokines and adhesion molecules control this leukocyte recruitment in two stages. Firstly, they control extravasation from blood into lymph nodes, Peyer's patches or inflamed tissue; a step also dependent on selectins and integrins (Sallusto et al, 2000). Only four chemokines have thus far been shown to functionally arrest circulating leukocytes under physiological conditions: CCL21 (which arrests lymphocytes), CXCL1, CCL2 and CCL5 (which arrests monocytes). No chemokines have as yet been shown to arrest neutrophils under inflammatory conditions (Ley, 2003).

Selectins are present on, and mediate the initial interactions between endothelial cells and leukocytes. They are lectin-like adhesion molecules, comprised of transmembrane glycoprotein receptors (Juliano, 2002). The expression and function of selectin is highly regulated, enabling appropriate leukocytic recruitment. Of the subtypes E-, L- and P-selectin, L-selectin is predominant, and is expressed by most leukocytes, including naïve T cells, B circulating monocytes and neutrophils (Patel et al, 2002). Selectin is made and transported to the cell surface within four hours of IL-1 and TNF release from activated macrophages. The interaction between leukocyte L-selectin and P/E-selectin on endothelial cells causes the cells to roll along the endothelial lining at decreased velocity. Leukocyte tethering, rolling, activation and subsequent adhesion are essential for cellular recruitment. Progression from rolling to cessation is currently thought to occur within a few seconds of an initial rolling contact, although there is some evidence to indicate that activation of rolling leukocytes by chemoattractants can be gradual (Kunkel et al, 2000).

Following the rolling contact, progression ceases via integrins (Campbell et al, 1998). Integrins are transmembrane glycoproteins on the surface of most leukocytes that mediate adhesion among cells as well as within the extracellular matrix (Sims et al, 2002). Integrins pre-exist in predominantly inactive states on circulating immune cells and are activated *in situ* following encounter with endothelial displayed chemokines or ligands to specific G protein-couples receptors on the leukocyte surface (Alon et al, 2003). Integrins consist of one of 18α and 8β subunits (Juliano, 2002). β2 integrin is thought to be of particular importance, interacting with the endothelial cell intercellular adhesion molecule (ICAM-1). The α4 integrin is expressed on almost all lymphocytes, and exists in combination with a β1 or β7 subunit, which interacts primarily with the endothelial ligands vascular cellular adhesion molecule-1 (VCAM-1) and mucosal addressin cell adhesion molecule-1 (MAdCAM-1) respectively. The α4β1-integrin is important in inflammatory recruitment of leukocytes and in other sitations that require cell adhesion to the vascular endothelium (Chigaev et al, 2003). The avidity of the cells expressing the α4β1-integrin can be rapidly changed by chemokines (Chigaev et al, 2003). The α4β7-integrin interaction with MAdCAM-1 is crucial to the leukocyte gastrointestinal mucosal homing (Sandborn et al, 2002). MAdCAM-1 contains several structural motifs that are homologous with ICAM-1, VCAM-1, and IgA1, although also contains a unique mucin-like domain not shared by these molecules. It is expressed on the lamina propria venules and Peyer's patch HEVs, in the marginal zone of the spleen and in areas of chronic inflammation. L-selectin may also interact with MAdCAM-1 in the gastrointestinal tract. MAdCAM-1 expression is stimulated by TNF-α in HEVs via NF-κB translocation (Oshima et al, 2001).

Human intestinal micro vascular endothelial cells derived from IBD mucosa display enhanced adhesiveness for leukocytes compared with those derived from normal mucosa, in addition to enhanced vascular permeability (Gautman et al, 2001). This adhesion is modulated by pro-inflammatory cytokines such as monocyte/macrophage-derived TNF-α, which induce endothelial cells to produce IL-1, which in turn increases polymorphonuclear and monocyte cellular adhesion to the vascular endothelium. These interactions determine leukocyte infiltration and are pivotal in tissue damage (Fiocchi, 1997). Understanding such interactions could aid future development of therapeutic targets (Fiocchi, 1997).

The second stage in leukocyte trafficking involves cellular transmigration into the site of inflammation. Following extravasation from the blood, leukocytes pry apart the inter-endothelial cell connections and migrate into the site of inflammation under the control of chemokines and their receptors with 'multistep navigation' (Foxman et al, 1997). This requires sequential ligand-induced desensitisation mediated by specific GRK kinases that phosphorylate the engaged receptor (Premont et al, 1995), (Daaka et al, 1998). Thus, in conjunction with adhesion molecules, chemokines control the recruitment of specific leukocyte sub-populations to sites of tissue damage.

Oxygen and nitrogen reactive metabolites in IBD

Immune activation in IBD results in a sustained overproduction of reactive metabolites of oxygen and nitrogen, and there is over expression of the inducible form of nitric oxide synthase (iNOS)

(Grisham et al, 2002), (Pavlick et al, 2002). The oxidative injury correlates with disease severity, and it is thought that oxidative induced cytoskeletal disruption is a prerequisite to tissue damage (Keshavarzian et al, 2003). However, colonic oxidant levels have also been found to be elevated in normal mucosa of affected patients, indicating that an oxidative imbalance does not necessarily lead to tissue injury, nor is not entirely consequential to tissue injury (Keshavarzian et al, 2003). A number of studies have demonstrated that reactive oxygen NO species may promote gastrointestinal inflammation, although other studies do not support this. Furthermore, there is some evidence to suggest that some of the reactive oxygen species may play a protective role in IBD, and other evidence to implicate an imbalance of these reactive metabolites to be a contributory factor to some of the intestinal damage that occurs in IBD (Pavlick et al, 2002), (Kruidenier et al, 2003). There therefore remains a lack of clarity as to the relative importance of the enhanced production of reactive oxygen species and iNOS-derived nitric oxide (NO). Antioxidant agents may be of therapeutic benefit in IBD, and further research is required (Langmead et al, 2002). The antioxidant effects of aminosalicylates may constitute at least part of their therapeutic action.

Mucosal lymphoid tissue

Mucosal lymphoid tissue in the gastrointestinal tract provides immunological tolerance to dietary antigens and immunity to pathogens (Sarsfield et al, 1996). This ability to differentiate between pathogens and non pathogens is a crucial characteristic of the immune system. Lymphocytes activated in Peyer's patches tend to recirculate, or return to intestinal mucosa, facilitating re-encounter with the same antigen originally presented to them in the Peyer's patch (Cook et al, 2000).

Other intestinal cell types

The immunological significance of other intestinal cell types, including fibroblasts and myofibroblasts is yet to be defined. These cells may be pivotal in the chronicity of IBD, or may merely represent cells that undergo 'bystander damage' (Fiocchi, 1997). Intestinal sub-epithelial myofibroblasts are present close to the basal surface of epithelial cell. They have an important role in wound healing and fibrosis, and enhance epithelial cell migration via secreted bioactive transforming growth factor (TGF)-β (Fiocchi 1997), (Beltinger et al, 1999). Bacterial components directly activate intestinal myofibroblasts expressing TLRs. This may be crucial to the innate response by sensing and responding to bacterial products that have penetrated into the subepithelial compartment (Otte et al, 2003).

The role of the enteric nervous system in the control of inflammation has not yet been elucidated. It has been postulated to mediate broad modulatory activities in acute and chronic inflammation, with its extensive rich network of enteric fibres and neurotransmitters (Fiocchi, 1997). The enteric glial cell network has tropic and protective functions towards enteric neurons, functionally equivalent to astrocytes (Cabarrocas et al, 2003). Similar to the astrocytic regulation of the blood brain barrier, glial cells are thought to regulate mucosal and vascular permeability in the gastrointestinal tract, in addition to tissue integrity. Disruption of the glial network may be important in the pathogenesis of CD (Cabarrocas et al, 2003). Targeted deletion of enteric glial

cells in transgenic mice has yielded pathological changes similar to necrotising enterocolitis (NEC) and early CD, possibly implicating the significance of the enteric system in the pathogenesis of bowel disease (Bush et al, 1998). This is poignant as NEC shares some mechanistic and phenotypic similarities with IBD (Bush, 2002).

Extracellular matrix

All interactions between immune and non-immune cells in the gastrointestinal tract occur in the midst of a complex mixture of proteins including fibronectin, collagen, laminin, thrombospondin, tenascin, enactin, and proteoglycans. These proteins constitute two main domains; the compact laminar structure termed the basement membrane, and a diffuse network surrounding lymphoid, mesenchymal, vascular and nerve cells (Fiocchi, 1997). The extracellular matrix is important in regulating the number, location and activation of leukocytes, so is a vital non-immune constituent of the immune system. Interaction between the extracellular matrix and immune cells occurs via matrix metalloproteinases (MMPs) which are a homologous family of zinc dependent peptidases produced by T cells and macrophages whose enzymic activity is directed against components of the extracellular matrix (Fiocchi, 1997). They play a central role in tissue remodelling (Stamenkovic, 2003). The enzymic and corresponding mRNA levels are increased in and correlate with inflammation in IBD suggesting that matrix metalloproteinases may play an important role in gastrointestinal inflammation (Pender et al, 1997), (Heuschkel et al, 2000). An imbalance between these enzymes and their natural inhibitor may be central to degradation. For example MMP3 is markedly up-regulated in ulcerated tissue, although the tissue inhibitors of metalloproteinases (TIMP1) remains unchanged (Heuschkel et al, 2000).

1.4 Chemokine overview

Chemokines are essentially chemo-attractive cytokines produced by immune and non-immune cells, including epithelial cells (Papadakis et al, 2000), (Hoover et al, 2002), (Standyk, 2002). They are small (8-14kDa), structurally related, mostly basic that bind heparin and are stored in secretary granules to be mobilised as required (Rollins et al, 1997), (Sallusto et al, 2000). In the cytotoxic granules of cytotoxic T lymphocytes, chemokines are stored together with proteoglycans and perforin in a form that is particularly effective in inhibiting HIV infection (Sallusto et al, 2000). Following stimulation with histamine or thrombin, the contents of these granules are transferred to the cell surface, allowing rapid leukocytic recruitment without the need for protein synthesis (Sallusto et al, 2000). Most are secreted, and tend to remain relatively local (Standyk, 2002). They form stable gradients as they are positively charged, so bind to sulphated proteoglycans in the extracellular matrix or on the cell surface (Webb et al, 1993). Their effects are transduced following ligation of one or more of nineteen specific G-protein coupled receptors, expressed predominantly on leukocytes. Appropriate immobilisation is important for the control of immunological effect (Sallusto et al, 2000). A few chemokines, such as fractalkine are expressed on the cell surface (Olson et al, 2002).

Chemokine function

Chemokines are of fundamental importance in the control of leukocyte trafficking and recruitment. For example, CCL21 production is both required and sufficient for β2-integrin

activities upon rolling T cells in peripheral lymph node HEVs (Stein et al, 2000). They work co-operatively, sometimes with directionally opposing gradients, such as occurs with monocytes, driven out from blood vessels into tissue (Ogilvie et al, 2003). Chemokines also modulate haemopoeisis, angiogenesis and tissue repair, and inhibit HIV infection (Baggiolini et al, 1998), (Sallusto et al, 1998)[2]. Furthermore, they are important in dendritic cell maturation, T and B cell development, and in Th1 and Th2 responses (Rossi et al, 2000). In addition to their immunological centrality, chemokines have also been implicated in cancer and autoimmune diseases (Ajuebor et al, 2002)[2].

Chemokine up regulation occurs in response to pro-inflammatory cytokines and to enteric pathogens directly, including bacteria, bacterial products, and chemical stimuli (Panja et al, 1998). For example, butyrate regulates expression of CXCL2, CXCL3 and CXCL8 in intestinal epithelial cells. This is a short chain fatty acid derived from the fermentation of non-absorbed carbohydrate by intestinal bacteria (Huang et al, 1997), (Fusunyan et al, 1998).

Chemokine classification

More than 50 chemokines have been identified, each with a specific pattern of cellular chemotaxis (Ono et al, 2003). The development of bioinformatics (computer-assisted sequence analysis) on expressed sequence tag databases has allowed the expansion of chemokine identification. Chemokines are ideal for such analysis owing to their small size, abundant expression and because they are secreted proteins (Zlotnik et al, 2000), (Yoshie et al, 2001).

Chemokines are categorised into four distinct families CXC (α group), CC (β group), CX_3C (δ group), and C (γ group), and differentiated structurally according to the number and spacing of the amino-terminal cysteines (Rossi et al, 2000), (Sallusto et al, 2000), (Zlotnik et al, 2000). CC chemokines have two adjacent amino-terminal cysteines, whereas CXC chemokines possess an intervening amino acid between the two amino-terminal cysteines (Rollins et al, 1997), (Baggiolini et al, 1997). Two disulphide bonds are formed between the first and third Cys and between the second and fourth Cys. Lymphactin is the exception to the four Cys rule, and has only two Cys residues, so it retains a functional structure with only one disulphide bond (Rossi et al, 2000). The chemokines and their pseudonyms are listed in table 1.1.

Table 1.1: Chemokines, chemokine receptors and their alias names

Chemokine	Alias names	Receptor
CXC group		
CXCL1	GRO1 (growth regulated protein), GROα, MGSA (melanoma growth stimulatory activity), SCYB1, NAP-3	CXCR1, CXCR2
CXCL2	GRO2, GROβ, MIP2α, SCYB2	CXCR2
CXCL3	GRO3, GROγ, MIP2β, SCYB3	CXCR2
CXCL4	PF4, Platelet Factor-4, SCYB4	Unknown
CXCL5	SCYB5, ENA-78, SCYB5	CXCR2
CXCL6	SCYB6, GCP-2, SCYB6	CXCR1, CXCR2
CXCL7	PPBP, (PBP>CTAP-III>β-TG>NAP-2), SCYB7, low-affinity platelet factor 4	CXCR2
CXCL8	IL-8, SCYB8, MDNCF, NAP-1, LYNAP, NAF, GCP-1	CXCR1, CXCR2
CXCL9	MIG (monocyte induced by IFγ), SCYB9	CXCR2, CXCR3
CXCL10	INP10, γ IP10, SCYB10	CXCR2 CXCR3
CXCL11	I-TAC (IFN-α inducible T cell α chemoattractant), β-R1, IP9, H174, SCYB11	CXCR2 CXCR3
CXCL12	SDF-1α, SDF-β, PBSF, SCYB12, TPAR1, TLSF	CXCR4
CXCL13	BCA-1, BLC, SCYB13	CXCR5
CXCL14	BRAK, bolekine, SCYB14	Unknown
CXCL15	Lungkine	Unknown
CXCL16	Small inducible cytokine B6	CXCR6
CC group		
CCL1	SCYA1, I-309, TCA-3	CCR8
CCL2	SCYA2, MCP-1 (monocyte chemotactic protein), MCAF, HC11	CCR2
CCL3	SCYA3, MIP-1α, MIP-1αS, LD78α, GOS19-1, PAT 464.1, TY-5, SISα	CCR1, CCR5
CCL4	SCYA4, MIP-1β, ACT-2, PAT744, H400 SIS-γ, LAG-I, HC21, G-26, MAD-5	CCR5
CCL5	SCYA5, SIS-δ, RANTES (regulated upon activation, normal thymus expressed and secreted)	CCR1, CCR3, CCR5
CCL6	C-10, MRP-2	CCR1, CCR2, CCR3
CCL7	SCYA7, MCP3 (monocyte chemotactic protein), NC28, FIC	CCR1, CCR2, CCR3
CCL8	SCYA8, MCP-2, HC14	CCR2, CCR3
CCL9		CCR1
CCL10		CCR1
CCL11	SCYA11, Eotaxin	CCR3
CCL12	SCYA12, MCP-3	CCR2
CCL13	SCYA13, MCP-4, CK β 10, NCC-1	CCR2, CCR3
CCL14	SCYA14, CC-1, HCC-1, NCC-2, CK β1, CCCK-1/CCCK-3, MCIF, MIP1δ	CCR1
CCL15	SCYA15, HCC-2, leukotactin-1 (Lkn-1) MIP5, CC-2, NCC-3	CCR1, CCR3
CCL16	SCYA16, HCC4, LEC, NCC-4, LMC monotactin-1 (Mtn-1), LCC-1, ILINCK	CCR1
CCL17	SCYA17, TARC (thymus and activation-regulated chemokine), STCP-1	CCR4
CCL18	SCYA18, DC-CK-1, PARC, MIP-4 AMAC-1, CK β 7	Unknown
CCL19	SCYA19, MIP-3α, ELC, exodus-3, CK β 7	CCR7
CCL20	SCYA20, MIP-3α (macrophage inflammatory protein-2α), LARC (liver and activation-regulated chemokine), exodus-1, CK α 7	CCR6
CCL21	SCYA21, 6Ckine, SLC, exodus-2, TCA4, CK β 9	CCR7
CCL22	SCYA22, MDC, STCP-1	CCR4

CCL23	SCYA23, MPIF-1, MIP-3, CK β 8-1	CCR1
CCL24	SCYA24, MPIF-2, eotaxin-2, CK β 6	CCR3
CCL25	SCYA25, TECK, CK β15	CCR9
CCL26	SCYA26, Eotaxin-3, MIP-4 α	CCR9 (GPR9-6)
CCL27	SCYA27, Eskine, CTACK, ILC, skinkine	Unknown
CCL28	Novel CK - ligand for CCR10	CCR10
C group		
XCL1	SCYC1, lymphotactin α, SCM-1α, ATAC	XCR1
XCL2	SCYC2, lymphotactin β, SCM-1β, ATAC	XCR1
CX_3C group		
CX_3CL1	SCDY1, Fractalkine, CX3X ligand	CX3CR1

Chemokine receptor	**Alias names**	**Ligand**	**Chromosome**
CCR1	CC CKR1, HM145, MIP-1α/R, MIP-1α/RANTES	CCL2 (with low affinity insufficient to signal) 3, 4, 5, 7, 8, 13, 14 (potent agonists for CCR1), 15, 16, 23	3
CCR2	CC CKR2A, CC CKR2B, MCP-1RA, MCP-1RB	CCL2, 7, 8, 13	3
CCR3	CC CKR3, CMKBR3, CKR-3	CCL5, 7,11	3
CCR4	CC CKR4, K5-5	CCL17, 22 (highly potent agonists with high receptor affinity)	3
CCR5	CC CKR5, CMKBR5, ChemR13	CCL 3, 4, 5, 8	3
CCR6	DRY6, CKR-L3, GPR-CY4, STRL22	CCL20	6
CCR7	EB1, BLR2	CCL19, 21	17
CCR8	ChemR1, TER-1, GPR-CY6, CKRL1	CCL21	3
CCR9	GPR-9-6	CCL25	3
CCR10	GPR2	CCL27, 28	17
CXCR1	IL-8R1(type A), Type 1 IL-8R	CXCL8	2
CXCR2	IL-8R2(type B), Type 2 IL-8R	CXCL1, 2, 3, 5, 6, 8, 9, 10, 11	8
CXCR3	IP10/MIGR, MIG, I-TAC	CXCL9, 10	8
CXCR4	LESTR, HUMSTER, HM89 LESTR, NPYRL, LCR1, Fusin	CXCL12	2
CXCR5	BLR1, MDR15	CXCL13	11
CXCR6	Bonzo, TYMSTER, STRL33		3
CX_3CR1	V28, CMKBRL1, GPR13	CX3CL1	3
XC1	GPR5	XCL1, 2	3

Human chemokine binding proteins

Receptor	**Alias**	**Ligands**	**Chromosome**
DARC	Duffy antigen	CCL2, 5 CXCL1, 8	1
CCX, CKR	CCR10, PPR1	CCL19, 21, 25	
D6	CCR10, JAB61	CCL2, 4, 5, 7, 8	3

(Horuk, 2001), (Zlotnik et al, 2000)

Distinct patterns of chemokine expression have been seen in different diseases, with CXC chemokines largely involved in recruitment of neutrophils and monocytes and CC chemokine are more strongly implicated in lymphocyte and dendritic cell recruitment (Papadakis et al, 2000), (Zlotnik et al, 2000). The C family of chemokines exert their actions on T lymphocytes and NK cells. The CX_3C chemokine fractalkine is active on T lymphocytes, NK cells, monocytes and neutrophils (Ajuebor et al, 2002)[1].

Chemokines may also be categorised into 'inflammatory' and 'lymphoid' groups. Inflammatory chemokines are produced by several cell types at high levels, including endothelial, epithelial, stromal cells and leukocytes, and are important in acute and chronic inflammation. This group includes CXCL8, CXCL10, CCL2, CCL4, CCL5 and CCL11, which are largely involved in recruitment of neutrophils and macrophages, and are induced by inflammatory stimuli such as LPS, IL-1β or TNF-α. The production of these chemokines varies according to the type of inflammation, for example CCL11 is found at high levels in the lung undergoing allergic inflammation (Sallusto et al, 2000). Lymphoid chemokines are produced within lymphoid tissue and maintain homeostatic leukocyte traffic and cell compartmentalisation within these organs. This group includes the CC chemokines. Some chemokines function as inflammatory or lymphoid chemokines depending on the environment. For example, CCL22 functions as an inflammatory chemokine when it is produced in the inflamed lung but can also contribute to the regulation of intercellular interactions in the secondary lymphoid organs (Sallusto et al, 2000).

The majority of chemokines are produced in a variety of tissues and locations, although some remain restricted to a particular tissue, such as CCL25 which is only produced in the thymus and intestine (Sallusto et al, 2000).

Chemokine receptors

Chemokines are biologically active via binding to cell surface receptors. Expression frequently varies according to the stage of celleular activation and differentiation (Ono et al, 2003). Various chemokine receptors have been cloned so far, including six CXC, ten CC, one CX_3C and two C receptors (Horuk, 2001). In many cases chemokine receptors are promiscuous, binding several chemokines within a single class with high affinity. CCR6 is an exception, with only two known ligands: CCL20 and β-defensin (Perez-Canadillas et al, 2001). CXCR1-5 bind CXC chemokines, CCR1-9 bind CC chemokines, XCR1 binds the C chemokine, lymphactin, and CXCR1 binds the CX_3C chemokines such as fractalkine (Rossi et al, 2000), (Horuk, 2001). These are members of superfamily of serpentine proteins that signal through G-protein coupled, seven-transmembrane receptors. Chemokine binding to a cognate receptor causes conformational changes in the chemokine, enabling N-terminal initiation of a signalling cascade of intracellular events that lead to biological action (Fernandez et al, 2002). There is a dissociation of the receptor associated G proteins into α and βγ subunits, which activates a variety of effector enzymes, including phospholipases, leading to inosital phosphate production, an increase in intracellular calcium and activation of protein kinases (Horuk, 2001). This signal transduction causes activation of chemotaxis by modulating actin-dependent cellular processes, up regulation of adhesion proteins, in addition to a variety of functions in leukocytes (Horuk, 2001).

1.5 Cellular control by chemokines

Dendritic cells

Dendritic cells are bone marrow derived antigen-presenting cells that are widely distributed throughout lymphoid and non-lymphoid tissues, although in relatively small numbers (Cravens et al, 2002). They prime or tolerise T lymphocytes thus initiating or inhibiting immune responses,

migrating to secondary lymphoid organs to present antigen to T lymphocytes in the T-zones (McColl, 2002). Recruitment of these cells from the bone marrow to the site of injury or infection is determined both by chemokines produced in a time specific manner, and by the ability of these cells to respond via their chemokine receptors at different stages of maturation (Luster 2002), (McColl, 2002). Dysregulation of dendritic cell migration is thought to contribute to the dendritic cell accumulation in the lesions of autoimmune disorders (Cravens et al, 2002).

The receptors CXCR1, CXCR2, CCR1, CCR2 and CCR5, CCR6 are present on immature dendritic cells and their precursors monocytes. These receptors account for the extravasation and migration of these cells into inflamed tissues. CXCR1 and CXCR2 probably account for the arrest of rolling monocytes (Sallusto et al, 1994). CCR6 expression is restricted to immature dendritic cells, explaining their strong response to its cognate ligand CCL20 which is highly expressed by intestinal epithelial cells in low basal levels, contrasted with high levels after stimulation (Carramolino et al, 1999), (Kucharzik et al, 2002), (Vanbervliet et al, 2002). Dendritic cells respond to various pathogen-associated molecular patterns such as LPS, bacterial lipoproteins, peptidoglycan and CpG dinucleotides via their several different receptor types. These include CD14, scavenger receptors and TLR2, 3, 4, 5, 6, 9 (Luster, 2002). Stimulation of these receptors induces dendritic maturation, which is characterised by the production of pro-inflammatory cytokines, up regulation of co-stimulatory molecules and altered expression of chemokine receptors (Olson et al, 2002). A 'chemokine gradient' enables the immature dendritic cells to encounter stimuli such as IL-1, TNF-α and LPS that facilitate maturation (Sallusto et la, 1994), (Randolph et al, 1998), (Cella et al, 1999). In contrast, IL-10 causes a down-regulation of antigen presenting cell function of many dendritic cells (Macdonald et al, 1999).

Following stimulation, dendritic cells initially produce large amounts of CCL3, CCL4 and CXCL8 for a short period of time. CCL2 and CCL5 are also produced, but in a steadier fashion (Olson et al, 2002). This pattern of expression enhances and sustains the recruitment of immature dendritic cells and other inflammatory cells. Pro-inflammatory cytokines secreted by activated macrophages bind to dendritic cell receptors and mediate cessation of phagocytosis and departure from the tissue to the nearest lymph node via the lymphatic system (Olson et al, 2002). This process is accompanied by a marked change in chemokine receptor expression, contributing to maturation. In the maturing dendritic cell, there is a rapid down-regulation of receptors that respond to inflammatory chemokines (i.e. CCR1, CCR5, CCR6), a loss in their responsiveness for the chemokine ligands for those receptors (CCL3, CCL4, CCL5, CCL20) and an up regulation of lymphoid chemokines such as CXCR4, CCR4 and CCR7 (Sallusto et al, 2000), (Skelton et al, 2003). This enables responsiveness to the chemokines CCL12, CCL17, CCL19, CCL21 and CXCL13 (Dieu et al, 1998), (Sallusto et al, 1998)[3], (Izadpanah et al, 2001), (Luster 2002). The CCR7-binding chemokines CCL19 and CCL21, and the CXCR5-binding chemokine CXCL13 are the primary mediators of dendritic cells and lymphocytes into secondary lymphoid tissue (Lindhout et al, 1999), (Reif et al, 2002). CCR7 ligands have a key role in the accumulation of antigen-loaded mature dendritic cells in T cell rich areas of draining lymph nodes (Sallusto et al, 1994), (Caux et al, 2002).

In the regional lymph nodes, dendritic cells are the primary cells responsible for activating naïve T and B cells, which then return to the site of inflammation and are also involved in the re-stimulation of experienced T-cells in the tissue. The interaction between dendritic cells and lymphocytes has a key role in linking innate and adaptive responses (Luster et al, 2002). T cell proliferation induced by dendritic cells yields either a Th1 or Th2 response depending on the cytokine environment and length of time of stimulation (MacDonald et al, 1999), (Sallusto et al, 2000).

T cell changes during inflammation:

Within 6 hours of inflammatory stimulation of T cell receptors, a transient switch in chemokine receptor expression occurs. There is a down-regulation of T-cell expression of CCR1, CCR2, CCR3, CCR5, CCR6, CXCR3, and an up regulation of CCR4, CCR7, CCR8 and CXCR5. The up regulation of CCR7 enables T cell migration to draining lymph nodes, with relocation of the cells to the sites where the receptors correspond to the newly expressed ligands, i.e. CCL19, CCL21 (CCR7 ligands), CXCL13, CCL1, CCL17 (Sallusto et al, 2000), (Stein et al, 2000). CCL21 is expressed in HEV, which facilitates cellular migration. In the regional lymph nodes, the naïve T cells are stimulated by antigen presenting cells.

The balance between Th1 and Th2 cells and between pro-inflammatory and anti-inflammatory cytokines is maintained by chemokines (Siveke et al, 1998). Th1 T cells secrete IFN-γ and IL-2, which up-regulates the Th1-attracting chemokines CCL3, CCL4 and CCL5 (Siveke et al, 1998), (Pavlick et al, 2002). CCL3 and CCL4 also induce the influx of NK cells, macrophages and immature dendritic cells. NK cells are an important source of IF-γ. IF-γ also induces expression of the T-cell recruiting chemokines CXCL9 and CXCL10 (Luster, 2002). CXCL10 is also induced directly by viruses and bacterial products, and thus may play an early role in T and NK cell recruitment into tissue (Luster, 2002). This is antagonised by Th2 attracting chemokines and IL-4. The receptors preferentially expressed by Th1 cells include CXCR3, CCR1 and CCR5 (Campbell et al, 2000). The expression of CCR1 and CCR5 explains Th1 co-localisation with macrophages and neutrophils in delayed type hypersensitivity lesions (Homey et al, 1999). Both Th1 and Th2 cells secrete CCL2 and CXCL12 (Sieveke et al, 1998). TNF-α is associated with Th1 and Th2 responses, and stimulates both types (Sallusto et al, 2000).

Examples of Th1-mediated diseases include rheumatoid arthritis and MS (Balashov et al, 1999), (Nanki et al, 2000). Nearly all T cells in the MS lesions express CCR5 and CXCR3, although usually only 5-15% of peripheral blood T cells have this phenotype. Production of IFN-γ, a cytokine that is a hallmark of Th1 type immune responses, is important to the pathogenesis of this disease. Increased production of IFN-γ precedes clinical attacks and injection of MS patients with recombinant IFN-γ induces exacerbations of the disease (Balashov et al, 1999), (Qin et al, 1997). Skin homing T cells are mainly Th1. It has been postulated that CD is a Th1-mediated response and UC a Th2-mediated response, based on the respective cytokine profiles in the gut, differentiating them immunologically (Scheerens et al, 2001), (Siegmund, 2002), (Weigmann et al, 2002).

Th2 cells secrete IL-4, 5, 9, 10 and 13, which probably stimulates the effector function of eosinophils and basophils, in addition to enhancing CCL11 and CCL22 production, thus amplifying and modulating the inflammatory reaction (Sallusto et al, 2000), (Montelone et al, 2002), (Pavlick et al, 2002), (Weigmann et al, 2002). This is counter-acted by IFN-γ production. Th2 cells express CCR4 (receptor for CCL17, CCL20 and CCL22), also expressed on basophils (Nagata et al, 1999), CCR8 (receptor for CCL1 and CCL21) (Nagata et al, 1999), CCR3 (receptor for CCL11, produced abundantly in mucosal tissues undergoing allergic inflammation) and CCR5. CCR5 is produced at lower levels on Th2 cells compared to Th1 cells. Eosinophils and basophils both express CCR3, which facilitates their co-localisation at sites of CCL11 production (Sallusto et al, 2000).

Th2 cells are important in atopic and allergic disease processes, contrasting with Th1 cell mediated delayed type hypersensitivity reactions such as contact allergic responses (Homey et al, 1999). CCR4 and CCR8 are examples of potential Th2 targets for therapeutic intervention, although the pathophysiological role in these diseases needs to be further investigated.

Memory T cells

A fraction of the activated T lymphocytes become memory cells that migrate throughout the peripheral tissues and possess rapid effector function. They undergo clonal expansion in lymph nodes. Memory T cells efficiently interact with E-/P-selectin and VCAM-1. They also express multiple chemokine receptors including CCR4 and CCR6. CCR6 may aid cellular migration in response to CCL20 both in the skin and gastrointestinal tract (Sallusto et al, 2000).

There are 2 types of memory T cells. Both types are more sensitive to T cell receptor stimulation than naïve T cells, and consequently stimulate dendritic cells more efficiently to produce IL-12. The first group constitutes a rapid effector group that can be rapidly recruited to inflamed peripheral tissues, where they perform delayed type hypersensitivity or cytotoxic functions, required to rapidly contain invasive pathogens. These cells lack CCR7, express low levels of L-selectin, high levels of integrins, and produce effector cytokines IFN-γ and IL-4. The second group of memory T cells constitute a lymph-node-homing, non-polarised phenotype. These express CCR7 and express high levels of L-selectin. They do not produce effector cytokines, and represent a pool that stimulate dendritic cells generate new waves of effector cells (Sallusto et al, 2000).

A subset of memory T cells preferentially migrates to gut or skin. Those that home to skin possess 'cutaneous lymphocyte associated antigen' (CLA), which binds E-selectin on endothelial cells of inflamed skin. CLA constitutes a carbohydrate modification of P-selectin glycoprotein ligand-1. CLA^+ memory T cells preferentially express CCR4, and inflamed dermal blood vessels express one of its ligands, CCL17. Together CLA, CCR4 and CCL17 may contribute to specific memory T cells trafficking to inflamed skin (Fitzhugh et al, 2000), (Sallusto et al, 2000), (Reiss et al, 2001), (Kunkel et al, 2002). In addition to its extravasation role through cutaneous vessels, CCR4 may also drive migration within other tissue types, for example lung and liver, where CCL17 is produced. CCL17, expressed by cutaneous although not intestinal endothelium,

induces integrin-dependent firm adhesion of CLA^+ T cells, consistent with its role in the extravasation process.

B cells

Chemokine expression determines the fate of developing B cell populations and directs their maturation in the bone marrow to the periphery (Bowman et al, 2000). CXCR4 has a role in B cell lymphopoiesis (Sallusto et al, 2000). CXCR5 is a selective and efficacious chemoattractant for circulating naïve B lymphocytes (Carlsen et al, 2002). CXCL12 is expressed constitutively in bone marrow-derived stromal cells and promotes proliferation of B progenitors (Sallusto et al, 2000).

T and B cell interaction in lymph nodes

Interaction between T and B cells is vital for immunological effect. Fluorescent labelling has demonstrated that upon stimulation the cells move from their designated areas to the boundary zone between the T and B zones, allowing immunological co-operation between these cells. A switch in chemokine receptor expression is likely to be the controlling migratory factor. The CXCR5 +ve T cells that localise to B cell follicles are functionally described as 'follicular B helper T cells', as they are required for efficient B cell help within the lymphoid follicle (Carlsen et al, 2002). Antigen-stimulated T cells down regulate CCR7 and upregulate the B cell area receptors CXCR5 and CCR4, thus move towards the B zone. The reciprocal changes occur in the B zone, with increased expression of CCR7 by antigen-engaged B cells, which is the receptor for the T-zone chemokines CCL19 and CCL21. This facilitates B cells migrate towards the T-zone (Reif et al, 2002), (Sallusto et al, 2000).

NK cells

NK cells participate in innate and adaptive immune responses to obligate pathogens and malignant tumours. Activated NK cells produce XCL1, CCL1, CCL3, CCL4, CCL5, CCL22 and CXCL8 (Robertson, 2002). CCL3, CCL4 and CCL5 from NK cells can inhibit *in vitro* replication of HIV. The numbers of NK cells are increased in CD, unlike in UC (Van Tol et al, 1992).

Neutrophils

Neutrophils are an important constituent of innate immunity, with their series of effector functions. They are extremely motile and migrate through tissues with relative ease (Zhelev et al, 2002). In addition to their defensive functions, neutrophils secrete a number of cytokines including CCL4, CCL14, CCL19, CCL20, CXCL1, CXCL8, CXCL9, CXCL10, and CXCL11 (Scapini et al, 2001). In addition, neutrophils can be induced by cytokines to express CCR6 and migrate in response to CCL20 (Schutyser et al, 2000). CCL19 and CCL20 production is induced by either LPS or TNF-α (Scapini et al, 2001). CXCL8 leads to neutrophil recruitment (Murphy, 1997), (Carlsen et al, 2002). Neutrophilic infiltration and accumulation is a prominent feature in the local inflammatory response in UC (Carlson et al, 2002). Like T lymphocytes, neutrophils roll along HEV walls during inflammation. Neutrophil activation is required to generate $\beta 2$ integrin bonds with the endothelium that stop their progression. Unlike naïve T cells, neutrophils are not only activated by ligation of G-protein coupled receptors with chemokines and other

chemoattractants but also receive signals from engagement of adhesion molecules including the selectins and β2 integrins (Ley, 2002).

Macrophages

Macrophages are important in the host's immunological and inflammatory responses. There are numerous macrophages in the normal intestinal mucosa, where they represent the major antigen presenting cells, capable of determining the type of T cell responses that develop in response to luminal antigens. The population of these cells is increased in IBD, and they are phenotypically different from those found in normal intestine, which cannot be easily induced to mediate acute inflammatory responses. Macrophages play a role in mediating the chronic mucosal inflammation, secreting IL-1, IL-6, IL-8, IL-12, IL-18, and TNF-β, which are important in the inflammatory responses in IBD. They also release metabolites of oxygen and nitrogen and proteases that degrade the extracellular matrix. Finally, macrophages appear to be important during resolution of inflammation and repair of the intestinal mucosa that occurs during disease remission (Mahida, 2000), (Murch, 1998).

Eosinophils

Eosinophils may be functionally involved in the pathophysiology of IBD, although data is lacking. CCL11 is a potent chemokine with selective chemotactic activity for eosinophils (Sullivan et al, 1999). CCL20 is also chemotactic to eosinophils. The levels of expression are higher in IBD, particularly CD, negatively correlating with peripheral eosinophil count (Mir et al, 2002). CCL5, CCL7, CCL12 and CCL22 are associated with eosinophil recruitment to the lung, and neutralisation of these chemokines modulates T lymphocyte recruitment (Homey et al, 1999). Chemokine receptor usage by eosinophils is a key area of research in diseases such as asthma, in which eosinophils are selectively recruited to the inflammatory site with associated degranulation. CCR3 is important for eosinophilic response, so is another potential target for therapeutic antagonism (Heath et al, 1997), (Xanthou et al, 2003). Receptor antagonists may prevent eosinophil entry and degranulation and rat monoclonal antibodies specific for CCR3 have been developed (Heath et al, 1997), (Grimaldi et al, 1999).

Mast cells

Mast cells are important as sentinel cells in host defence against bacterial infection (Lin et al, 2003). Although they are potent producers of many biologic active mediators, such as cytokines and chemokines, their precise biologic functions remain undefined. Most of their effectiveness is thought to depend on the recruitment of other immune cells, for example by production of inflammatory mediators such as histamine, proteinases, arachidonic acid metabolites and cytokines (Lin et al, 2003), (Ruschpler et al, 2003). They are thought to be involved in the induction and maintenance of a variety of severe allergic and autoimmune diseases (Stassen et al, 2002). Their relevance in IBD is unclear.

Basophils

CC chemokines receptors are present on basophils and have been implicated in the pathogenesis of IBD and a number of allergic inflammatory dermatitis (Power et al, 1995).

Platelets

In addition to their homeostatic mechanisms, platelets are also involved in protection against pathogens by means of phagocytosis. Furthermore, activation of platelets leads to release of CCCL3, CCL5, CCL7, CCL17, CXCL1, CXCL5 and CXCL8, which attract leukocytes and other platelets (Gear et al, 2003). CXCL12, CCL17 and CCL22 are rapid activators of platelet aggregation and adhesion after their binding to platelet CXCR4 and CCR4. CXCL12 is primarily secreted by endothelial cells. CCL17 and CCL22 are secreted by macrophages and monocytes.

1.6 Chemokines in disease

Aberrant expression of chemokines and their receptors play causative roles in the pathophysiology of numerous inflammatory and autoimmune diseases including multiple sclerosis (MS), rheumatoid arthritis, atherosclerosis, asthma and organ transplant rejection (Horuk, 2001), (Ajuebor et al, 2002)[2], (Rajarathnam 2002). In these diseases, a differential pattern of chemokine induction is observed.

Rheumatoid arthritis

Experimentally, mouse models for rheumatoid arthritis administered with CCR1/CCR2/CCR5 receptor antagonists or CCL5/CXCL8 antibodies exhibit reduced swelling, tissue destruction and pannus formation. CXCR2 knockout studies in mice are associated with lower levels of neutrophil infiltration (Ajuebor et al, 2002)[2].

Multiple sclerosis

Chemokines and matrix metalloproteinases play key roles in leukocyte migration across the blood-brain barrier in infectious and inflammatory diseases. The pattern of chemokine receptor expression patterns reflects disease activity and stage in MS (Sellebjerg et al, 2003). Chemokine research in MS has been focused on animal models with targeted gene deletion exhibiting autoimmune encephalomyelitis. Mice lacking CCR1 or CCR2 are protected from this disease. Administration of antibodies to CXCL10 to such mice with this pathology causes improvement (Ajubor et al, 2002)[1].

Atopic dermatitis

The CCL11/CCR3 ligand/receptor interaction is thought to relate to tissue damage in the initial phase of atopic dermatitis. CCR3 antagonists may be effective therapeutically, and may be utilised for an 'atopy patch test' (Homey et al, 1999).

Helicobacter pylori infection

Helicobacter pylori-mediated gastritis is associated with increased expression of CXCL5, CXCL8, CXCL10 and CXCL13. Ulceration is associated with increased expression of CXCL8 and CCL3. Eradication of *Helicobacter pylori* causes a reduction of chemokine levels (Ajuebor et al, 2002)[1].

Hepatic disease

Hepatic and serum levels of the neutrophil chemoattractant CXCL8 are increased in hepatitis. Hepatic CCL2, CCL7 and CCL8 are elevated in primary biliary cirrhosis and fulminant hepatic

failure. There are increased levels of CXCL9 and 10 in chronic hepatitis C, which are thought to be chemoattractants for T lymphocytes. The use of neutralising antibodies in animal models has demonstrated that CCL3 and CCL5 contribute to T cell recruitment and hepatic injury during T cell recruitment and hepatic injury during graft versus host disease. CXCR2 and CXCL2 have a hepato-protective effect, enhancing liver regeneration (Ajuebor et al, 2002)[1].

CCR6 is over expressed in small liver metastases of colon, thyroid and ovarian carcinomas compared to normal liver. As human liver constitutively expresses CCL20, it may select $CCR6^{+}$ cancer cells. Chemotaxis is thought to be crucial to the formation of liver metastases via up regulation of MMP-9, and inhibition of CCR6 may therefore be effective in prevention (Dellacasagrande et al, 2003), (Campbell et al, 2003).

HIV

Chemokine receptors are necessary for HIV infection and are potential therapeutic targets for treatment (Proudfoot et al, 2002). CCR5 and CXCR4 are the major co-receptors for macrophage tropic and T-cell line tropic viral isolates respectively (Hieshima et al, 2002). Patients lacking CCR5 are resistant to HIV infection (Proudfoot et al, 2002).

Neural disease

Chemokines and their receptors are constitutively expressed in the central nervous system (CNS) by many cell types including neurons and glial cells. In addition to their involvement in neuroinflammation, they are involved in neurodevelopment, and neurophysiologial signalling (Bajetto et al, 2002), (Cho et al, 2002), (Ragozzino, 2002).

Sarcoidosis

CCL19 is implicated in T lymphocyte recruitment in sarcoidodis. It is associated with disease progression and is down-regulated following treatment (Gibejova et al, 2003).

Coeliac disease

In coeliac disease, large numbers of $CCR9^{+}$ lymphocytes are recruited to the small intestinal mucosa, but not to the colonic mucosa, reflecting small bowel regional expression of CCL25 by small bowel enterocytes (Kunkel et al, 2000).

IBD

Chemokines have been implicated in the pathogenesis of IBD (Papadakis, 2004). There is increased expression of the neutrophil attracting CXC chemokines CXCL5 and CXCL8, and the CC chemokines CCL2 and CCL5 in IBD (Ajuebor et al, 2002)[1], (Dwinell et al, 2003). CXCL8 has been identified in infiltrating mononuclear cells, macrophages and neutrophils, whereas CXCL5 co-localises to the intestinal epithelial cells of these patients. CCL2 mRNA protein has been localised to macrophages, smooth muscle cells and endothelial cells, CCL5 mRNA in intraepithelial lymphocytes and in the sub epithelial lamina propria and CCL7 mRNA is found in epithelial cells. Immunohistochemical analysis indicates high intestinal levels of the chemokine receptors CXCR3, CXCR4, CCR3 and CCR5 in CD (Scheerens et al, 2001). Increased

enterocyte CCL20 production has been demonstrated in IBD, which may play an important role in lymphocytic recruitment to and activation in the colonic epithelium in IBD (Kwon et al, 2002).

1.7 CCL20/CCR6/β defensin

The CCR6/CCL20 chemokine receptor/ligand pair is an important constituent of mucosal and epidermal immunity. CCR6 receptor has only two cognate ligands: CCL20 (a CC chemokine) and β-defensin, contrasting with the other promiscuous chemokine receptors that bind multiple ligands (Baba et al, 1997), (Perez-Canadillas et al, 2001).

Structure

Nuclear magnetic resonance spectroscopy has demonstrated that CCL20 exhibits the same monomeric structure as the other chemokines: a three-stranded β-sheet and an overlying α-helix. The monomeric structure of CCR6 includes a disulphide bond between the first and second extracellular loops that confines a helical bundle together with the N-terminus adjacent to the third extracellular loop, creating the structural organisation critical for ligand binding and, therefore, receptor signalling (Ai et al, 2002). Receptor selectivity probably arises from the rigid conformation of the N-terminal dicyclohexylcarbodimide motif as well as the groove between the N-loop and the β2β3 hairpin, which is significantly narrower in CCL20 than in other chemokines (Perez-Candillas et al, 2001).

Gene location

The gene coding CCL20 is located at 2q33-q37 unlike the locus for other chemokine genes at 17q11.2. The gene for CCR6 is located on chromosome 6q27, unlike all the other mapped β-chemokine receptor genes that are clustered on 3p21.3 (Samson et al, 1996), (Siveke et al, 1998).

Location/cellular expression and function

CCL20 is a potent chemokine whose major function is to stimulate CCR6 expressing chemoattractant cells (Dieu-Nosjean et al, 2000). Both CCL20 and CCR6 are highly expressed in the gastrointestinal epithelium, liver, lung and tonsillar crypts (at the site of antigen entry). This chemokine/receptor pair has a particularly important role at skin and mucosal surfaces both in health and inflammation (Schutyser et al, 2003).

At a cellular level, CCL20 is produced by activated monocytes, endothelial cells, dendritic cells, fibroblasts and T cells. CCR6 is expressed by immature dendritic cells and almost all memory T cells that express α4β7 characteristic of mucosal homing and most mature, naïve and memory B cells capable of responding to antigen challenge, NK cells, Langerhan's cells (LC) (Liao et al, 1999), (Nakayama et al, 2001), (Ebert et al, 2002), (Schutyser et al, 2003). Naïve T cells do not express CCR6; this is acquired during activation (Cook et al, 2000). Both CCR6 and CCL20 efficiently attract B cells particularly IgD-memory B cells (Krzysiek et al, 2000), (Liao et al, 2002). CCR6 expression is down regulated after B cell antigen receptor triggering and remains absent during differentiation into Ig-secreting plasma cells, whereas it is reacquired at the stage of post-germinal centre memory B cells. Therefore, within the B-cell compartment, the expression of CCR6 is restricted to functionally mature cells capable of responding to antigen challenge. This

is consistent with a role in antigen-driven B cell differentiation and B-lineage maturation (Krzysiek et al, 2000).

Within the gastrointestinal tract, this chemokine/receptor pair is particularly located in Peyer's patches, where CCL20 induces local migration of dendritic cell subsets expressing CCR6 (Dieu et al, 1998), (Tanaka et al, 1999), (Iwasaki et al, 2000). Gene expression studies have confirmed that CCR6 and CCL20 are expressed in separate but adjacent cell populations within Peyer's patches. The interaction between CCL20 and CCR6 is also critical factor in the ability of memory T cells to firmly adhere to ICAM-1 on endothelial cells; a prerequisite for extravasation (Ebert et al, 2002). This chemokine-ligand pair is therefore important for antigen presentation and for the development of a host adaptive immune response (Liao et al, 1999), (Homey et al, 2000).

The regulation and expression of CCL20 is part of the epidermal and epithelial immune armamentarium to external assault, with up regulation in response to barrier disruption such as occurs in inflammatory disorders (Cook et al, 2000). This chemokine/receptor pair is part of host defence to counteract potential antigenic invasion (Homey et al, 2000), (Schmuth et al, 2002). The constitutive and regulated expression of CCL20 by epithelium is consistent with a role for CCL20 in mucosal adaptive immune response within the gastrointestinal tract (Izadpanah et al, 2001). In mouse knockout studies the absence of CCR6 results in less severe intestinal pathology in animals with chemical induced colitis (Varona et al, 2003). In addition, low basal levels of CCL20 have been detected in dermal blood vessels and epidermis of non-inflamed skin (Charbonnier et al, 1999), which may enhance T cell recruitment to the skin and epidermis for immune surveillance under non-inflammatory conditions (Fitzhugh et al, 2000).

Amongst all chemokines tested, CCL20 appears to be the most potent chemokine inducing the migration of LC and their precursors, which represent a unique population of dendritic cells colonising the epithelium (Dieu-Nosjean et al, 2000). This suggests that CCL20 plays a key role in the control of LC recruitment to inflamed epithelial surfaces and in the regulation of epithelial immunity. In response to inflammatory stimuli, intestinal cells also develop the capacity to chemo attract dendritic cells and memory T cells in close proximity to the single layer of intestinal epithelium that separates the intestinal lumen from the host's internal milieu via CCR6 receptor expression (Izadpanah et al, 2001), (Kaser et al, 2004).

After binding of CCL20 to dendritic cells, the expression of CCR6 is down regulated and CCR7 is up regulated. The up regulation of CCR7 causes dendritic cell migration to the lymph nodes in response to a CCL19/CCL21 chemokine gradient, where these cells present antigen to $CD8^+$ T cells (Olson et al, 2002)[2], (Muller et al, 2003). Thus, CCL20 can bridge the innate and adaptive immune response. Mouse knockout studies have also demonstrated that CCR6 is required for the localisation of immature dendritic cells to the sub-epithelial zone, although is not required for development of any major leukocyte populations, including dendritic cells. Mice with targeted disruption of CCR6 demonstrate deficiencies in Peyer's patch organogenesis (Cook et al, 2000). These mice show impairment of mucosal responses to both oral antigen and enteric pathogens, and additionally demonstrated cutaneous hypersensitivity reactions, while maintaining normal

systemic responses. There are altered responses in contact and delayed-type hypersensitivity models of inflammation. $CCR6^{-/-}$ mice developed more severe inflammation than wild-type animals with 2,4-dinitrofluorbenzene-induced contact hypersensitivity. Conversely, delayed-type hypersensitivity is absent (Varona et al, 2001). These studies indicate a defect in the activation/or migration of the $CD4^{+}$T-cell subsets that down-regulate or elicit the inflammation responses, respectively. Mice knockout studies have also demonstrated that CCR6 is required for normal allergen-induced eosinophil accumulation and for production of IL-5 and IgE (Cook et al, 2000), (Lukacs et al, 2001), (Varona et al, 2001).

CCL20, like many other chemokine, has antimicrobial effects on a wide variety of pathogens. This is probably related to a topological formation of a large, positively charged electrostatic patch on the surface of the molecule (Yang et al, 2003).

The antimicrobial peptide β-defensin (hBD-2) is a small polypeptide that contributes to host defence, and whose overall amino acid sequence shows homology to CCL20. It is able to recruit dendritic and T cells by interacting with CCR6. There is an up-regulated expression of this by human epithelial cells *in vitro* and *in vivo* in response to pro-inflammatory cytokine stimulation or bacterial infection.

Induction

The induction of CCL20 by TNF-α and/or IL-1β varies according to the cell type. These pro-inflammatory cytokines are released following physical injury or infection. IL-1, TNF or enteric pathogens induce CCL20 expression within 30 minutes, via an NF-κB site upstream of the promoter region (Fujiie et al, 2001), (Izadpanah et al, 2001), (Sugita et al, 2002). *In situ* hybridisation work has demonstrated a strong mucosal epithelial induction by systemic treatment with LPS (Tanaka et al, 1999), (Tohyama et al, 2001). In contrast, synergy between IL-1β and TNF-α is required for CCL20 induction in kidney and skin epithelial cell lines (Dieu-Nosjean et al, 2000), (Nakayama et al, 2001).

Disease

As previously outlined, CCL20/CCR6 are of immunological significance in colitis. There is an up regulation of CCL20 in intestinal and skin inflammation, for example in inflamed crypt epithelium in appendicitis, and epidermal keratinocytes in atopic dermatitis and psoriasis (Nakayama et al, 2001). This implicates CCL20 in such inflammatory processes (Dieu et al, 1998), (Tanaka et al, 1999). Psoriasis is characterised by a marked inflammatory infiltrate and hyperproliferation of keratinocytes, with an up regulation of CCR6 and CCL20 within skin lesions. The infiltrate is composed of T-cells, predominantly of the memory phenotype, neutrophils, lining macrophages, and increased numbers of dendritic cells. Skin-homing CLA^{+} T cells are responsible for the development of the lesions through the activation of keratinocytes in association with a consistent pool of maturing LC concentrated around vessels, further implicating an active role of CCL20 in LC trafficking (Dieu-Nosjean et al, 2000).

Most tumour cell lines of epithelial origin, for example renal and colonic adenocarcinomas, express CCL20. In such malignancies, the alteration that occurs in dendritic cell

development/maturation prevents their T cell stimulatory function, which suggests that tumours of epithelial origin producing CCL20 can attract LC cell precursors and divert their function to escape immune surveillance and reach a state of tolerance (Dieu-Nosjean et al, 2000).

CCL20 produced by peripheral dendritic cells and/or macrophages after necro-inflammatory response leads to the recruitment of activated T cells to the liver. This may be pivotal to the local immune response amplification that occurs in various liver diseases.

There is an increased production of CCL20 in rheumatoid arthritis with the accumulation of CCR6-expressing mononuclear cells in addition to synovial fibroblasts. *In vitro* cultured fibroblasts have also been shown to produce CCL20 in response to IL-1β and TNF-α (Matsui et al, 2001).

1.8 Other chemokines and chemokine receptors

CXCR1, CXCR2, CXCL8

Both CXCR1 and CXCR2 share a high degree of homology (Horuk, 2001). CXCR1 and CXCR2 have several cognate ligands in common, including CXCL1, CXCL6 and CXCL8. In addition, CXCR2 binds CXCL2, CXCL3, CXCL5, CXCL9, CXCL10 and CXCL11 (Horuk et al, 2001), (Schraufstatter et al, 2001). The absence of CXCR2 in knockout mice protects them from septic injury, probably by diminishing inflammatory cell recruitment (Ness et al, 2003). One of the cognate ligands for CXCR1 and CXCR2, CXCL8 is a neutrophil and dendritic cell chemoattractant. Neutrophil chemotaxis is mediated primarily through CXCR1 (Schraufstatter et al, 2001). CXCL8 was the first chemokine to be discovered in 1987 (Ajuebor et al, 2002)[1], (Bajetto et al, 2002). CXCL8 also activates neutrophils to degranulate and cause tissue damage (Dinarello, 2000)[2]. The local expression level of CXCL8 correlates with inflammation in IBD, suggesting that this chemokine may have an important role in mediating the immune response in the gastrointestinal tract (Ajuebor et al, 2002)[1], (Banks et al, 2003). CXCL8 is also produced by neurons, various cancer cells, colonic epithelial cells and endothelial cells (Williams et al, 2000), (Schraufstatter et al, 2001).

There is increased expression of CXCR1 in inflamed compared to non-inflamed areas, with strong up regulation in the mucosal epithelium of morphologically damaged surface epithelium, including in UC (Williams et al, 2000). The increased expression of this receptor probably accounts for the initial inflammatory destructive changes seen in UC, with an epithelial neutrophilic infiltrate. The significance of CXCR2 in the intestinal tract has not been defined (Williams et al, 2000).

The chemokine CXCL1 plays a major role in inflammation, tumourigenesis and wound healing (Dhawan et al, 2002). It is constitutively expressed at high levels during inflammation and progression of melanocytes into malignant melanoma (Nirodi et al, 2001). The CXCL1 gene is controlled by a promoter containing four cis-acting immediately upstream to the NF-κB binding sequence. The nuclear DNA-binding protein poly (ADP-ribose) polymerase (PARP) is thought to be a co-activator of CXCL1 transcription (Nirodi et al, 2001). PARP catalyes the transfer of long, branched ADP-ribose chains to either itself or different classes of target proteins involved in

chromatin decondensation, DNA replication, DNA repair, and gene expression (Nirodi et al, 2001). This proposed role of PARP is supported by findings that 3-aminobanzamide, an inhibitor of PARP-specific ADP-ribosylation, inhibits CXCL1 promoter activity and reduces levels of CXCL1 mRNA in a dose-dependent manner (Nirodi et al, 2001). CXCL1 and CXCL2, like CXCL8 are chemotactic for neutrophils. These chemokines are only expressed by the epithelium following stimulation with pro-inflammatory cytokines or LPS (Ohtsuka et al, 2001).

CCR1

Knockout studies indicate that this is a vital chemokine receptor, crucial to host defense. Research has demonstrated that an altered Th1/Th2 cytokine balance occurs in these mice. CCR1 is also vital in trafficking and proliferation of leukocytes of myeloid progenitor cells, and neutrophil migration in response to CCL3. CCR1 is expressed by monocytes, dendritic cells, eosinophils, and lymphocytes but not in neutrophils unless induced by specific cytokines. (Horuk, 2001).

CCR2

CCR2 is a major regulator of macrophage trafficking, and plays a role in the pathogenesis of MS (Horuk, 2001).

CCR3

CCR3 is primarily expressed by eosinophils, in which it has an important role (Horuk, 2001).

CCR4

CCR4 is a selective marker for Th2 T lymphocytes and is up regulated by T cell receptor activation. It is thought to be involved in the pathogenesis of liver injury (Horuk, 2001).

CCR5

CCR5 is thought to play role in the control of granulocytic lineage proliferation or differentiation. It also functions as a co-receptor for HIV-1, for which it is a major entry point (Horuk, 2001). CCR5 variants have been postulated to influence the inflammatory response (Hull et al, 2003).

CCR7

This chemokine receptor is expressed by Th2 cells, and is thought to have a role in allergic inflammation (Horuk, 2001). It is involved in the organisation of secondary lymphoid tissue and is expressed during chronic inflammation. The two cognate ligands for CCR7 are CCL19 and CCL21. The expression of CCL21 during chronic hepatitis C is implicated in T-lymphocyte recruitment that occurs in this disease, and in the organisation of inflammatory lymphoid tissue. CCL21 is thought to promote fibrogenesis within inflamed areas via activation of CCR7 on hepatic stellate cells (Bonacchi et al, 2003). In the periphery, mature naïve B and T cells utilize CCR7, CXCR5 and CXCR5 to recirculate through specialised microenvironments within the secondary lymphoid tissues. Effector and memory lymphocytes express a variety of adhesion molecules and chemokine receptors that enable functionality within microenvironments and non-lymphoid tissues inaccessible to naïve cells (Campbell et al, 2003).

CCR8

CCR8 is highly expressed in the thymus and spleen, and is hardly detected in the peripheral blood lymphocytes. Its precise biological role is unknown, although its expression in Th2 cells suggests a possible role in allergic inflammation. It is also thought to be of significance in HIV infection (Horuk, 2001).

CCR9

The two cognate ligands for CCR9 are CCL25 (secreted only by small intestinal cells), and MAdCAM-1 (Horuk, 2001). CCR9 is likely to be important in the functionally specialised immune system in different areas of the gastrointestinal tract. It is highly expressed in all $CD4^+$ and $CD8^+$ T lymphocytes in the small intestine, although only a small subset of lymphocytes in the colon is $CCR9^+$ (Kunkel et al, 2002). Lymphocytes from other tissues, including tonsils, lung and skin do not express CCR9. Both immature and mature thymocytes express CCR9, suggesting a role in T cell development in the thymus (Rossi et al, 2000), (Horuk, 2001). Although CCR9 is highly expressed in the thymus, it is minimally expressed in lymph nodes and the spleen.

CCR10

The CCL27/CCR10 pair is thought to play a role in both skin homeostasis and may have a role in the inflammatory response. CCR10 is highly expressed in the small intestine and testis, and at lower levels in other tissues (Horuk, 2001).

CXCR3

CXCR3 is crucial in T cell activation and recruitment, and is implicated in allograph destruction (Horuk, 2001).

CXCR4

CXCR4 is ubiquitously expressed by a wide variety of cell types, including most haematopoietic cells. CXCR4 and the ligand CXCL12 play a central role in the migration of haematopoietic stem cells (Campbell et al, 2003). CXCR4 is also involved in the retention of neutrophils within the bone marrow and in the homing of senescent neutrophils back to the bone marrow. As neutrophils age, the expression of CXCR4 is upregulated (Martin et al, 2003). CXCR4 is also highly expressed on vascular endothelial cells, neurons, microglia and astrocytes. It is involved in the embryological development of neuronal networks in the central nervous system and in blood vessel development in the gastrointestinal tract (Horuk, 2001).

CXCR5

CXCR5 is chemotactic for human B lymphocytes. Deletion of the gene for CXCR5 yields mice with abnormal primary follicles and germinal centre of the spleen and Peyer's patches, reflecting the inability of B lymphocytes to migrate into B cell areas. CXCR5 is also a marker for memory T cells (Horuk, 2001).

1.9 Intestinal immunomodulatory cytokines

Cytokines are regulatory proteins crucial for inter-leukocyte communication, classified according to biological activity (Dinarello, 2000). They are primarily located in the lamina propria and are mainly released from activated T and B lymphocytes and macrophages to stimulate immune effector cells. The pro-inflammatory cytokines include IL1, TNF and IL-6, which are contingent to amplification of immunologic and inflammatory processes, particularly in IBD and rheumatoid arthritis (Elliot et al, 2001), (Panja et al, 1998). Their levels are increased in the serum, biopsy tissue culture, and in isolated lymphocytes from IBD patients with levels predictive for acute relapses (Panja et al, 1998), (Schreiber et al, 1999), (Woywodt et al, 1999). Furthermore, patients in clinical remission who are at high risk of relapse can be identified by an increased capacity of intestinal lamina propria cells to secrete TNF-α and IL-1β (Shreiber et al 1998)[2]. There are some inconsistencies in the TNF data, however as some research has indicated that although concentrations of IL-1β and IL-6 correlate with inflammation in biopsy cultures, levels of TNF do not (Reimund et al, 1996).

Contra-inflammatory cytokines such as IL-4, IL-10 and IL-13 suppress genes for pro-inflammatory cytokines and chemokines, thereby balancing the pro-inflammatory responses to limit inflammation (Schreiber, 1998), (Dinarello, 2000). This balance is altered in IBD.

IL-1

IL-1 plays a key role in inflammation, signaling via transcription factors such as NF-κB (Bocker et al, 2000). IL-1 is produced early in inflammation, and induces the production of many other cytokines, amplifying their pro-inflammatory action (Cominelli et al, 1990). Tissue levels of IL-1 have been found to correlate with the degree of tissue inflammation. IL-1β levels are increased in colonic circular muscles of patients with UC, which may contribute to motor dysfunction (Vrees et al, 2002).

There is an evidence that IL-1β gene polymorphisms participate in the determination of the severity and course of IBD although data are not consistently confirmatory (Hacker et al, 1997), (Nemetz et al, 1999), (Mwantembe et al, 2001).

There are two forms of IL-1: IL-1α and β. Both are potent cytokines whose biological activities are indistinguishable (Dinarello, 1997). IL-1α and IL-1β bind to the same IL-1 receptor on various cell types, even though they are distantly related at the primary sequence level (Benjamin et al, 1990). Differential expression varies at a cellular level, for example IL-1β is produced by epithelial cells.

The pro-inflammatory potential of IL-1 is tightly controlled by endogenous inhibitors such as IL-1 receptor antagonist (IL-1ra), and soluble IL-1 receptors to prevent an acute or chronic overproduction of pro-inflammatory cytokines, leading to fatal consequences, as seen in septic shock. IL-1ra has specific purely antagonistic properties against IL-1 receptors, acting as an anti-inflammatory cytokine without causing signal transduction (Cominelli et al, 1997). In IBD, plasma IL-1ra levels correlate with disease activity in addition to laboratory parameters such as C-reactive protein and leukocyte count (Kuboyama, 1998). Measurement of IL-1ra levels may

be used as an indicator of disease activity (Propst et al, 1995). Mice deficient in IL-1ra develop spontaneous rheumatoid arthritis and lethal arteritis, with reduction in disease severity with administration of IL-1ra. A mucosal imbalance between IL-1 and IL-1ra has been proposed as a potential key immunopathology in IBD (Andus et al, 1997), (Dionne et al, 1998), (Stokkers et al, 1998). Study of animal models of intestinal inflammation has indicated that tissue IL-1ra:IL-1 ratio closely correlate with inflammation (Cominelli et al, 1996). One study indicated a slight association of IL-1ra polymorphism with UC, although other studies have not confirmed this (Hacker et al, 1998), (Carter et al, 2001).

Platelets express surface receptors for IL-1 and IL-18, which are significantly increased in IBD. This is thought to relate to the platelet aggregation in IBD, possibly implicating the functional importance of platelets in inflammation (Schaufelberger et al, 1994).

TNF-α

Monocytes, macrophages and T cells produce TNF-α. It can effect the proliferation, differentiation and function of virtually every cell type (Baert et al, 1999). In addition, TNF-α stimulates IL-1 and IL-6 production, expression of adhesion molecules, pro-coagulant activity, endothelial activation and fibroblast proliferation (Baert et al, 1999). Biological effects include cachexia, shock, cytotoxicity and a stimulation of the acute phase response (Baert et al, 1999). It has multiple effector functions, including induction of neutrophil accumulation, granuloma formation, up regulation of adhesion molecules on endothelial cells, pro-coagulant effects and induction of increased intestinal permeability. TNF-α is considered to be centrally involved in the inflammatory process that occurs in IBD in particular CD, as it is a typical Th1 cytokine (Baert et al, 1999), (Shreiber et al, 1999). Serum and stool TNF-α levels correlate with inflammation in patients with active CD (Baert et al, 1999). Blockade of TNF-α has prevented granuloma formation *in vitro* (Baert et al, 1999). There are two TNF receptors, TNFR1 and TNFR2. TNFR1 mediates the majority of biological activities (Sugita et al, 2002).

IL-4

IL-4 is a T-cell derived anti-inflammatory cytokine that inhibits IL-1β and TNF-α production *in vitro* by human monocytes. It also induces IL-1ra. However, there is also evidence that a down-regulation may be beneficial in inflammation (Baert et al, 1999).

IL-10

This anti-inflammatory cytokine inhibits various cell types, including macrophages and dendritic cells (Boone et al, 2003). It down-regulates cytokine production, for example it has a direct inhibitory effect on T cell production of IL-2 and TNF-α (Macdonald et al, 1999). IL-10 also has a major role in the regulatory balance of cytokines controlling mucosal tolerance (Braat et al, 2003). The mechanism of IL-10 inflammatory inhibition is poorly understood. It binds to a recently described receptor IL-10 that is composed of and α and β subunits (Boone et al, 2003).

A relative IL-10 deficiency in patients with UC is thought to contribute to persistent inflammatory changes (Ishizuka et al, 2001). *In vitro* data from cultured epithelial and blood mononuclear cells from patients with active IBD have demonstrated that IL-10 causes an inhibition of IL-1β and

TNF-α, and augmentation of IL-1ra production. Conversely, neutralisation of endogenous IL-10 enhances both TNF-α and IL-1β production and inhibits IL-1ra production, so the administration of IL-10 may be useful therapeutically (Shirachi, 1998). Animal mouse models have demonstrated that topical enema application of IL-10 induces a down-regulation of pro-inflammatory cytokines systemically and locally (Schreiber et al, 1995). Results from clinical trials have so far have been disappointing, although this may relate to the lack of effective mucosal delivery (Braat et al, 2003).

IL-6

IL-6 is a multifunctional pro-inflammatory cytokine that regulates the immune response, haematopoiesis, the acute phase response, and inflammation (Hirano, 1998), (Ishihara et al, 2002)[1]. It has a crucial role in wound healing, probably by regulating leukocytic infiltration, angiogenesis and collagen accumulation (Lin et al, 2003). When its activity as a pro-inflammatory cytokine persists, the acute inflammation becomes chronic, with inflammatory cell infiltration leading to further IL-6 production. It is thought to play an important role in IBD via activation of NF-κB in the intestinal epithelium (Wang et al, 2003). Serum IL-6 concentrations are higher in patients with CD than in UC and healthy controls, with levels correlating with the inflammatory activity (Ishihara et al, 2002)[1]. High levels are associated with a high frequency of relapse, and over expression of IL-6 may be pathogenic in IBD (Jones et al, 1993), (Jones et al, 1994), (Van Kemseke et al, 2000), (Ishihara et al, 2002)[2].

Trans signalling is thought to contribute to chronic intestinal inflammation, whereby IL-6 binds to cells lacking its receptor by formation of a complex with the soluble IL-1 receptor, which can activate T cells. This is a further potential target for antibody development for therapeutic application (Atreya et al, 2000).

IL-2

IL-2 is vital in modulating the immune response. It is an essential T cell growth factor required for division of antigen-activated T cells. IL-1 induces IL-2 receptors. Patients with CD have increased expression of IL-2 receptors in the blood (Choy et al, 1990).

IL-12

IL-12 is involved in the regulation, differentiation and activation of helper T cells, and is pivotal in a Th1 response (Sandborn et al, 2002).

IL-17

IL-17 is a T cell-specific cytokine released by Th1 and Th2 subsets of $CD4^+$ cells, and is a potent mediator of inflammatory responses. Receptors for IL-17 are widely distributed on various cell types (Hata et al, 2002).

IL-18

IL-18 induces IFN-γ production and Th1 responses (Dinarello, 2000)[1]. It mainly exists in activated macrophages and epithelial cells, and shares biological activity with IL-12 (Sandborn et

al, 2002). The IL-18 precursor must be activated by IL-1 converting enzyme (ICE, caspase-1) to yield the active cytokine (Siegmund, 2002). IL-18 is up-regulated in intestinal mucosal cells of patients with IBD (Sandborn et al, 2002). It is neutralised by IL-18 binding protein, which is a naturally occurring secreted protein. This may be a suitable target for therapeutic manipulation (Dinarello, 2000)[2]. Neutralisation of IL-18 reduces arthritis, lung injury and IBD in animal models.

TGF-β

The transmembrane protein transforming growth factor β (TGF-β) plays a major role in the epithelial inflammatory response. This cytokine is present on the cell surface and/or as a secreted polypeptide in an inactive form. Following activation by binding to extracellular matrix proteins, it influences gene transcription and translation of formed mRNA. Locally it acts as a pro-inflammatory agent, but systemically it is a potent immunosuppressive. TGF-β also inhibits the uncontrolled proliferation of epithelial, endothelial, and haematopoietic cells. Furthermore it is a growth factor for most epithelial cells, and affects remodelling phases of wound healing by stimulation of extracellular matrix synthesis. It is therefore important in tissue regeneration, remodelling and fibrosis (Marek et al, 2002). It stimulates immature dendritic cells resulting in an increased expression of a number of chemokines and their receptors, including CCR6 plus increased chemotaxis to its ligand. Conversely, there is a down regulation of CCR6 expression by mature dendritic cells, and thus reduction in chemotactic response (Sato et al, 2000). Defects in TGF-β signalling pathways are linked to carcinogenesis, atherogenesis, fibrosis and autoimmunity. An imbalance of biologically active TGF-β is thought to be pathogenic in IBD. Its expression is highest at sites of antigenic stimulation i.e. within the villi not the crypts, thus deprivation of normal TGF-β may increase susceptibility to IBD (Marek et al, 2002).

1.10 Regulation of chemokine production

The NF-κB protein family is a group of inducible transcription factors that regulate key genes important in immunity, inflammation and cellular proliferation (Sugita et al, 2002). Although there are many different cytokines with varying effector responses, NF-κB is the one common transcriptional activator that exists in virtually all cell types, and is viewed as the central mediator of the immune response. It is necessary for an adequate immune response. Target genes include those encoding the IL-1 receptor, IL-2, IL-12 and TNF-α, transcription factors, adhesion molecules, inducible nitric oxide synthase and acute phase proteins (Ghosh et al, 1998), (Neurath et al, 1998), (Hong et al, 2001), (Dijkstra et al, 2002), (Gan et al, 2002), (Li et al, 2002)[1]. Examples of intestinal epithelial cell NF-κB chemokine gene targets include CCL20, CXCL1 and CXCL8 (Izadpanah et al, 2001). NF-κB also functions as a central regulator of stress responses, including physical and oxidative stress and exposure to certain chemicals. Furthermore, it blocks cell apoptosis in several cell types. *In vitro,* IL-10 and steroids down-regulate NF-κB thereby inhibiting its driven transcription control of pro-inflammatory cytokines (Schreiber, 1998)[2].

Binding of NF-κB to specific DNA sequences located in gene promoter regions is crucial for the functional regulation of transcription. Binding sites are located in promoter regions of most pro-inflammatory cytokines (Schreiber, 1998)[2].

NF-κB is central to the epithelial inflammatory response in the gastrointestinal tract following activation with pro-inflammatory cytokines, or to enteric pathogens. It is crucial for the initiation of mucosal innate immune responses via TLRs and CARD15 and subsequent acute mucosal inflammatory responses. CARD15 is activated by components of the bacterial wall and induce activation of NF-κB (Hugot et al, 2003). NF-κB levels are increased in intestinal biopsies of patients with active CD (Schreiber, 1998)[2].

There are five known members of the NF-κB/Rel family: p65 (RelA), c-Rel, RelB, p50 (NF-κB1) and p52 (NF-κB2). NF-κB subunits are able to homo-/heterodimerize through the Rel homology domain, forming transcription factor complexes with a wide range of DNA-binding and activation potentials (Ashburner et al, 2001). NF-κB dimers containing p65 have the most profound pro-inflammatory activity. For example, p65 over expression increases CCL20 mRNA both directly and via a reduction in TNF (Sugita et al, 2002). p50 is either inactive or involved in blocking NF-κB sites against p65 dimers (Schreiber, 1998)[2].

NF-κB exists in the cytoplasm of mononuclear phagocytes in an inactive form, bound to the inhibitor IκB. This inhibitor is one of the NF-κB regulators (Ashburner et al, 2001). Activation requires the activity of Iκκ, a kinase complex that contains two catalytic subunits, Iκκα and Iκκβ, and a regulatory subunit Iκκ-γ. Activating stimuli including inflammatory cytokines, bacterial LPS, viruses, oxidative stress, UV light and a variety of mitogens leads to phosphorylation of IκB by Iκκ, with rapid proteolytic dissociation of the complex (Schreiber, 1998)[2], (Ashburner, 2001), (Hong, 2001), (Dijkstra et al, 2002). NF-κB is finally activated by further phosphorylation of p65, RelB and c-Rel (Li et al 2002)[1]. The cleaved, phosphorylated NF-κB translocates to the nucleus where it up regulates transcription of specific genes. NF-κB activity does therefore not require *de novo* protein synthesis, so rapid signal transduction is possible (Ghosh et al, 1998). In some tumours, there is constitutive activation of the kinases that modulate IκB kinase (Iκκ), leading to constitutive activation NF-κB with dysregulation of transcription genes coding for cytokines, chemokines, adhesion factors and inhibitors of apoptosis (Richmond, 2002).

The interaction between the p65 subunit and histone deacetylase co repressor proteins 1 and 2 constitutes another means of NF-κB regulation (Ashburner et al, 2001). Acetylation of the histone tails induces transcription through chromatin remodelling, with decondensation of the chromatin in the region of the promoters. Such disruption of the core particle is a prerequisite for transcription. Histone deacetylation, stimulated by IL-1β, reduces transcription, and thus represses NF-κB-regulated genes (Asburner et al, 2001). The activity of histone deacetylase co-repressor proteins is reduced by trichostatin A (TSA), which subsequently increases histone acetylation and TNF-α induced CXCL8 expression (Fusunyan et al, 1999). Like TSA, butyrate modifies the chromatin structure through inhibition of histone deacetylation thereby reversibly altering gene and chemokine expression (Pender et al, 2000).

A further regulator of transcription is poly (ADP-ribose) polymerase (PARP), a nuclear DNA binding protein, which may be involved in promoter specific transcription of chemokines. PARP causes an enhancement of NF-κB-mediated transcription (Virag et al, 2002). It functions as a DNA nick-sensor enzyme. Following binding to DNA breaks, activated PARP cleaves NAD^+ into ADP-ribose and nicotinamide. It polymerises ADP-ribose, catalysing the transfer of long branched ADP-ribose chains to itself or different classes of target proteins involved in chromatin decondensation, DNA replication, DNA repair and gene expression, including histones, transcription factors and PARP itself. Poly(ADP-ribosylation) contributes to DNA repair and to the maintenance of genomic stability. However, oxidative stress causes over activation of this polymerase, with consumption of NAD^+ and consequently ATP, leading to cell dysfunction or necrosis. PARP is activated during early stages of apoptosis in many cell types (Shiokawa et al, 1997). This cellular suicide mechanism has been implicated in many disease processes, and may well be important in the pathogenesis of IBD (Shiokawa et al, 1997), (Nirodi et al, 2001), (Virag et al, 2002). 3-aminobenzamide acts as an inhibitor of PARP-specific ADP-ribosylation, and inhibits CXCL1 promoter activity and reduces levels of CXCL1 mRNA (Shiokawa et al, 1997), (Nirodi et al, 2001).

1.11 Molecular targeting in IBD

Progress in the development of new therapeutic agents has been relatively slow over the last decade. The only biologic compounds of proven efficacy in CD are monoclonal antibodies to TNF (infliximab and CDP571), and to the leukocyte adhesion molecule α4 integrin (natalizumab) (Sandborn et al, 2002)[1]. However, many novel targets have been identified for potential therapeutic manipulation in IBD, and consequently several significant trials should emerge in the coming years.

Pro-inflammatory cytokines

Theoretically, blockade of the pro-inflammatory cytokines IL-1, IL-6, IL-8, TNF-α, IL-12 may be of therapeutic benefit. Reducing the biological activities of IL-1 and TNF has been attempted by several different, but highly specific strategies, which involve neutralising antibodies, soluble receptors, receptor antagonism, and inhibition of proteases that convert inactive precursors to active, mature molecules. The anti-TNF agent infliximab is a humanised chimeric monoclonal antibody of the IgG1 subclass (Zboril, 2002). This was shown to be effective in at least two thirds of patients with steroid-dependent chronic active CD, reducing the clinical signs, symptoms and histological disease activity (Baert et al, 1999). Additional benefit of this drug may be derived from the associated reduction in other pro-inflammatory mediators such as IL-6. Within 6 hours of infliximab therapy, IL-6 levels are normalised, with reduced levels of cytokine inhibitors such as soluble p75, p55 and IL-1ra (Charles et al, 1999). The use of infliximab as a therapeutic agent has been limited by toxicity for example acute and delayed sensitivity reactions following formation of human anti-chimeric antibodies (D'Haens et al, 2001), (Bauditz et al, 2002). The fully humanised CDP571 genetically engineered IgG4 monoclonal TNF-α antibody is less immunogenic. This was constructed by grafting the complementarity-determining region of a mouse anti-human TNF-α monoclonal antibody into a human IgG4

antibody framework. It is thought to be effective by neutralising soluble and transmembrane TNF. It is not effective in unselected patients with active CD and has been withdrawn from development, although it may be effective in patients with elevated C-reactive protein (Sandborn et al, 2003). A further biologic anti-TNF product CDP870 is to be assessed in phase III trials following good results with phase II trials with a good drug safety-profile (Choy et al, 2002), (Rose-John et al, 2003), (Sandborn et al, 2003).

The two cell surface TNF receptors, p55 and p75 constitute a further area of potential therapeutic manipulation. Soluble, truncated versions of these are present in body fluids, consisting only of the extracellular, ligand binding domain. They are thought to be involved in the regulation of TNF-activity (Sandborn et al, 2002). Onercept is a genetically engineered recombinant human TNF-receptor p55 monomer (Sandborn et al, 2002). Initial assessment of this drug indicates it has satisfactory safety and pharmacokinetic characteristics, and may be a suitable TNF-α antagonist for clinical anti-inflammation, although further studies are required to assess effectiveness (Trinchard-Lugan et al, 2001), (Sandborn et al, 2003). Etanercept is a genetically engineered fusion protein consisting of two identical chains of recombinant human p75 monomer fused with the Fc domain of human IgG1 (Sandborn et al, 2002), which is designed to neutralise soluble TNF receptors. Although this is safe, a placebo-controlled study failed to demonstrate any benefit (Sandborn et al, 2003).

Thalidomide is a small molecule that degrades TNF and IL-12 mRNA, thereby inhibiting their synthesis (Sandborn et al, 2002). Initial data has indicated that this is an effective short-term treatment for symptomatic IBD (Bariol et al, 2002). Multi-centre placebo controlled phase II trials are ongoing (Cellgene). Another TNF-blocking small molecule under evaluation is CNI-1493 (Sandborn et al, 2002).

IL-2 receptor antagonists have been used in double blind, placebo-controlled trials. Pilot studies of the IL-2 receptor antibody dacclizumab in refractory UC have demonstrated a benefit, although further evaluation is necessary (Van Assche et al, 2000). The chimeric antibody to IL-2, basiliximab appears to be effective at inducing remission in steroid-resistant UC (Creed et al, 2003).

The therapeutic potential of IL-1ra administration in IBD has been considered. After the cloning of IL-1 in 1990 and subsequent production of recombinant protein, much interest was generated in the use of recombinant IL-1ra as an anti-inflammatory drug. It was shown to reduce inflammation in animal models (Cominelli et al, 1990), and reduce mortality of patients with septic shock in phase II trials. However this benefit was not confirmed by a phase III trial. Therapeutic IL-1 receptor blockade in IBD has not been discounted, and modulation of the IL-1-ra/IL-1 balance may be of therapeutic benefit (Cominelli et al, 1997). The benefit of prednisolone may result from an alteration of this ratio, with a decrease in IL-1 receptor antagonist release (Shigematsu, 1998). One group demonstrated that IL-1 receptor antagonism inhibits IL-1β-augmented IL-1α and TNF-α release by mononuclear cells from patients with IBD (Shigematsu, 1998).

Antibodies to IL-1β, termed CDP-484 are being assessed in pre-clinical trials by Celltech, for potential therapeutic benefit in rheumatoid arthritis. This high affinity PEGylated antibody fragment may well be of clinical benefit in IBD.

The ICE protease cleaves the precursors of IL-1β and IL-18 into active cytokines (Siegmund et al, 2001), (Siegmund, 2002). Several ICE inhibitors are available for experimental use *in vivo* and *in vitro*. Phase I trials of the orally active ICE inhibitor Pralnacasan have demonstrated successful IL-1β inhibition and a good safety profile. Phase II trials are ongoing in rheumatoid arthritis (Siegmund, 2002).

Animal model studies have demonstrated that administration of IL-12 can prevent or reduce intestinal inflammation (Neurath et al, 1995). A phase II dose-finding trial with high affinity antibodies to this cytokine is underway (Sandborn et al, 2002).

Phase II studies are also underway to assess the use of anti-IFN-γ therapy in patients with CD. Animal models have indicated that this to be less effective than anti-IL-12 antibodies (Sandborn et al, 2002). Lidocaine and related local anaesthetics are effective in UC, probably from direct effects on epithelial cells to inhibit the secretion of pro-inflammatory cytokines (Lahav et al, 2002), although clinical trials are needed.

Antibodies to IL-18 have been reproduced, although their benefit in IBD has not yet been assessed (Sandborn et al, 2002).

Anti-inflammatory cytokines

Augmentation of the anti-cytokine IL-10 offers an alternative approach to therapy, with suppression of pro-inflammatory cytokine expression by macrophages, dendritic cells and neutrophils. In addition, it also suppresses enzymes of the cyclooxygenase pathway (Mahler et al, 2002). Several large multicentre trials treating patients with mild/moderate or therapy-refractory CD indicate that although it is was found to be safe and well tolerated, the clinical improvement was not significant (Herfarth et al, 2002). The failure of these trials may have resulted from incorrect dosing, mode of administration, or from usage in the wrong patient cohort or alternatively from the already augmented IL-10 levels in IBD. Further studies are ongoing. Genetic engineering of T cells has been considered as a means to deliver IL-10 as an immunotherapeutic agent (Madsen, 2002). The use of genetically engineered *Lactococcus* bacteria that delivers IL-10 to the colon is currently being assessed (Steidler et al, 2000).

IL-11 is an anti-inflammatory mesenchymally-derived chemokine that has been administered in recombinant form as a weekly subcutaneous dose in mild-moderately active CD. It is safe and clinically effective, although only in an undefined subset. Further trials are required (Sanborn et al, 2002).

Pro-inflammatory signalling

Control of pro-inflammatory signalling molecules, such as NF-κB is a further strategic area of potential targeting in the treatment of IBD (Schreiber, 1998)[2]. Steroid-induced healing of colonic

inflammation is associated with the disappearance of NF-κB from nuclear extracts which is supportive of this strategy (Ardite et al, 1998). Sulphasalazine and mesalamine are non-selective inhibitors of NF-κB (Sandborn et al, 2002). There are no human studies of selective NF-κB inhibitors with IBD (Sandborn et al, 2002). Animal models have demonstrated that p65 anti-sense oligonucleotide blocks NF-κB, but has unproven benefit in IBD. However, *in vitro* studies have demonstrated a reduction in IL-1, IL-6 and TNF production from macrophages extracted from patients with active CD following NF-κB blockade (Neurath et al, 1998). As the level of reactive oxygen species is thought to regulate NF-κB, antioxidants may inhibit phosphorylation of IκB upon TNF stimulation (Li et al, 2002). The therapeutic efficacy of 5-aminosalycilic acid in IBD may be related to its anti-oxidant properties (Simmonds et al, 1999).

Adhesion molecules

Alteration of adhesion molecules such as ICAM-1 is likely to affect lymphocyte trafficking, so they are potential targets for therapeutic benefit. Natalizumab is a recombinant IgG4 humanised monoclonal antibody to the α4 integrin. Phase II trials have indicated that this is well tolerated, and moderately effective in active CD (Gordon et al, 2001), and phase III trials are currently underway. Furthermore, large placebo-controlled, dose finding, trials are ongoing with LDP-02, a recombinant IgG1 humanised monoclonal antibody against α4β7.

Preliminary results have shown that the anti-ICAM antisense oligonucleotide ISIS 2302 (anti-ICAM) is effective in CD refractory to steroids (Heresbach et al, 1999). This is a 20 base phosphorothionate oligodeoxy-nucleotide designed to hybridise to a sequence in the 3' untranslated region of the human ICAM-1 message. The heterodimer formed is enzymatically cleaved, reducing the ICAM-1 expression (Sandborn et al, 2002).

Metalloproteinase enzymes

The development of specific MMP inhibitors could impact the natural history of IBD. In UC and CD, the imbalance between MMPs and TIMP favours degradation and may be significant in the pathogenesis of IBD. Enhanced production of MMP3 correlates well with IL-1β, IL-6, TNF-α and IL-10 (Louis et al, 2000). MMP enzymes are activated by T cells, and are inhibited by IL-10 (Pender et al, 1997). IL-10 therapy could theoretically be of benefit via its effect on MMP enzymes. One inhibitor of MMP is Marimastat, which reduces the gastrointestinal inflammation in animal models though has not been subject to clinical trials (Sykes et al, 1999).

Eicoasanoids

The pathogenic importance of eicoasanoids in IBD is unclear. Mucosal production of prostaglandins, thromboxanes and prostacyclins are elevated in IBD, but research has not clarified their pathogenic role (Rampton et al, 1980), (Ligumsky, et al, 1981), (Gertner et al, 1994).

Animal studies have indicated that suppression of cyclooxygenase-2 can result in exacerbation of inflammation-associated colonic injury (Reuter et al, 1996). However, the use of COX-2 inhibitors has not been adequately assessed in IBD; whether they will prove beneficial is not yet

known (McCartney et al, 1999). Ridogrel, an inhibitor of thomboxane-mediated platelet aggregation has been shown to be of no therapeutic benefit in IBD (Carty et al, 2001).

Others

A phase II trial of a monoclonal antibody to CD40L is underway in patients with CD. This co-stimulatory molecule is induced by antigen recognition of T cells (Sandborn et al, 2002). Studies assessing the benefit of antibodies to the CD4 markers of helper T cells are also ongoing (Sandborn et al, 2002).

Other biologic compounds for which there is insufficient evidence to judge efficacy for IBD include: IF-α, IF-β1a, granulocyte colony stimulating factor, (G-CSF), granulocyte macrophage colony stimulating factor (GM-CSF), epidermal growth factor, keratinocyte growth factor 2 (repifermin), human growth hormone and TGFβ (Sandborn et al, 2002). Following the identification of T-bet in the regulation of T cell-mediated colitis, specific targeting of this pathway may lead to clinical improvement in IBD, and other Th1 T lymphocyte-associated diseases (Neurath et al, 2002).

Heparin is possibly effective in UC (Evans et al, 1997), although this may relate to an as yet undefined immunomodulation rather than anticoagulation effect as warfarin has no clinical impact in IBD (Gaffney et al, 1995).

Chemokines

As chemokines are involved in pathological processes in addition to physiological, their receptors are potential targets for therapeutic intervention. This is likely to alter cellular infiltration and modulate the inflammatory response, which has been accomplished for many years using such drugs as corticosteroids and cyclosporin A (Ina et al, 2002), (Yang et al, 2002). However as these drugs are associated with numerous side effects, more specific less toxic agents are required. The blockade of a single chemokine receptor may theoretically provide the specific targeted therapy required.

There are six broad methods of reducing chemokine receptor stimulation. The first employs the use of monoclonal antibodies against chemokines or their receptors. Such antibodies have already been developed against certain chemokine receptors, and some also have additional receptor antagonistic properties (Heath et al, 1997), (Wu et al, 1997), (Grimaldi et al, 1999), (Onuffer et al, 2002). Neutralising antibodies to CCL3 have been demonstrated to inhibit type 1-hypersensitivity reactions *in vivo* (Ono et al, 2003). CAT231 is a genetically engineered antibody by Cambridge antibody Technology Plc with specificity for CCL11 (Ono et al, 2003).

The second method involves the use of specific receptor antagonists; a strategy used by herpes and pox viruses. The *Molluscum contagiosum* virus expresses an antagonist for several CC and CXC chemokines (Sallusto et al, 2000). Modification of the N-terminus of chemokines generates ligands that are effective antagonists, for example, N-terminal modifications of CCL5 results in powerful inhibitors of CCR5 and other chemokine receptors (Gong et al, 1996), (Simmons et al, 1997), (Mack et al, 1998). Antagonists against multiple rather than single chemokine receptors

may be more effective than inhibitors of specific chemokines for controlling cell migration and inflammation. For example, in one early study the NH2-terminal residues were found to partly determine the receptor specificity of CCL5, and deletions within his region permitted binding to multiple CC chemokine receptors (Gong et al, 1996).

The third method of receptor intervention involves the use of small organic molecules. These have been used to disrupt the ligand-binding to G protein-coupled receptors (Murakami et al, 1997), (Schols et al, 1997), (Onuffer et al, 2002). Chemokines bind their receptors with nanomolar affinity, and successful design of a small molecule antagonist should bind the receptor with an equivalent specificity and affinity (Rajarathnam et al, 2002). Such molecular receptor antagonists have been identified that are selective for CXCR2, CXCR4, CCR1 and CCR5. T22 synthesised peptide blocks CXCR4, inhibiting T cell-tropic HIV-1 entry into target cells (Murakami et al, 1997). There is evidence that inhibition of CCR6 may be effective in the treatment of contact dermatitis, liver disease and allergic pulmonary lung disease (Lukacs et al, 2001), (Shimizu et al, 2001).

The fourth method of receptor intervention involves internalisation of receptor and inhibition of receptor cycling, for example CCR5, the principal co-receptor for M-tropic HIV-1 strains (Mack et al, 1998).

The fifth method incorporates a primary reduction of chemokine expression, for example by use of leflunomide and methotrexate (Ho et al, 2003).

The final method involves the use of gene therapy, which has yet to be explored in IBD. As CXCR2 agonists are beneficial in tissue repair, particularly in hepatic diseases, gene therapy using adenoviral vectors to deliver CXCL2 cDNA to sites of inflammation is now being studied. Early results indicate a reduction in hepatic injury (Bone–Larsen et al, 2000), (Ajuebor et al, 2002)[2].

CXCL8 was one of the first chemokines to be considered as a potential target for therapeutic benefit because of its powerful effects on neutrophilic infiltration. However, the development of an effective agent was hampered by the lack of specificity of its cognate receptors, CXCR1 and CXCR2. These receptors differ in their selectivity for other chemokines as well as in their regulation and signal transduction (Murphy, 1997). A phase II clinical trial of humanised CXCL8 antibody ABX-IL-8 for use in treatment of rheumatoid arthritis is ongoing (Abgenix Inc, California, USA), (Ajuebor et al, 2002)[1].

Chemokines are being studied for their potential usage in promoting the regression or even eradication of tumour mass, by inducing the migration of T cells, NK cells, dendritic cells and/or macrophages. They can act as autocrine and paracrine growth factors, and can induce angiogenesis or angiostasis, regulate metastasis and have a role in the host's immune response against tumour cells. Although many chemokines have anti-tumour activity, including CCL1, CCL2, CCL5, CCL7, CCL16, CXCL9 and CXCL10, chemokines used in isolation seem to have limited anti-tumour efficacy (Rossi et al, 2000). The main current area of research is the usage

of chemokines as chemoattractants (e.g. CCL19, CCL21, CXCL9, CXCL10, CXCL12 and XCL1) combined with cytokines (IL-2, IL-12, and GM-CSF, which stimulate T cell, NK cells or tumour antigen-pulsed dendritic cells (Homey et al, 2002). This approach could be used to reverse inflammatory disorders, with the block of T and NK cellular infiltration combined with blockage of IL-1 or TNF, and may enable lower doses and hence toxic effects of such agents (Homey et al, 2002). They may therefore provide adjuvent benefit.

The different approaches in chemokine receptor manipulation are well illustrated in the treatment of HIV. Chemokine manipulation remains an area to be explored in IBD. However, limited study has been carried out in other diseases. CXCR4 and CCR5 are co-receptors with CD4 and human immunodeficiency virus-type 1 (HIV-1) infection (Simmons et al, 1997). Bicyclams are novel low molecular weight anti-HIV agents shown to be effective as potent and selective CXCR4 antagonists. They are highly potent and selective inhibitors of HIV-1 and HIV-2 replication (Scols et al, 1997). CXCR4 antagonist bicyclam derivatives were assessed in clinical trials and, although effective, were withdrawn from phase II trials in view of cardiac side effects (Scozzafava et al, 2002). Receptor internalisation and inhibition of receptor recycling has been identified as another potential area for therapeutic intervention against HIV infection (Mack et al, 1998). Finally, manipulation of CXCR4 improves stem cell mobilisation and could be useful in future stem cell therapeutic applications (Lapidot et al, 2002).

CCR5 is thought to be an ideal target site for the development of inhibitors to the HIV infection. This receptor is expressed by T cells and macrophages, and functions as the main co-receptor for macrophage (M) - tropic strains of HIV-1. Detailed analysis has revealed that there is a complicated pattern of a HIV-1 envelope glycoprotein gp120 to different regions of CCR5, but a relatively simple pattern for chemokine binding (Wu et al, 1997). Potent CCR5 antagonists from several classes of polycyclic derivatives have been identified. The oxime-piperisine derivative SCH-351125 has progressed to clinical evaluation (Scozzafava et al, 2002).

Blockade of CXCR3 and CCR5 may also be effective in the treatment of chronic autoimmune/inflammatory processes such as rheumatoid arthritis, autoimmune diabetes, chronic transplant rejection and MS (Balashov et al, 1999). Analysis of the expression of these receptors may also be of clinical use in the immunologic staging of multiple sclerosis (Balashov et al, 1999).

1.12 Outline of MD thesis

As chemokines and their receptors are important constituents of gastrointestinal epithelial immunity, study of these important immunological mediators may help to identify targets for the development and use of new therapeutic agents. IBD is an intestinal epithelial disease in an accessible organ that is therefore conducive to treatment.

This MD sets to answer the following questions:

1 Which chemokines and their receptors are likely to be central to the disease processes in IBD?
2 Expression patterns of individual chemokines have been previously investigated, but is there a particular coordinate response to inflammatory stimuli in IBD?
3 What is the effect of pro-inflammatory cytokines on the chemokines identified?
4 What is the potential for therapeutic intervention at a chemokine/chemokine receptor/pro-inflammatory cytokine level in IBD?

In this research, the expression of the entire chemokine family within colonic mucosa from IBD patients was compared to the expression in non-inflamed and inflamed controls. A microarray, representing every member of this superfamily and their cognate receptors, was constructed and hybridised with probes derived from colonoscopic biopsies. While expression levels of individual chemokines and their receptors have been measured in colon tissue previously, no one has attempted to analyse transcription levels of the entire chemokine superfamily in parallel. Advances in gene expression profiling technology enabled construction of a custom chemokine microarray containing all chemokines and receptors. Results were confirmed and extended by real-time quantitative polymerase chain reaction (PCR), immunohistochemistry and flow cytometric analysis of colonic tissue.

Fujiie et al (2001) previously demonstrated that human colon carcinoma cell lines express CCL20, which is up-regulated by either TNF-α or IL-1β depending on lineage. In order to further characterise chemokine expression by epithelial cells, the array was used to profile gene expression from cultured Caco-2 and HT29 cell lines. These colonic cancer epithelial cell lines were chosen for studying expression of chemokines and cytokines, due to the spontaneous differentiation exhibited. In the pre-confluent state these cells are relatively undifferentiated. After a several days post-confluency, these cells develop markers of a differentiated phenotype for absorptive enterocytes including the expression of digestive enzymes, tight junctions, a well-developed brush-border, and a polarised morphology. In the cellular differentiation there are therefore important morphological and functional changes. In this research, the cultured cells were harvested 48 hours post-confluence, when they express a predominantly colonic phenotype (Engle et al, 1998), and cultured with and without combinations of IL-1β, TNF-α and LPS. In order to investigate potential regulatory pathways previously implicated in epithelial CXC chemokine production IL-1β and TNF-α dual stimulations were also performed in the presence of TSA and benzamide in Caco-2 cells to determine any involvement of histone deacetylation and PARP1, respectively (Ashburner et al, 2001), (Nirodi et al, 2001). The

expression of multiple pro-inflammatory cytokines, including CXCL8, is inhibited by spontaneous differentiation of the Caco-2 colon cancer cell line by growth to a post-confluent state.

Enzyme-linked immunosorbent assays (ELISA) were performed on the supernatants of Caco-2 cells to confirm that protein expression is consistent with mRNA expression observed.

Although analysis data from cultured colonic carcinoma cell lines is of value, primary colonic epithelial cell culture provides a more reliable model, with closer approximation to *in vivo* conditions. The epithelium was stripped from surgically removed, normal colonic sections, incubated in varying combinations of IL-1β, TNF-α and LPS, and profiled with the chemokine microarray.

To determine whether non-mucosal epithelial cells expressed the same subset of chemokines as colonic cells in response to pro-inflammatory cytokine stimulation, primary keratinocytes were grown to confluence and stimulated with and without combinations of IL-1β, TNF-α and LPS, and profiled with the chemokine microarray.

The knowledge gained from this research was subsequently utilised to investigate NEC, using immunohistochemical staining. This condition has phenotypic and mechanistic similarities to IBD, making comparative chemokine expression studies highly relevant.

1.13 Microarray technology

Microarray technology represents a major advance in functional genomics, allowing systematic identification of large numbers of genes in parallel (Li et al, 2002)[2]. When applied to clinical samples, this technology allows detailed comparisons and assessments not previously possible. In general, two microarray technologies have been emerged. The first includes deposition of oligonucleotides onto a glass surface. Commercially available oligonucleotide arrays are termed "GeneChip®" (registered trademark by Affymetrix). These arrays are synthesised using photolithographic techniques, and represent up to 40 000 genes. However, the high cost, limited length of oligonucleotide chains (20-80 bases long), and the necessity to know the gene sequences limits its application and accuracy. The second technology incorporates cDNA fragments printed on a glass slide or nylon membrane. cDNA probes are made from RNA transcripts through reverse transcription. During the process, a label is incorporated into the probe which is hybridised to the microarray. In addition to the lower costs, this method provides greater flexibility and enables more highly focused study. Fewer genes are included in this type of array (500-5000 bases long). To overcome the problem of cross hybridisation due to sequence homology, the 3'-untranslated end of the target genes are printed onto the array to reduce the probability of hybridisation being affected by pre-termination of reverse transcriptase. Some short domain sequences present at high frequency in the total cDNA population are included in the hybridisation solution to block potential cross-hybridisation of repetitive sequences (Warner et al, 2002), (Li et al, 2002)[2].

Fluorescence or the use of radio-labelling is used to achieve the detection of hybridised genes in each spot. A digital image of the array is then obtained, which is analysed for the location of

individual spots on the slide, spot boundary and signal intensity compared to background, using pixilation. A quantitative threshold is incorporated to enhance accuracy. Data normalisation allows for differences in quality and quantity of initial RNA. Relative quantification is achieved by determinance of ratio to stably expressed reference 'housekeeping genes'. This is a group of genes coding for proteins whose activities are essential for maintenance of cell function, and whose expression is believed to be uniform (Li et al, 2002)[2]. Mathematical hierarchical clustering groups data points whose branch lengths represent similarities, thus clustering the genes (Orr et al, 2002). The measured data are colour-coded.

Chapter 2

Materials and Methods

2.1 Materials and buffers

2.1.1 Materials

2.1.2 Buffers

2.2 Methods

2.2.1 Patient inclusion, sample collection and preservation

2.2.2 Total cellular RNA preparation, cDNA probe synthesis, microarray hybridisation and analysis

2.2.2.1 Microarray construction

2.2.2.2 Preparation of total cellular RNA from colonic biopsies and RNA assay cultured cell lines

2.2.2.3 RNA quantification

2.2.2.4 cDNA probe synthesis

2.2.2.5 Microarray hybridisation and analysis

2.2.2.6 Real-time quantitative RT-PCR

2.2.3 Histopathological assessment of colonic tissue

2.2.4 Immunohistochemical localisation and quantification of chemokines using immunoperoxidase technique

2.2.4.1 The technique of immunohistochemistry

2.2.4.2 Preparation of sections and pre-treatment methods

2.2.4.3 Primary antibody application

2.2.4.4 Secondary antibody application

2.2.4.5 Application of DAB

2.2.5 Analysis of cell lines

2.2.5.1 Cell propagation

2.2.5.2 Cell count and viability assessment

2.2.5.3 Cell stimulation

2.2.6 Quantitative determination of chemokine protein concentrations in cell culture supernatants

2.2.6.1 The technique of ELISA

2.2.6.2 ELISA procedure

2.2.6.3 Optical densometry

2.2.7 Flow cytometric analysis of colonic biopsies

2.2.8 Stimulation of colonic epithelium in colonic biopsies

2.2.9 Primary colonic epithelial culture and stimulation

2.2.9.1 Epithelial cell separation

2.2.9.2 Epithelial cell propagation

2.2.9.3 Cell count and viability assessment

2.2.9.4 Cell pellet formation

2.2.9.5 RNA extraction

2.2.9.6 Microarray hybridisation and analysis

2.1 Materials and Buffers

2.1.1 Materials

18s and 28s ribosomal RNA standards	Sigma Aldrich Company Ltd, Dorset, UK
L-Glutamine	Sigma Aldrich Company Ltd, Dorset, UK
Sodium hydroxide	Merck, Poole, Dorset, UK
ABC kit for immunohistochemistry	Vector laboratories, Peterborough, UK
Absolute alcohol	Chemix, Wiggan, Lancashire, UK
Acid ethanol	Chemix, Wiggan, Lancashire, UK
Benzamide	Sigma Aldrich Company Ltd, Dorset, UK
Bio-Spin 6 Chromatography Columns	BIO-RAD, Hercules, CA, USA
Biotinylated rabbit anti-goat antibody	Vector laboratories, Peterborough, UK
Bovine foetal calf serum	Sigma Aldrich Company Ltd, Dorset, UK
Caco-2 cells	European Collection of Animal Cell Cultures, Porton Down, UK
Calcium chloride	Merck, Poole, Dorset, UK
Cell dissolution solution/EDTA	Sigma Aldrich Company Ltd, Dorset, UK
Chymotrypsin	Sigma Aldrich Company Ltd, Dorset, UK
α^{33}P-dCTP	NEN, Boston, MA, USA
DAB - 3,3'-diaminobenzidine substrate Kit for peroxidase,	Vector laboratories, Peterborough, UK
Deoxynucleotides (dATP, dGTP and dTTP)	Amersham, UK
DMEM (Dulbecco's modified eagle's medium)	Sigma Aldrich Company Ltd, Dorset, UK
DPX (distyrene, plasticizer, and xylene)	Merck, Poole, Dorset, UK
E.coli lipopolysaccharide	Sigma Aldrich Company Ltd, Dorset, UK
Epilife™medium	Cascade Biologics Inc, Portland, OR
ExpressHyb hybridisation solution	Clontech, Palo Alto, CA, USA
Foetal Calf Serum	Sigma Aldrich Company Ltd, Dorset, UK
L-Glutamine	Sigma Aldrich Company Ltd, Dorset, UK
Hanks buffered salt solution	Sigma Aldrich Company Ltd, Dorset, UK
HT29 cells	European Collection of Animal Cell Cultures, Porton Down, UK
Human Cot-1 DNA	Invitrogen, Paisley, UK
Human keratinocyte growth supplement	HKGS, Cascade Biologics Inc, Portland, OR, USA
Hydrogen peroxide	Sigma Aldrich Company Ltd, Dorset, UK
IL-1β	PeproTech, Rocky Hill, NJ, USA
Marvel milk powder	Tescos, London, UK
McCoy's 5A cell culture medium	Sigma Aldrich Company Ltd, Dorset, UK
Methanol	Merck, Poole, Dorset, UK
Monoclonal anti-human CCR-6 antibody	R and D Systems, Oxon, UK
Monoclonal anti-human CXCR-1 antibody	R and D Systems, Oxon, UK
Monoclonal anti-human CXCR-2 antibody	R and D Systems, Oxon, UK

Monoclonal anti-human CCL20 alpha antibody	R and D systems, Oxon, UK
Normal human primary epidermal keratinocytes	Cascade Biologics Inc , Portland, OR, USA
NCTC medium	Sigma Aldrich Company Ltd, Dorset, UK
Penicillin streptomycin antibiotics	Sigma Aldrich Company Ltd, Dorset, UK
Poly (dA)	Invitrogen, Paisley, UK
Poly (dT)	Invitrogen, Paisley, UK
RNA 6000 Nano Assay kit, used with Agilent 2100 bioanalyser	Agilent Technology, California, USA
RNeasy kit	Qiagen, Crawley, UK
RNA later	Ambion, Austin, Texas, USA
RNeasy Mini Kit (Containing buffers RLT,RW1 and RPE)	Qiagen, Crawley, UK
RPMI medium	Sigma, Poole, Uk
Salmon Testes DNA	Sigma, Poole, UK
Sodium dodecyl sulphate (SDS)	BIO-RAD, Hercules, CA, USA
Sodium bicarbonate	Sigma, Poole, Uk
0.1mmol sodium hydroxide pH 8	Merck, Poole, Dorset, UK
Sodium tetraborax	Merck, Poole, Dorset, UK
SUPER RNaseIn	Ambion, Austin, Texas, USA SuperScript II Invitrogen, Paisley, UK
Superscript II RNase H^- Reverse Transcriptase	Invitrogen, Paisley, UK
Taqman Gold RT-PCR Kit	Applied Biosystems, Warrington, UK
T84 cells	European Collection of Animal Cell Cultures, Porton Down, UK
TNF-α	PeproTech, Rocky Hill, NJ, USA
Trichostatin	Sigma Aldrich Company Ltd, Dorset, UK
Trypsin solution (0.05g trypsin + 0.05g chymotrypsin in 100ml 0.1% calcium chloride pH 7.8)	Sigma Aldrich Company Ltd, Dorset, UK
Trypsin/EDTA	Sigma Aldrich Company Ltd, Dorset, UK
Xylene	Chemix, Wiggan, Lancashire, UK

2.1.2 Buffers

Quanitkine ELISA wash buffer concentrate (20ml wash buffer diluted in 480ml distilled water)
R and D Systems, Oxon, UK

Ethylenediaminetetraacetic acid (EDTA) Merck, Poole, Dorset, UK
(Made just prior to use, 2 litres distilled water, 0.744g EDTA, adjusted to pH 8 with sodium hydroxide, concentration 0.1M)

Phosphate buffered saline (PBS)
Sigma Aldrich Company Ltd, Dorset, UK
(1 tablet dissolved in 200ml distilled water, 0.1M , pH 7.2)

RNA gel loading buffer
Eppendorf, Hamburg, Germany

SSC buffer
BIO-RAD, Hercules, CA, USA
(150mM sodium chloride, 17.5mM sodium citrate, pH 7.0)

Sodium citrate buffer
Merck, Poole, Dorset, UK
(25ml 2M sodium hydroxide, 21g citric acid, 10 litres distilled water, 0.01M, pH 6.0)

Tris buffered saline (TBS)
Merck, Poole, Dorset, UK
(87.5g sodium chloride, 6.6g Tris, 41.5ml 1M hydrochloric acid, pH 7.6)

2.2 Methods

2.2.1 Patient inclusion, sample collection and preservation

The study protocols and consent forms are included in appendix 1. The local research ethics committee approved the study protocol, and all patients gave informed written consent. All diagnoses of CD and UC had been previously verified according to the British Society of Gastroenterology guidelines, using a combination of clinical, endoscopic, histological and radiological findings (Jenkins et al, 1997). Patients selected for this study were in three cohorts. The first cohort consisted of four groups: CD, UC, a non-IBD control group of patients investigated for symptoms warranting colonoscopic examination, where the final diagnosis was not IBD and histology was normal or showed only minor abnormalities, and a non-IBD inflammatory control group where the patients had microbiologically confirmed infectious colitis. The patients recruited had colonoscopic examination for clinical indications, and consented to additional biopsies being taken for research purposes. Colonoscopic biopsies were taken at six sites along the colon from each patient resulting in the collection of 122 colon biopsies from 21 patients. Additional biopsies taken adjacent to these sites were formalin-fixed and used to assess histopathological abnormality. Serial colonic biopsies were collected using standard disposable biopsy forceps. The second cohort of patients was included who underwent colectomy for CD, UC, diverticulitis or colonic carcinoma. Colonic tissue was also obtained from consenting 16 patients who had undergone colectomy for IBD or for colonic carcinoma or diverticulitis (in the case of controls). Where patients underwent colectomy, full thickness bowel tissue was obtained from 3 areas corresponding to minimal/moderate/severe inflammation where relevant and possible. Patients with colonic carcinoma served as controls, whereby normal tissue was removed from near the resection margin. The third cohort constituted 3 patients with infective diarrhoea, who underwent sigmoidoscopic examination with rectal biopsies. A rigid sigmoidoscope was inserted via the anus, with air insufflation. The extent of examination was up to 20cm, and 6 rectal biopsies were taken from the anterior rectal area at 9cm.

Colonic tissue was immediately transferred to RNA later at room temperature and stored at +4°C. Adjacent specimens were formalin-fixed for histological and immunohistochemical assessment.

Where inflammatory blood results were available, these were included and correlated with inflammatory scores and microarray results.

2.2.2 Total cellular RNA preparation, cDNA probe synthesis and microarray hybridisation, and RT-PCR

2.2.2.1 Microarray construction

Sequences corresponding to 3'UTR's sequence for all known 41 human chemokines and 21 receptors, plus related receptors, a selected collection of G protein coupled receptors (GPCR's) and their ligands, and 40 suitable housekeeping proteins (for normalisation) (see table 3.2) were amplified by PCR from IMAGE clones. Amplification oligonucleotides were designed to produce an amplicon of approximately 500bp, the 3'-UTR sequence chosen for low homology to other

genes and repetitive sequences. Alternatively, the desired fragments cloned from Universal cDNA Library Microarrays were printed using GMS 417 Microarrayer with four 50μm pins. Approximately 100pg PCR products were printed in duplicate on Hybond N+ membranes. The printed membranes were denatured, neutralised and cross-linked according to manufacturers' instructions.

2.2.2.2 Preparation of total cellular RNA from colonic biopsies and cultured cell lines

RNA was extracted from both colonic biopsies and cells lines by use of a Qiagen RNeasy total RNA extraction kit, according to manufacturer's instructions. The biopsy samples or cell line samples were disrupted and homogenised in 600μl of RLT containing 6μl of β-mercaptoethanol (β-ME). The lysates were transferred to QIAshredder spin columns, to fragment high molecular weight lysis products, and were centrifuged for 2 minutes at 21,000 g, in a micro centrifuge. Supernatants were transferred to a fresh tube, and 600μl 70% ethanol added to precipitate the RNA. The contents were gently mixed by pipetting. The resulting solution was transferred to RNeasy mini columns, and centrifuged for 15 seconds at 21,000 g. The flow-through was discarded and 700μl buffer RW1 was added to each RNeasy column, which was centrifuged for 15 seconds at 21,000 g, to wash the column. The flow-throughs were discarded and 500μl buffer RPE was pipetted onto each RNeasy column. The tubes were centrifuged for 15 seconds at 21,000 g and the flow-throughs were discarded. This was repeated and the flow-throughs were again discarded. The columns were centrifuged again for 2 minutes at 21,000 g in order to remove any remaining wash buffer. The flow-throughs were discarded, and the columns placed into new collecting tubes and 50μl RNAse-free water was pipetted directly onto the RNeasy silica-gel membrane, and left to sand for 5 minutes. Total RNA was recovered by centrifugation for 2 minutes at 21,000 g, to elute. The eluted total-cellular RNA was stored at -70°C.

2.2.2.3 RNA quantification

An RNA 1.2% agarose formaldehyde electrophoresis gel was prepared as follows: 1.8g agarose was added to 15ml 10x formaldehyde gel buffer. The 10x formaldehyde gel buffer consisted of 200mM 3-(N-morpholino)propanesulfuric acid, 50mM sodium acetate, 10mM EDTA, pH 7.0. 100ml RNase-free water was added. The mixture was heated in a microwave oven to melt the agarose, and then cooled to 65°C in a water bath. 2.7ml of 37% (12.3M) formaldehyde and 4.5μl of a 10mg/ml ethidium bromide solution were added, the gel mixed thoroughly and poured onto gel casting tray. The gel was equilibrated by electrophoresis in 1 x FA gel running buffer at 70V for 30 minutes.

The RNA/gel-loading buffer mixtures were heat-denatured for 5 minutes at 68°C, placed on ice for 1 minute, and then loaded into the gel, in addition to 18s and 28s Ribosomal standards. The gel was run at 110V for 30 minutes to 2 hours to check the yield and quantity of the RNA obtained.

A second method of RNA assay was employed, using an RNA 6000 Nano assay kit with an Agilent 2100 bioanalyser. 400μl of RNA gel matrix was centrifuged at 1500g for 10 minutes in a spin filter. 130μl of the filtered RNA gel matrix was mixed thoroughly with 2μl of the RNA dye

concentrate in an RNase free micro centrifuge tube, protected from light and stored at +4°C. 9μl of gel-dye mix and 5μl of RNA 6000 Nano Markers were loaded into an RNA chip according to manufacturer's instructions. 1μl RNA ladder was pipetted into the ladder well. 1μl of the sample was added to each of the 12 sample wells, and the chip was vortexed for 1 minute. The chip was inserted into the Agilent 2100, and an electropherogram obtained.

2.2.2.4 cDNA probe synthesis

RNA was used to synthesise cDNA probes for microarray hybridisation by reverse transcription. Oligo dT was annealed to the total RNA template as follows: The annealing mix was made from 3μl RNase-free water and 2μl Oligo dT. This was incubated at +70°C for 10 minutes and then transferred to ice for 5 minutes.

The following components were added to each annealed RNA/oligo dT mixture: 1.5μl 20mM dATP/dTTP/dGTP, 3μl 0.1M dithiothreitol (DTT) 60μl, 3μl Super RNase in 6μl Superscript II buffer, 5μl [^{33}P]-dCTP and 1.5μl of superscript II RNAse H$^-$ Reverse Transcriptase. The reaction was mixed and incubated 42°C for 1 hour. A further 1.5μl of the superscript II RNase H$^-$ Reverse Transcriptase was added, and the reaction incubated at 42°C for a further hour.

RNA was hydrolysed by addition of 1.5μl 1% SDS, 1.5μl 0.5M EDTA, 4.5μl 3M NaOH and incubated at 68°C for 30 minutes. The reactions were neutralised with 15μl 1M Tris 7.5, 4.5μl 2N HCl. 15μl 1μg/ml COT-1 DNA was added to each sample and the volume made up to 100μl with the addition of 27μl RNase-free water.

Equilibrated Bio-spin 6 chromatography columns were centrifuged for 2 minutes at 1000 g. Reverse transcribed probes were added to these columns (without disturbing the column bed) and were centrifuged for a further 4 minutes at 1000 g. The flow through containing the purified probe was denatured at 95°C for 3 minutes, and then chilled on ice for 3 minutes before hybridising to the microarray.

2.2.2.5 Microarray hybridisation and analysis

Detection and quantitation of signal hybridised to the microarray provides a measure of the relative abundance of the transcript from a target gene. The resulting expression profile were analysed by hierarchical clustering, performed blind to cohort, biopsy site and histopathology scoring, samples being grouped together solely on the similarity between gene expression profiles.

Microarrays were pre-hybridised in 8ml hybridisation solution at +55°C for 2 hours in a Techne HB1 hybridisation oven. The hybridisation solution consisted of 8ml ExpressHyb, 20μl of 10mg/ml Salmon Testes DNA, 10μl 1mg/ml Poly (dA) per hybridisation reaction. After 30 minutes, the positions of the strips were checked, and altered where appropriate, so that there were no air-bubbles, and the strips were facing inside, adherent to the glass.

The denatured purified probe was added to the hybridisation tubes containing hybridisation solution and hybridised to the microarray for 14-20 hours at 55°C.

Following hybridisation the microarrays were washed in 20ml 0.1% SDS/0.2 x SSC for 1 hour at 55°C. The solution was discarded, and a further 20ml of the same solution replaced and washed again for 1 hour at 55°C. The solution was discarded, and a further 20ml replaced, washing performed for 1 hour at 65°C. The microarrays were air dried at room temperature.

Hybridised microarrays were exposed to Low Energy PhosphorImage Screens for periods up to 1 month, and scanned by Storm860 (Molecular Dynamics). Data was extracted using IMAGENE software (BioDiscovery, Los Angeles, CA) and normalised to the average expression level of the housekeeping gene panel, with final expression levels expressed as a percentage of average of this panel. Table 1.1 lists the housekeeping genes included in the microarray. These genes code for proteins whose activities are essential for the maintenance of cell function. The 40 chosen served as reference genes against which the expression levels of chemokine genes were normalised. This method enables reliable quantitative gene expression. Data manipulations were performed with Microsoft Excel. Hierarchical clustering was performed though use of GeneSpring microarray analysis software (Silicon Genetics, Redwood City, CA).

Table 2.1: Panel of housekeeping genes included in the microarray

Human mRNA for alpha-catenin complete cds
Human mRNA for platelet-type phosphofructokinase complete cds
Human lysosomal glycosylasparaginase (AGA) gene
Human ETS2 oncogene
Human capping protein alpha mRNA partial_cds
Human mRNA for mitochon
Human cytoplasmic beta-actin gene complete cds
Unknown est hits only
Human mitochondrial ADP/ADT translocator mRNA complete cds
Human superoxide dismutase (SOD-1) mRNA complete cds
Homo sapiens protein tyrosine kinase (Syk) mRNA complete cds
Lipoamide dehydrogenase (NAD)
Unknown ~20 est only
Human mRNA for lactate dehydrogenase-A (LDH-A EC 1.1.1.27)
Human glutamate receptor 2 (HBGR2) mRNA complete cds
Human alpha-2-macroglobulin mRNA complete cds
Human glyceraldehyde 3-phosphate dehydrogenase mRNA
DAD-1 pBS AS
SLUG-1 pBS AS
Actin 5' fragment
Actin Middle fragment
Actin 3' Fragment
Deoxyhypusine synthase mRNA
Eukaryotic initiation factor 2B-epsilon
90-kDa heat-shock protein gene
HKGB06 histone H2B.1 mRNA 3' end
ADP-ribosylation factor 1 gene
Enylyl cyclase-associated protein
Cytosolic malate dehydrogenase
Haperonin protein (Tcp20)
Glutamate dehydrogenase (GDH)
DNA repair helicase (ERCC3)
Endothelin-1 (EDN1) gene
(cytosin-5)-methyltransferase
Uroporphyrinogen III synthase mRNA
Calmodulin
MRL3 = mammalian ribosome L3
ADP/ATP translocase mRNA 3' end clone
Cytochrome bc-1 complex core protein II
HnRNP C2 protein mRNA

2.2.2.6 *Real-time quantitative RT-PCR*

cDNA was synthesised from ~0.5 μg total RNA using Taqman Gold RT-PCR Kit following manufacturer's protocol. Each reaction mix included 5μl RNA, 10μl 10x RT buffer, 22μl 25mM $MgCl_3$, 20μl dNTPs, 5μl primers (random hexamers), 2μl RNase inhibitor, 29.75μl RNase free distilled water and 6.24μl Multiscribe RT. This was placed to 25°C for 10 minutes, 37°C for 60 minutes and 95°C for 5 minutes. Expression levels of CXCL's 1-3, CXCR1 and CXCR2 were measured with TaqMan primers and probes designed using Primer Express v.2, and CCR6, CCL20, CXCL8 and rRNA with TaqMan Assay Reagents. Quantitative PCRs were performed using 5μl ABI7900 with TaqMan Universal PCR Master Mix using recommended protocol. Duplicate reactions were performed with ≥ 3 dilutions of each cDNA. Expression levels in each sample were normalised by comparison to the matching rRNA level. Final data were expressed as fold-up regulation relative to an average of all uninvolved IBD samples analysed (i.e. where the biopsies were taken from a macro- and microscopically normal area, from a patient with IBD).

The relative level of up regulated expression of these chemokines in inflamed IBD colon was expressed as a percentage of the average transcript copy number detected for the non-IBD cohort normalised to 18S rRNA copy number. This serves as a good internal control in relative RT-PCR as there is little variation in expression. The normalised data was compared to the histopathological score for inflammation.

2.2.3 Histopathological assessment of colonic tissue

Haematoxylin and eosin stain (H&E) was performed on the colonic sections by laboratory technicians in the department of histopathology, Royal Free Hospital. The sections were dewaxed, rinsed in alcohol followed by water, and then stained with Harris's haematoxylin for 10 minutes. The section were washed in running tap water, followed by differentiation in acid alcohol (1% hydrochloric acid in 70% alcohol) for 10 seconds and a further wash in running tap water for 5 minutes. They were then stained with eosin for 4 minutes, and washed in tap water. Finally, the sections were dehydrated in an alcohol gradient, immersed in xylene and mounted in DPX.

Histopathological assessment was performed by Professor Dhillon (consultant histopathologist) for chronic and acute inflammation and epithelial and glandular architecture change, according to table 2.2. All scoring was undertaken in a blinded fashion.

Table 2.2: Histopathology scoring method used on colonic tissue. This scoring method was devised by the Royal Free Hospital Professor of histopathology, Professor Dhillon, as there are no accepted internationally validated alternatives.

Score A: Acute inflammation No acute inflammation Occasional lamina propria polymorphs/eosinophils Moderate numbers of lamina propria polymorphs/eosinophils, Crypt abscesses Frank pus
Score C: Chronic inflammation (lymphocytes and plasma cells) No chronic inflammation Slight increase in lamina propria mononuclear cells Moderate increase in lamina propria mononuclear cells Marked increase with > 2 lymphoid aggregates/follicles per biopsy
Score D: Destructive epithelial change None Superficial erosions Apthoid ulceration Frank ulceration
Score R: Reactive/neoplastic glandular architectural change None Occasional bifid glands Glandular disarray and/or atrophy Dysplasia

2.2.4 Immunohistochemical localisation and quantification of chemokines using immunoperoxidase technique

2.2.4.1 The technique of immunohistochemistry

This technique is used to the study epitope-localisation within tissue sections using monoclonal antibodies and an indirect amplification system. Paraffin embedded formalin-fixed sections were used. Monoclonal antibodies raised to the antigen of interest were applied to tissue sections. In order to identify the localisation of binding, and amplify the signal so that it can be detected under a microscope, a number of indirect amplification techniques were employed. This involves a colour-reaction system with biotin and horseradish peroxidase (Bancroft and Gamble, 2002).

2.2.4.2 Preparation of sections and pre-treatment methods

At room temperature, 3μm sections of tissue were de-paraffinised by immersion for 10 minutes in 200ml xylene and then brief immersion in alcohol gradient from 100% to 70% before transfer to tris buffered saline (TBS). In order to block endogenous peroxidase activity, sections were immersed in a 2% solution of hydrogen peroxide in methanol for 10 minutes. Following this, the sections were washed in running water for 10 minutes.

The following conditions were used as pre-treatment, in order to establish the optimum pre-treatment:

- No treatment
- Trypsin 10 minutes (warmed to 37°C)
- Trypsin 20 minutes (warmed to 37°C)
- High-powered microwave treatment for 20 minutes in sodium citrate buffer, then in trypsin for 15 seconds (37°C)
- High-powered microwave treatment for 25 minutes in sodium citrate buffer
- Pressure cooker treatment in sodium citrate buffer for 1 minute 30 seconds pressure cooker treatment for 1 minute 30 seconds
- Pressure cooker treatment in ethylenediaminetetraacetic acid buffer (EDTA) for 1 minute 30 seconds
- Negative control

After the pre-treatment phase, the sections were encircled on the slides using a hydrophobic pen. They were then laid out in a humidity chamber and washed in TBS.

Following the blockade of endogenous peroxide activity, non-specific background immunoreactivity was blocked by incubation in 200μl/slide in either a 1% solution of normal horse serum (NHS), a 5% solution of foetal calf serum (FCS), or a 3% / 5% solution of milk powder, in TBS buffer. This solution was shaken off the slides after 20 minutes. Following incubation period, sections that were to be used as negative controls (i.e. with no primary antibody applied) did not have the NHS removed.

2.2.4.3 Primary antibody application

For each slide, 200µl of antibody was applied at a set dilution, in TBS buffer, containing 5% foetal calf serum where indicated in the text. The sections were incubated either for 1 hour at room temperature in a humidity chamber at room temperature, or overnight (approximately 18 hours) at +4°C in a humidity chamber.

After the primary antibody incubation, sections were washed in several changes TBS for 10 minutes.

2.2.4.4 Secondary antibody incubation

Link antibody incubation was then performed, using biotinylated rabbit-anti-mouse at a 2% dilution in TBS buffer containing 2% normal horse serum, or 5% foetal calf serum, for 40 minutes The sections were washed in TBS buffer for 10 minutes.

Following this, the next stage of the amplification signal was achieved using peroxidase conjugate complex (ABC). This was used at a dilution of 2% avidin biotin + 2% normal horse serum or 5% foetal calf serum in TBS buffer for 30 or 40 minutes, prepared 30 minutes in advance. The sections were again washed in TBS for 10 minutes.

2.2.4.5 Application of DAB

Bound peroxidase was visualised with di-amino-benzidine (DAB) solution, applied to each slide and washed off with TBS when staining was seen to be optimised using a light microscope. The slides were placed in a staining rack, in running tap water. This was immersed in haematoxylin for 4 minutes to counterstain the sections, then in running tap water. The sections were then dipped twice in acid alcohol, washed again in running tap water, then immersed in sodium tetraborax for 2 minutes to stain the haematoxylin nuclei blue. Following this, the sections were washed again in running tap water, then dehydrated by brief dips in 3 troughs containing absolute alcohol at increasing concentrations, finishing with immersion for a few seconds in 2 troughs containing xylene. The sections were mounted in DPX and viewed by light microscopy.

2.2.5 Analysis of Cell lines

2.2.5.1 Cell propagation

3 sets of different passage-number Caco-2 and HT29 cells were incubated at 37°C, in 2 x 75cm cell-culture flasks, containing 10ml of DME medium, supplemented with 10% FCS, 2mmol/l glutamine, 1% non-essential-amino-acids and 5ml antibiotics, or 10ml McCoy's 5A medium supplemented with 10% FCS, 2mmol/l glutamine and 1% non-essential amino acids, respectively. Growth and possible infection were monitored. When the cells had formed a confluent monolayer, with dome formation, the medium was aspirated, and the cells were washed with approximately 10ml room temperature-phosphate buffer solution (PBS) to remove the adherent medium. 3ml of trypsin were added to each flask, and incubated for 8 minutes, until the most of the cells were seen to be detached when viewed by light microscopy. The flasks were tapped firmly to detach remaining cells.

The trypsin/cell mixtures were centrifuged at 10,000g at room temperature 5 minutes. The supernatant was discarded and the cell pellet re-suspended gradually in 4ml medium, made up to a final volume of 20ml.

2.2.5.2 Cell Count and viability assessment

15µl of the cell suspension were added to 15µl of trypan blue 0.4%. This was mixed gently, added to a cytometer with a cover slip, and viewed under a light microscope. The viable cells were counted within 6 grids, and an average calculated. The dead cells were also counted within the same grids and the cell viability calculated by the standard grid equation total number of live cells x 10^4 x 2 /ml (dilution factor of 2).

2.2.5.3 Cell stimulation

20 x 10cm well plates were used. 1.5 x 10^6 cells were added to 10ml medium. The plates were incubated and medium changed every 3 days. At 3-days post confluence, combinations of 1µM benzamide, 10µM trichostatin, 10ng/ml TNF-α, 10ng/ml IL-1β and 10µg/ml *E.coli* lipopolysaccharide were applied to the Caco-2 cells, as detailed in table 2.3. At 3 days post confluence, the HT29 cells, combinations of 10ng/ml TNF-α, 10ng/ml IL-1β and 10µg/ml *E.coli* lipopolysaccharide were applied as detailed in table 2.3.

Table 2.3: Stimulation solutions applied to Caco-2 cells. The table details quantification of the additives.

Stimulation	**Solution added**
Nil	10ml medium
IL-1β	10µl of 10µg/ml Il-1β in 10ml medium (10ng/ml)
TNF-α	1µl of 0.1mg/ml TNF-α in 10ml medium (10ng/ml)
Benzamide (1µM)	100µl of 100mM benzamide in 10ml medium
Trichostatin A 10µM	100µl of 1mMol Trichostatin A in 10ml medium
E.coli LPS 10µg/ml	100µl of 1mg/ml of LPS in 10ml medium

At 2-, 4- and 18-hour time points, the supernatants were removed from the relevant plates and stored at -70°C.

5ml sterile phosphate buffered saline (PBS) was added to each of these plates, and rocked gently, to wash remaining FCS from the cells. The PBS was then aspirated and discarded. 3ml trypsin were added to each plate, and incubated at 37°C for approximately 8 minutes, to detach the cells. The trypsin/cultured cell mixes were centrifuged for 5 minutes at 10,000g. The supernatants were discarded, and the cell pellets re-suspended in 5 ml sterile PBS. The suspensions were again centrifuged for 5 minutes at 10,000 g. The supernatants were discarded, and the remaining pellets re-suspended in 1ml sterile PBS, and transferred to sterile eppendorfs. These were centrifuged at 10,000 g for 5 minutes, and the supernatants discarded. The resulting dry cell-pellets were frozen at -70°C.

2.2.6 Quantitative determination of chemokine protein concentrations in cell culture supernatants

2.2.6.1 The technique of ELISA

This assay incorporated the quantitative sandwich enzyme immunoassay technique. A monoclonal antibody specific for one of CCL20, CXCL8, CXCL1 or CCL5 had been pre-coated onto 4 microplates. When standards and samples were pipetted into the well, any antibody-specific chemokine present was bound by the immobilised antibody. After washing away any unbound substances, an enzyme-linked polyclonal antibody specific for the appropriate chemokine was added to the wells. Following a wash to remove any unbound antibody-enzyme reagent, a substrate solution was added to the wells and colour developed in proportion to the amount of chemokine bound in the initial step. The colour development was stopped and the optical densities determined.

The chemokine standards were reconstituted with distilled water according to the manufacturer's guidelines, to produce a stock which was diluted to form the recommended standards.

2.2.6.2 ELISA procedure

The sample or standards were added to the appropriate wells, diluted according to specific manufacturer's guidelines. The ELISA plate was covered, and incubated for the recommended length of time at room temperature.

Using an auto washer, each well was aspirated and washed the recommended number of times. This was programmed to deliver 400µl of wash buffer to each well during each cycle. All liquid was removed at each step, and after the last wash, the plate was inverted and blotted.

Chemokine conjugate was added to each well and incubated at room temperature for the recommended time (1-2.5 hours, depending on the antibody). The washing step was repeated, for recommended number of cycles (3-6). During the washing process, the substrate solution was prepared. Colour reagents A and B were mixed together in equal volumes, within 15 minutes of use. This was placed in darkness until the ELISA plate was ready. When the washing process was complete, 200µl of substrate solution were added to each well using an ELISA multi-pipette. This was incubated for 30 minutes at room temperature in the dark.

Details for CCL20 ELISA

The CCL20 standard was reconstituted with distilled water to produce a stock of 5000pg/ml. After 20 minutes of gentle agitation, this was diluted with the R and D standard calibrator dilutent RD6-21 to make 7 x 50% serial dilutions, of 500pg/ml, 250pg/ml, 125pg/ml, 62.5pg/ml, 31.2pg/ml, 15.6pg/ml, 7.8pg/ml. The calibrator diluent served as the zero standard (0pg/ml). 100µl of assay diluent RD1-57 was added to each well, followed by 100µl of standard or sample. The ELISA plate was covered, and incubated for 2 hours at room temperature. Each well was then aspirated and washed three times with the Quantikine ELISA wash buffer. 200µl of CCL20 conjugate was added to each well. The plate was covered, and incubated for 2 hours at room temperature. Following this, the washing step was repeated, for 3 cycles. 200µl of substrate solution were added to each well, and the procedure completed as described above.

Details for CXCL8 ELISA

The CXCL8 standard was reconstituted with 5ml calibrator standard Quantikine diluent RD5P to produce a stock of 2000pg/ml. After 20 minutes of gentle agitation, this was diluted with calibrator diluent RD5P (1X) to make 7 x 50% serial dilutions of 2000pg/ml (stock), 1000 pg/ml, 500pg/ml, 250pg/ml, 125pg/ml, 62.5pg/ml, and 31.2pg/ml. The calibrator diluent served as the zero standard (0mg/ml). 100µl of assay diluent RD1-8 was added to each well, followed by 50µl of standard or sample. 100µl of conjugate was added to each well, and the plate was agitated gently. The plate was covered and incubated for 2 hours at room temperature, and then washed in Quantikine wash buffer 6 times using the automated washer. 200µl of substrate solution was added to each well, and the ELISA was completed as described above.

Details for CXCL1 ELISA

The CXCL1 standard was reconstituted with 5ml Quantikine calibrator diluent RD5B produce a stock of 1000pg/ml. After 20 minutes of gentle agitation, this was diluted with calibrator diluent RD6-21 to make 6 x 50% standard concentrations of 1000pg/ml, 500pg/ml, 250pg/ml, 125pg/ml, 62.5pg/ml, 31.2pg/ml. The calibrator diluent alone served as the zero standard (0pg/ml). 200µl of the standard or sample were added to each well. The plate was covered and incubated for 1.5 hours at room temperature. Each well was aspirated and washed three times in Quantikine wash buffer. 200µl of CXCL1 conjugate was added to each well. The plate was covered and incubated for 1 hour. The washing step was repeated, again for 3 times. 200µl of substrate solution (prepared as described in section 2.2.4.2) were added to each well. This was incubated for 15 minutes at room temperature in the dark.

Details for CCL5 ELISA

The CCL5 standard was reconstituted with distilled water to produce a stock of 2000pg/ml. After 20 minutes of gentle agitation this was diluted to make 7 x 50% serial dilutions, of 2000pg/ml, 1000 pg/ml, 500pg/ml, 250pg/ml, 125pg/ml, 62.5pg/ml, 31.2pg/ml. The calibrator diluent served as the zero standard (0pg/ml). 100µl of assay diluent RD5H was added to each well, followed by 100µl of standard or sample. The ELISA plate was covered and incubated for 2 hours at room temperature. Each well was aspirated and washed three times in Quantikine wash buffer. 200µl of RANTES conjugate was added to each well. The plate was covered and incubated for 1 hour at room temperature. The washing step was repeated for 3 times. 200µl of substrate solution was added to each and incubated for 30 minutes at room temperature in the dark.

2.2.6.3 Optical densometry

50µl of the stop solution was then added to each well, and the optical density of each well was obtained using a microplate reader set to 450nm. The wavelength correction was set to 540nm. The duplicate readings for each standard and sample were averaged and subtracted from the average zero standard optical density.

2.2.7 Flow cytometric analysis of colonic biopsies

Colonic biopsies were obtained as described in section 2.2.1.1. They were placed directly into calcium and magnesium-free Hanks Balanced Salt Solution for 10-20 minutes at +37°C on a rocker, to strip the epithelial layer from the lamina propria. Mechanical disruption was then performed using a vortex. The fluid was retrieved. 2ml of the cell dissolution solution was added to the biopsy, and again rocked for 10-20 minutes 37°C. This was mechanically disrupted, and the process repeated a further 2 times. The remaining tissue was digested with collagenase 4 mg/ml for 2-3 hours. 1ml of 2μg/ml collagenase in RPMI medium with 10% FCS was added to the lamina propria. This was vortexed. Saline was added to both tubes to make up to 10ml. These were then centrifuged 15000g for 10 minutes. The supernatants were discarded, pellets re-suspended in 10ml saline, and re-spun at 15000rpm for a further 10 minutes. The tissue was washed twice with PBS 2ml/sample. The supernatants were discarded and the pellets resuspended in the drops of PBS remaining. 2ml PBS/albumin/paraformaldehyde per tube was added, and stored at +4°C.

A single-cell suspension was prepared from each compartment and stained with conjugated antibodies to CXCR1, CXCR2, CCR6 and CCL20 (R&D). Analysis was performed by 4-colour flow cytometry (Dako, UK) with lineage markers for T and B cells, monocytes, neutrophils, colonocytes and APC's (Coulter-Immunotech and Serotec UK). Isotype control reagents were used throughout.

2.2.8 Stimulation of colonic epithelium in colonic biopsies

9 biopsies were taken from each of 6 patients, from the rectosigmoid area using standard disposable biopsy forceps. The 1st was placed directly into RNA later, and the remaining 8 were placed into 4ml enriched diluted RPMI colonic epithelial cell culture medium (100ml RPMI, 100ml distilled water, 0.94g NCTC, 0.22g sodium bicarbonate, 10% foetal calf serum). These were then orientated on 5mm^2 sterile sponge squares with the help of a light microscope, with epithelium facing upwards. They were immersed in 4ml RPMI medium with the following additions, in 5cm petri dishes, and placed in an enclosed plastic container filled with 95% oxygen, and incubated at 37°C on a rocker, for 2 or 4 hours:

- Nil added
- 10ng/ml TNF-α
- 10ng/ml IL-1β
- 10ng/ml TNF-α + 10ng/ml IL-1β

At 2 and 4 hours the appropriate biopsies were retrieved and placed into RNA later at room temperature and stored at +4°C.

2.2.9 Primary colonic epithelial culture and stimulation

2.2.9.1 Epithelial cell separation

3 sets of 2cm^2 sections of normal colonic epithelium were placed directly into Cell Dissociation Solution. The tissue sections were obtained from 3 patients who underwent colectomy for colonic carcinoma, with consent and ethical approval. These were incubated at 37°C for 45 minutes, with mechanical agitation at 5-minute-intervals. The Cell Dissolution Solutions were

replaced twice. The lamina propria was placed in RNA later and stored and room temperature. The solutions containing the epithelium were centrifuged at 10, 000g at room temperature for 10 minutes, and the pellets were re-suspended in PBS twice to wash the cells.

2.2.9.2 Epithelial cell propagation

50μl of the cell pellets were re-suspended in 4ml of 50% RPMI medium containing 50% distilled water, 9.4g/litre NCTC, 13.1mmol sodium bicarbonate, 10%FCS and 2% antibiotics, with the addition of the following pro-inflammatory cytokines: nil, 10ng/ml TNF-α, 10ng/ml IL-1β or 10ng/ml TNF-α and 10ng ml IL-1β. These were incubated at 37°C for 2 hours.

2.2.9.3 Cell count and viability assessment

An assessment of the cell count and viability was performed as described in section 2.2.3.2.

2.2.9.4 Cell pellet formation

The enriched medium/cell mixes were centrifuged at 10 000g for 10 minutes, and the supernatant discarded. The pellets were washed twice in PBS and stored in RNA later.

2.2.9.5 RNA extraction

RNA was isolated as described in section 2.2.1.2.

2.2.9.6 Microarray hybridisation and analysis

Hybridisation and microarray analysis was performed as described in section 2.2.1.5

Chapter 3

Quantification of chemokine RNA in colonic tissue

3.1 Introduction

3.2 Microarray hybridisation analysis of total cellular RNA obtained from colonic tissue

- 3.2.1 Sample preparation
- 3.2.2 Array results
- 3.2.3 Discussion

3.3 Real time quantitative PCR (RT-PCR) on colonic tissue

- 3.3.1 Background
- 3.3.2 RT-PCR technique
- 3.3.3 Results
- 3.3.4 Conclusion

3.4 Discussion

3.1 Introduction

Recent advances in gene expression profiling technology have enabled construction of a custom cDNA microarray incorporating the entire chemokine superfamily and their receptors. Detection and quantisation of signal hybridised to the microarray provides a measurement of the relative abundance of target genes and included every known chemokine recognised in 2001 (Skelton et al, 2003). As chemokines determine the extent, type and duration of leukocyte infiltration, characterisation of the pattern of expression within normal, non-inflamed and inflamed IBD, and infectious colitis is likely to further understanding of disease process in IBD.

3.2 Microarray hybridisation analysis of total cellular RNA obtained from colonic tissue

3.2.1 Sample preparation

Patient and sample inclusion, methods for inflammatory scoring, RNA preparation, cDNA probe synthesis, microarray hybridisation and quantisation are detailed in section 2.2. Disease activity in patients with IBD ranged from focally normal to moderate/severe. An RNA assay was performed on each sample, as described in 2.2.3, using the Agilent bioanalyser. Graph 3.1 represents a sample electropherogram obtained. Figure 3.1 represents the pseudo-gel appearance with each lane corresponding to a different sample. The patient details for each lane represented are outlined in table 3.1. A conventional gel is picture in figure 5.1.

3.2.2 Array results

The expression profiles analysed by hierarchical clustering are illustrated in figure 3.2.
Table 3.2 indicates which genes were strongly, weakly expressed or not expressed at all. The array values for these chemokines are listed in table 3.3.

Graph 3.1: Electropherogram to illustrate the RNA assay from minimally diseased UC lamina propria (sample 139) and mildly diseased whole UC tissue (sample 141), including fluorescence (y-axis) and time in seconds (x-axis). 2 ribosomal peaks are visible, and 1 marker peak, demonstrating good RNA preparation.

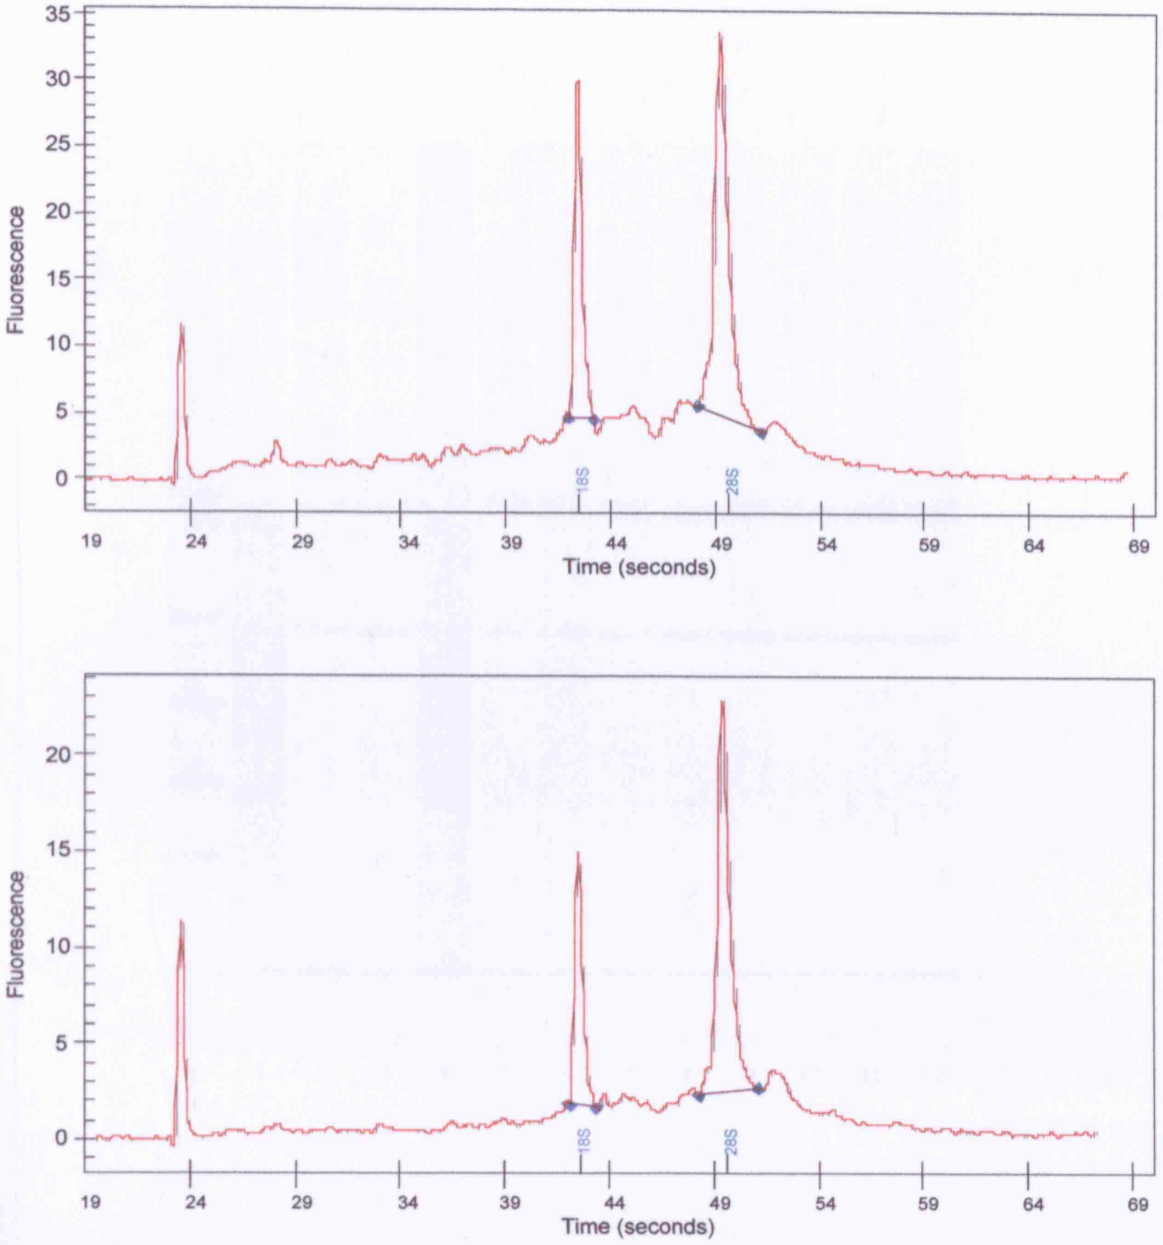

Figure 3.1: Pseudo-gel lanes to illustrate the RNA assay from samples listed in table 3.1. Two ribosomal peaks are visible, and one marker peak, demonstrating good RNA preparation. L=ladder.

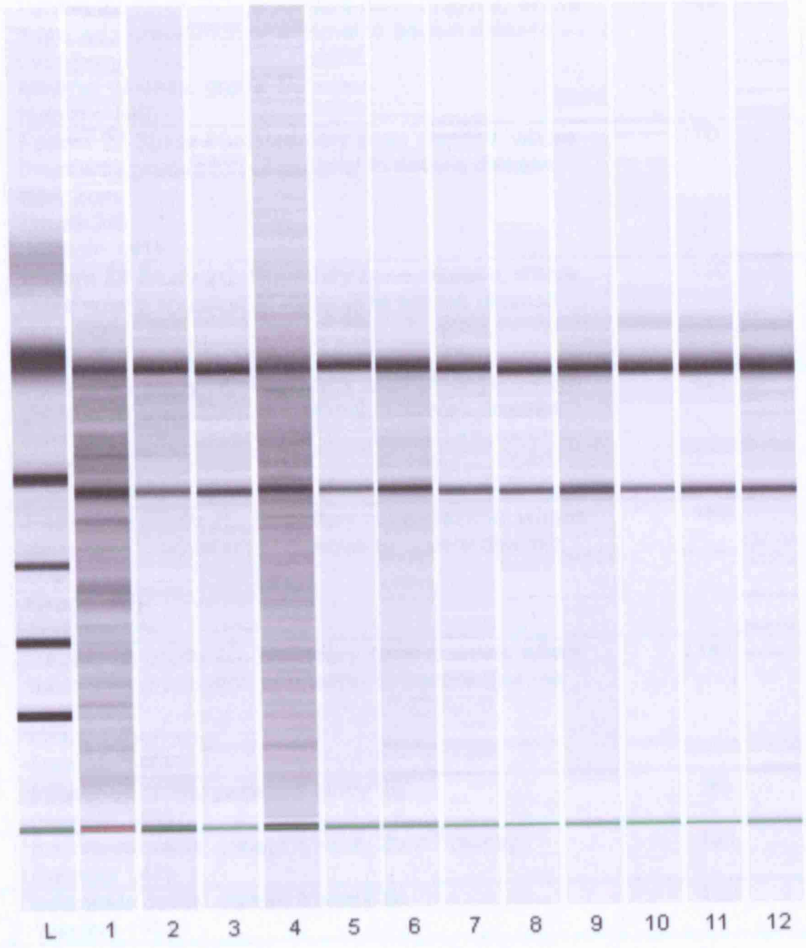

Table 3.1: Clinical details and corresponding semi-quantified RNA concentration (ng/μl) from samples included in graph and figure 3.1, assessed using the Agilent system.

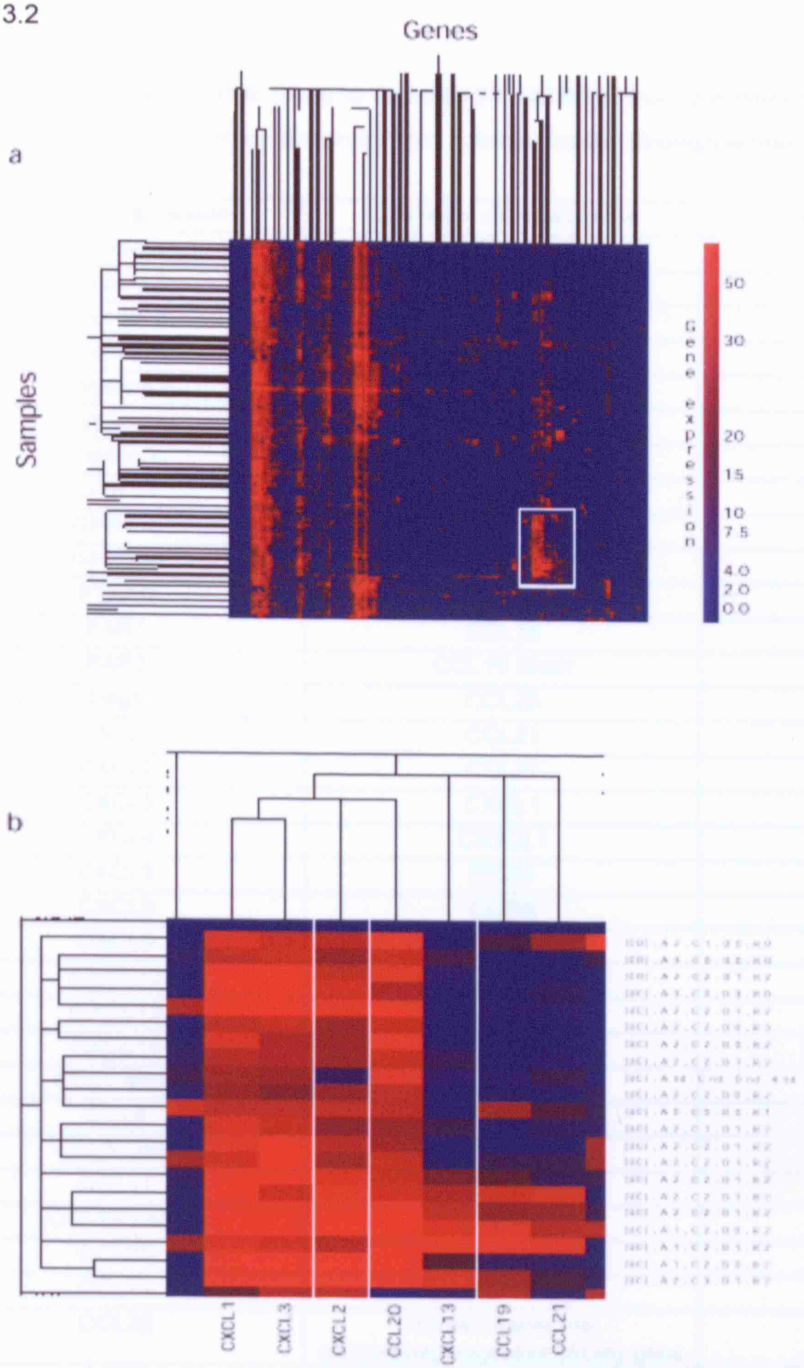
Sample Peak	Sample description	RNA Concentration (ng/μl)	rRNA ratio 28S/18S
1	Patient 22 Study 2C Severe UC, stripped lamina propria (sample 137)	192	1.15
2	Patient 22 Study 2C Severe UC, stripped lamina propria (sample 138)	45	1.76
3	Patient 22 Study 2C Minimal diseased area in UC, stripped lamina propria (sample 139)	146	1.79
4	Patient 22 Study 2C. Boundary zone disease, where there was graduation of minimal to severe disease over 2cm. Minimal disease: grade 1/6 (sample 140)	43	1.22
5	Patient 22 Study 2C. Boundary zone disease, where there was graduation of minimal to severe disease over 2cm. Grade 2/6 (sample 141)	70	2.08
6	Patient 22 Study 2C. Boundary zone disease, where there was graduation of minimal to severe disease over 2cm. Grade 3/6 (sample 142)	150	1.59
7	Patient 22 Study 2C. Boundary zone disease, where there was graduation of minimal to severe disease over 2cm. Grade 4/6 (sample 143)	127	1.95
8	Patient 22 Study 2C. Boundary zone disease, where there was graduation of minimal to severe disease over 2cm. Grade 5/6 (sample 144)	192	1.85
9	Patient 22 Study 2C. Boundary zone disease, where there was graduation of minimal to severe disease over 2cm. Grade 6/6 (sample 145)	141	1.48
10	Infectious colitis: patient 4 study 2b (sample 146)	96	2.33
11	Infectious colitis: patient 4 study 2b 2nd biopsy (sample 147)	191	2.29
12	Infectious colitis: patient 5 study 2b (sample 148)	122	2.27

Figure 3.2



Hierarchical clustering of gene expression data from colonic biopsy tissue. Genes represented on the microarray are clustered along the horizontal axis, while colon biopsy samples (including from 13 IBD patients and 9 normal controls) are clustered along the vertical axis (a). The bar on the right hand side gives an indication of the level of gene expression: blue=low, red=high. Data are the relative amount of gene expression given as a percentage of the mean of the expression levels of a group of 40 housekeeping genes present on the array. Dendograms reveal up regulation of expression of a distinct subset of chemokines within a group of inflamed colon samples (white box). A cluster of 21 biopsies, taken from 5 UC and 1 CD patients, exhibited an expression profile clearly distinct from the other 101 profiles analysed. Within this exceptional cluster, much higher levels of gene expression were observed for a group of four chemokines: CXCL1, CXCL2, CXCL3, and CCL20, in comparison to other samples. An expanded view of this exceptional cluster of samples is shown in (b), which also shows histopathological scores on the right.

Table 3.2: Categories of level of gene expression, obtained from the semi-quantitative assessment of the microarray obtained from colonic tissue (strong/low/nil).

Strongly expression	Low level of expression	No expression
Trypsin 1	CCL1 long	Thrombin
Trypsin 2	CCL2	Elast 2B Short
Trypsin 3	CCL3	FPRL1
Trypsin 4	CCL5 Short	P2Y5
Tryptase a	SCYA3L	H963 short
Tryptase b	CCL8	P2Y9
Caldecrin	CCL13	EBI2
GPR16	CCL14	GPR34 short
GPR115	CCL15	GPR34 long
GPR128	CCL16	GPR38
PTAFR	CCL17 Long	GPR15
PAR1	CCL18	GPR31
PAR3	CCL19 Short	GPR32 long
Edg5	CCL25	CRTH2
CXCL1	CCL21	GPR44
CXCL2	CCL27	CNR2
CXCL3	CXCL1	P2Y2
CXCL4	CX3CL1	Edg2
CXCL5	CCR4	Edg3
CXCL8	CCR5	Edg8
CXCL9	CCR6	CB2
CXCL10	CCR7	EMR1
CXCL13	CCR11	CCL7 Short
CXCL14	CXCR3	CCL17 Short
CCL1 short	CXCR5	CCL22
CCL4	CCXCR1	CCL23
CCL5 Long	D6	CCR1
CCL11	DARC	CCR2
CCL19 Long	CCRL2	CCR3 Short
CCL20	hm74	CCR3 Long
CCL24	RDC1	CCR8 short
CCL26	Human lysosomal glycosylasparaginase (AGA) gene	CCR8 long
CCL28	Unknown ~20 est only	CCR9
CCR10	Eukaryotic initiation factor 2B-epsilon	CXCR1
CXCR4	Endothelin-1 (EDN1) gene	CXCR2
		CX3CR1
		TYMSTR
		Human glutamate receptor 2 (HBGR2) mRNA complete cds
		SLUG-1 pBS AS

Table 3.3: Relative expression levels of CCR6, CXCL1, CXCL2, CXCL3, CCL20 and actin, obtained by semi-quantitative assessment of the microarray result from colonic biopsy tissue, with inflammatory quotients. Where the level is less than 10-15, it is not significantly detected.

Disease	Patient number	Biopsy number	A+C	ESR	CRP	CXCL1	CXCL2	CXCL3	CCL20	CCR6	Actin

Table 3.4: Relative expression levels of CCR7, CCL19, CCL21, CXCL13 and CXCR5, obtained by semi-quantitative assessment of the microarray result from colonic biopsy tissue, with inflammatory quotients. Where the level is less than 10-15, it is not significantly detected.

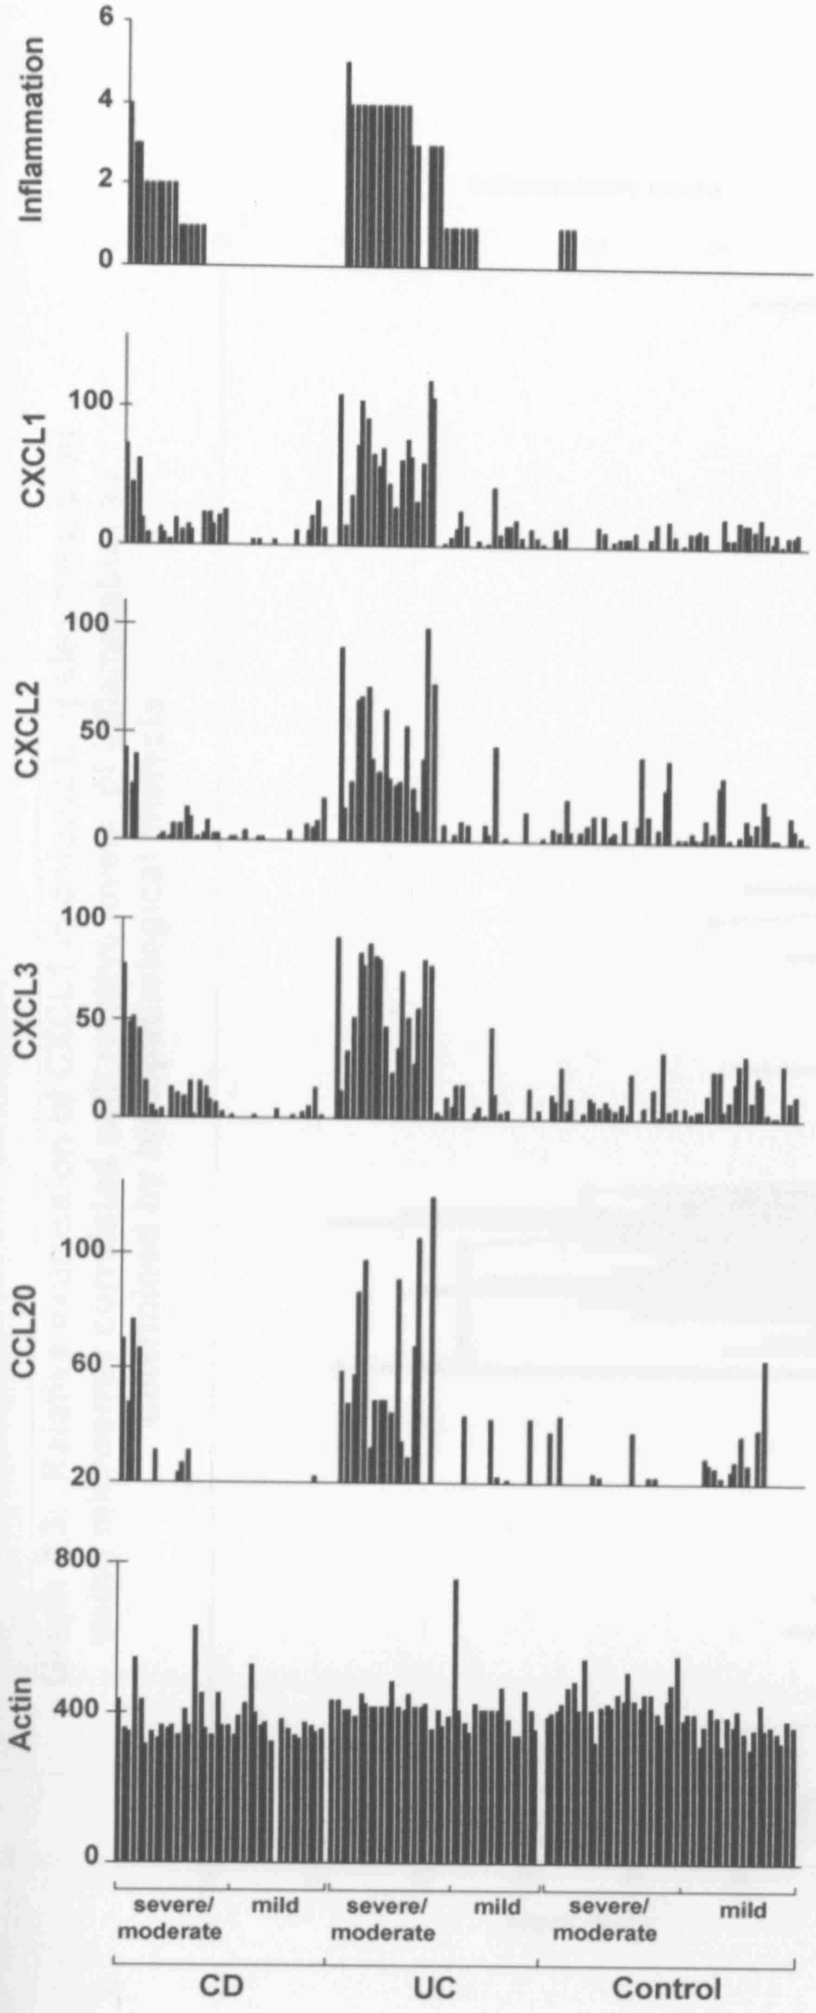
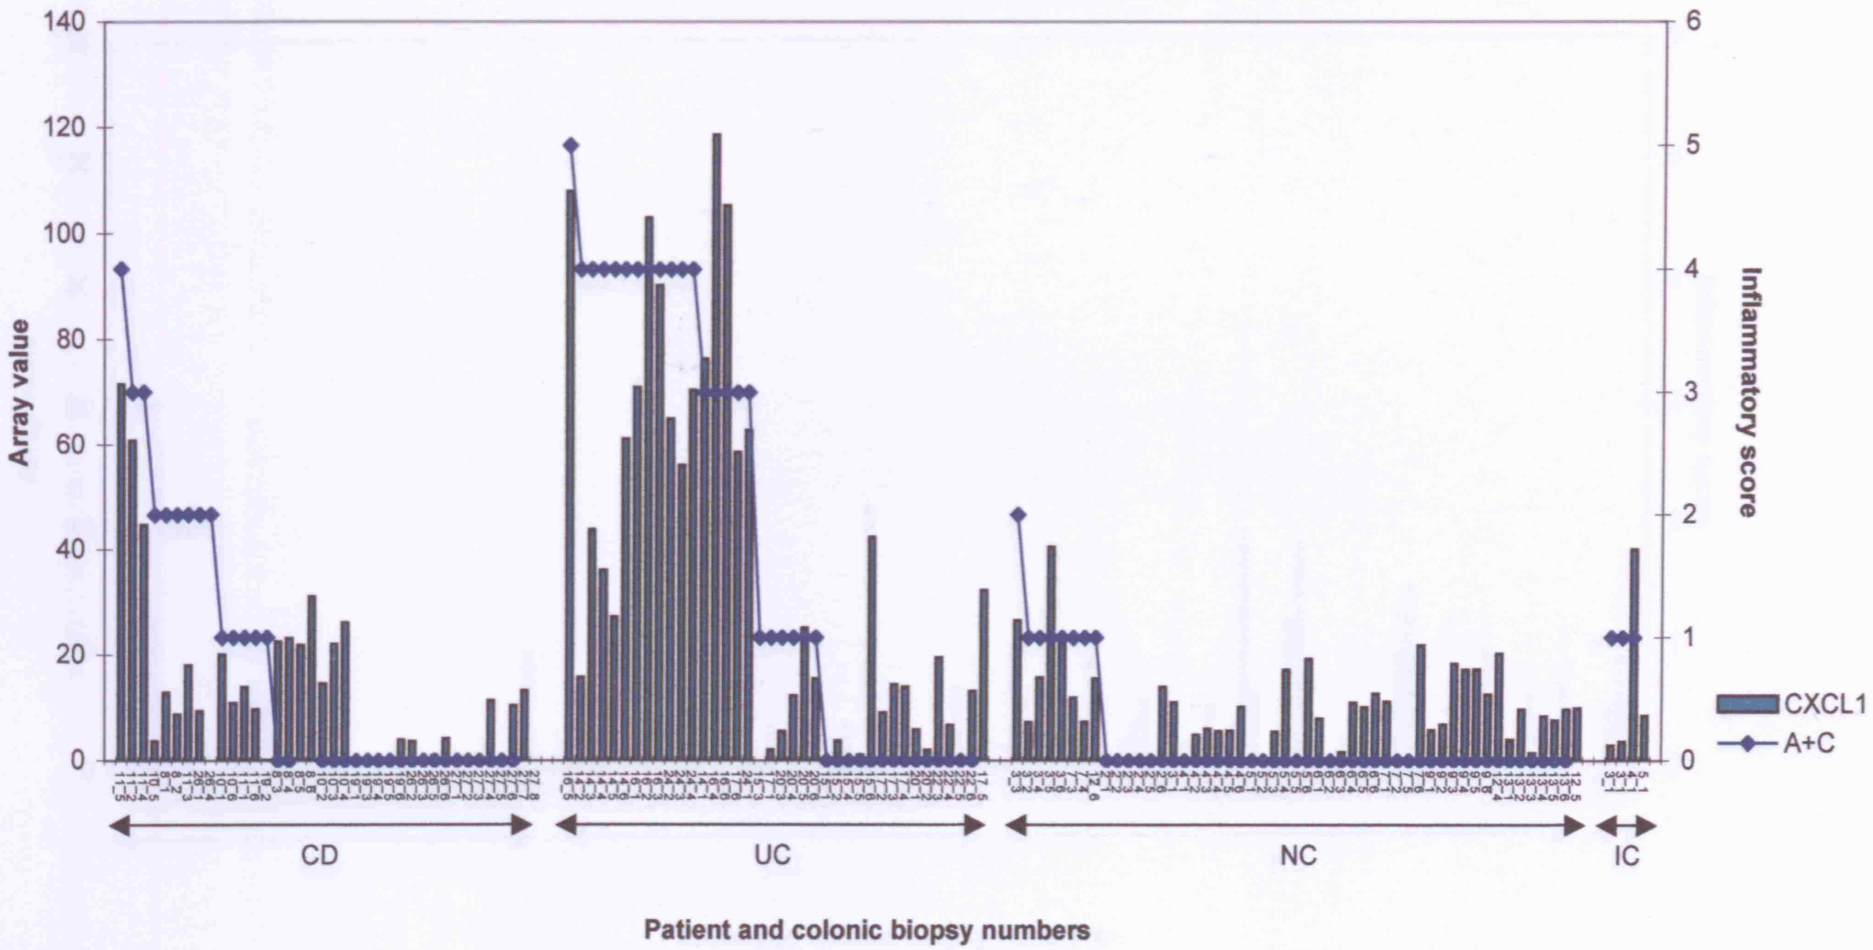


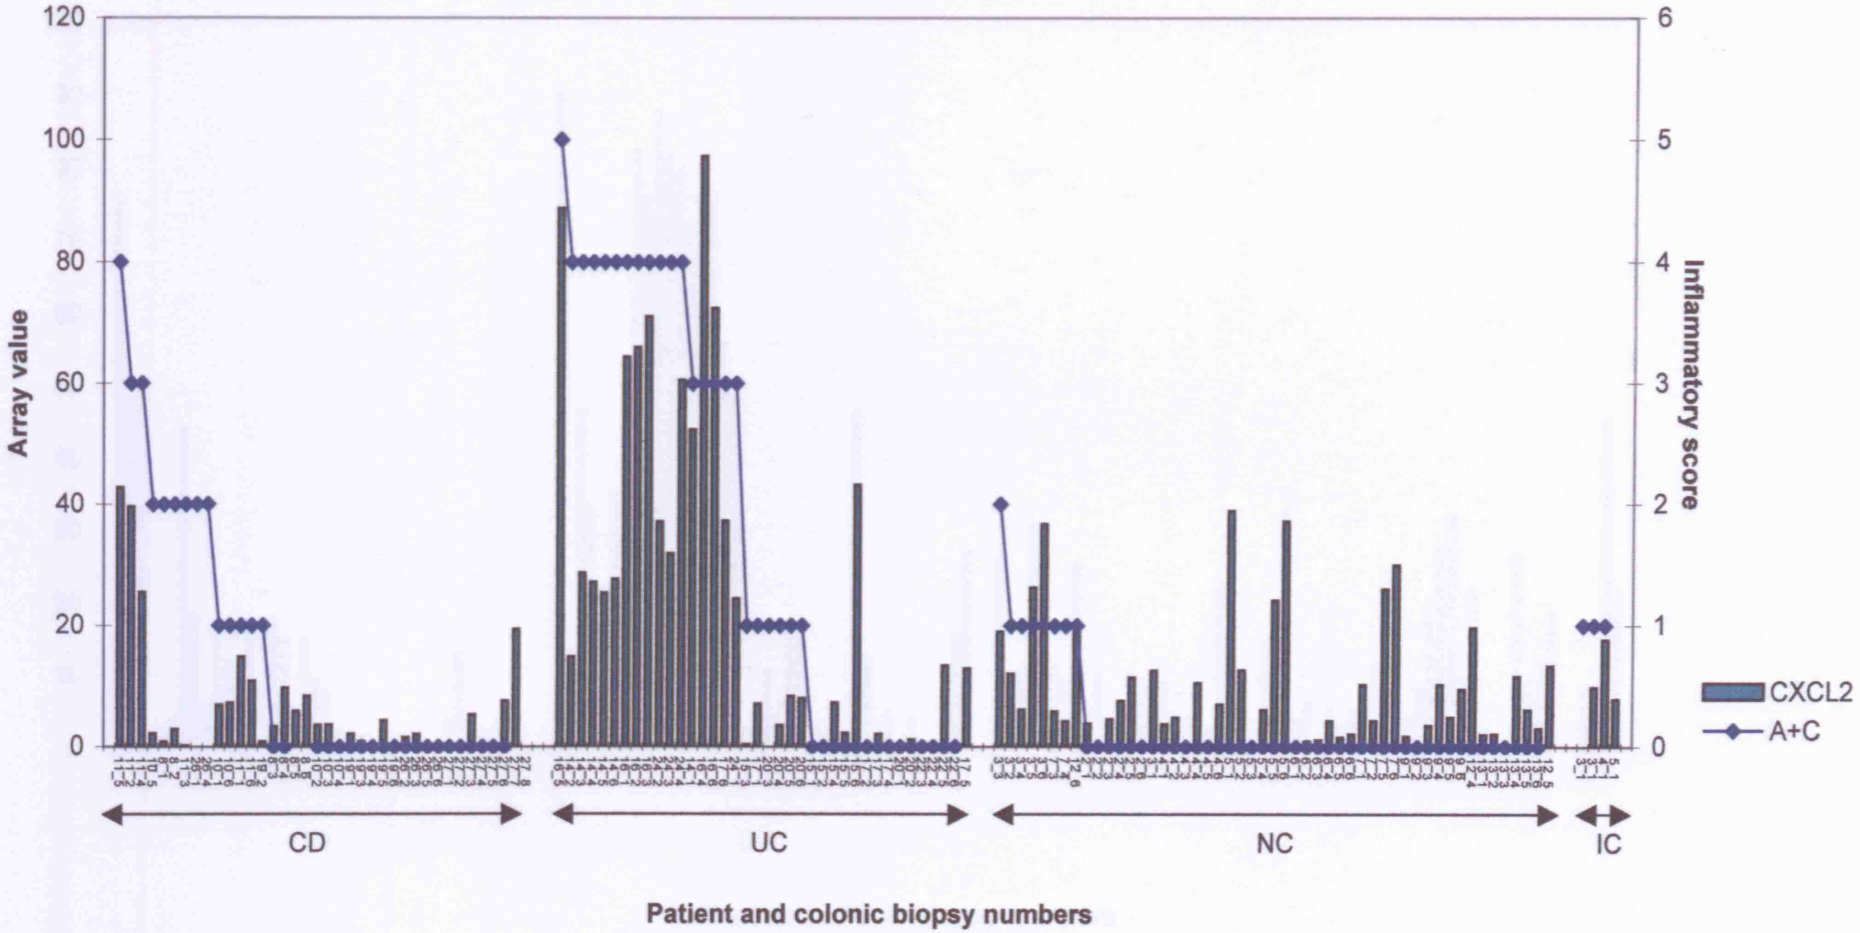
Graph 3.2: Data from colonic biopsy tissue. Relative expression levels of selected chemokines and actin measured by microarray analysis, in comparison to relative levels of inflammation as determined by histopathological analysis. Inflammation is given as a cumulative score for acute and chronic inflammation. Samples are grouped according to CD, UC or control cohort.

Graph 3.3: Relative expression of CXCL1 in colonic biopsies measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



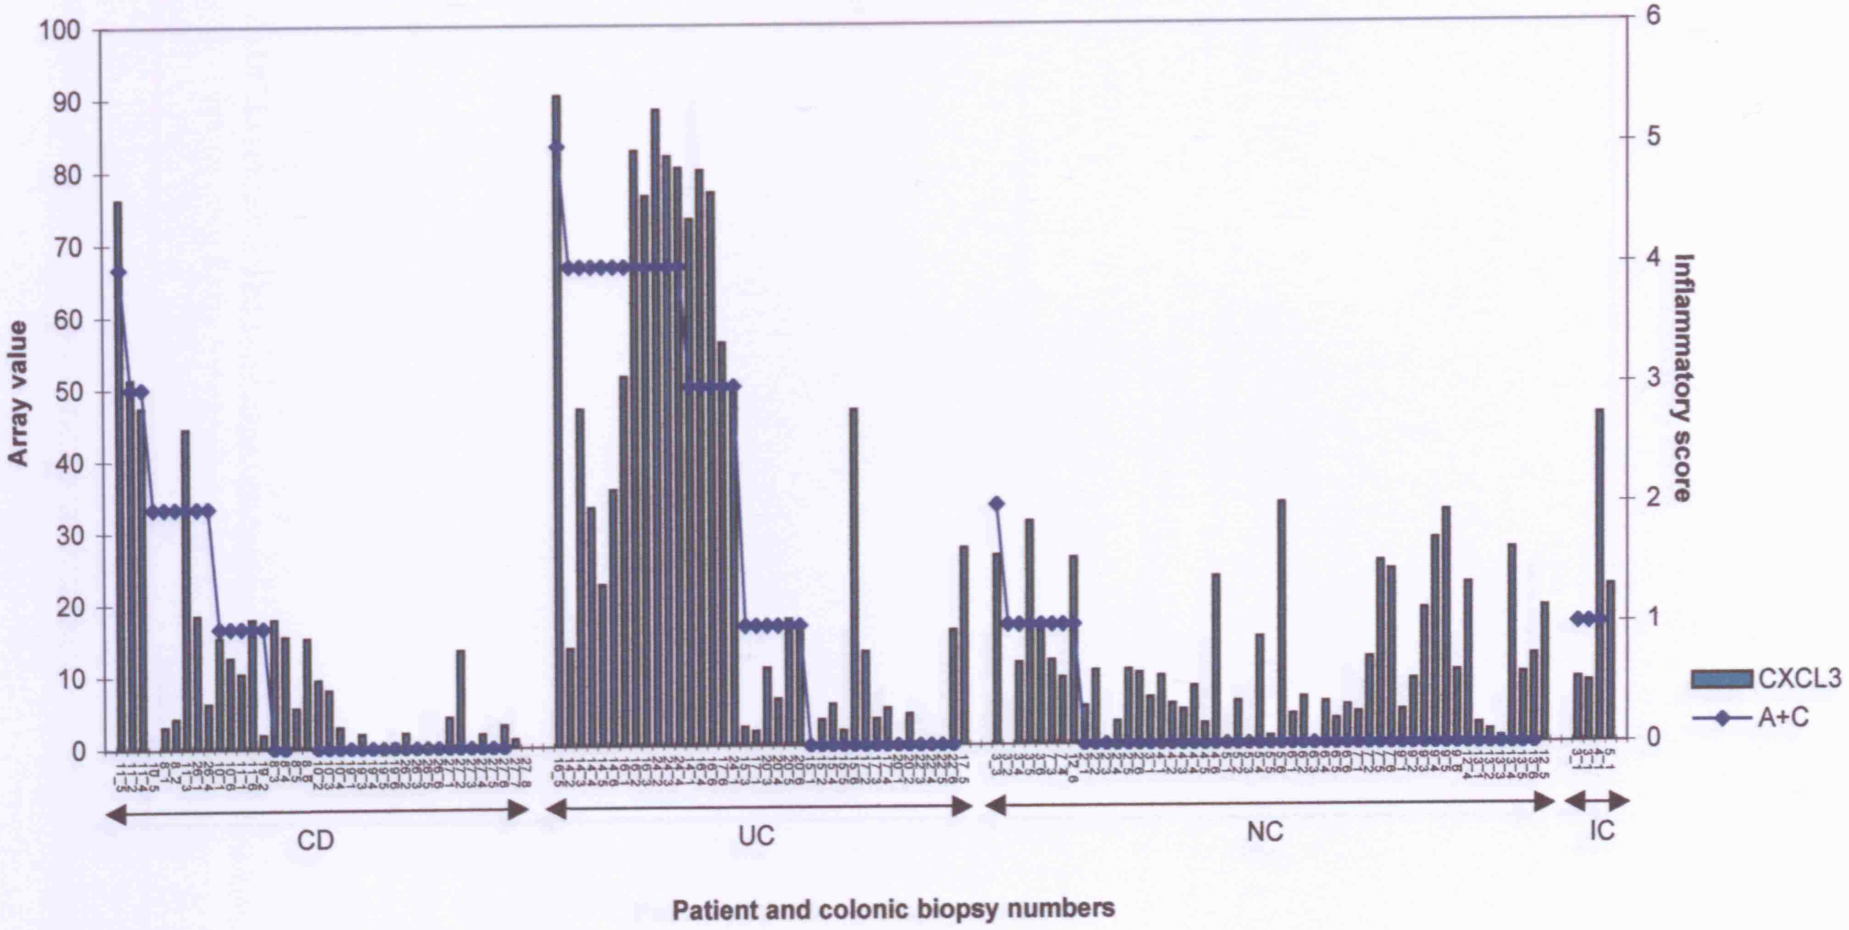
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and colonic biopsy details are outlined in appendix table 1. NC=normal control, IC=inflammatory control.

Graph 3.4: Relative expression of CXCL2 in colonic biopsies measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



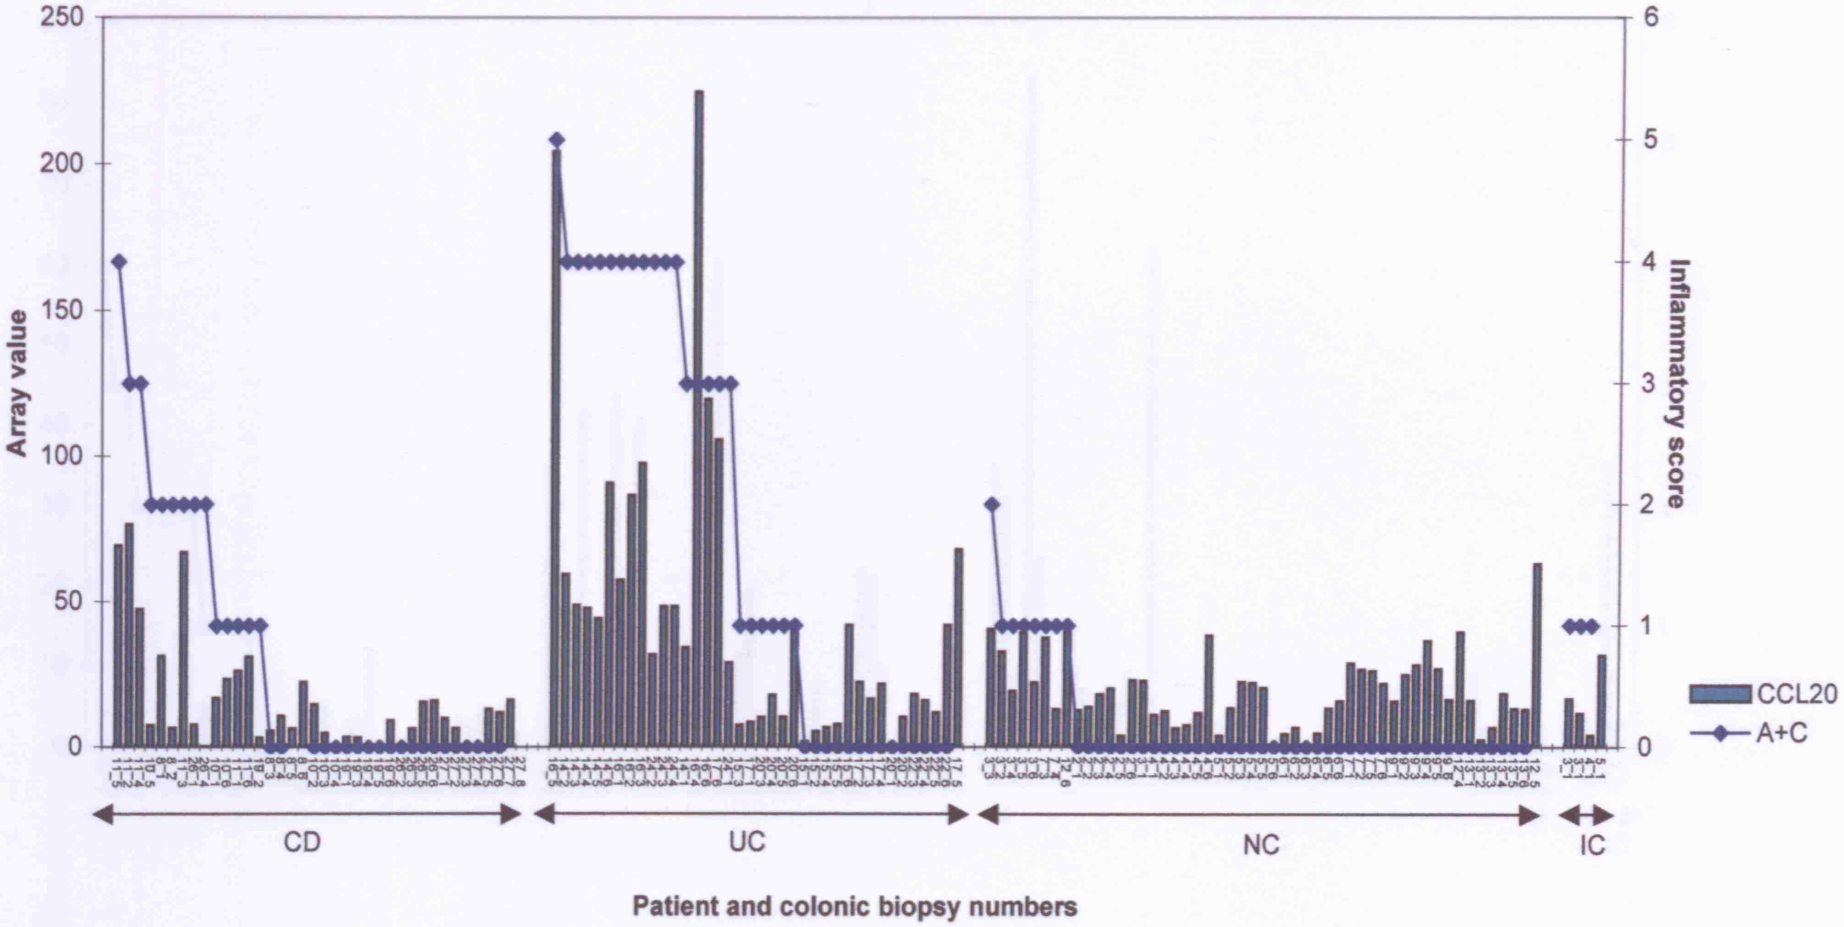
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.1). Patient and colonic biopsy details are outlined in appendix table 1. NC=normal control, IC=inflammatory control.

Graph 3.5: Relative expression of CXCL3 in colonic biopsies measured using microarray analysis correlated with relative levels of inflammation as determined by histopathological analysis



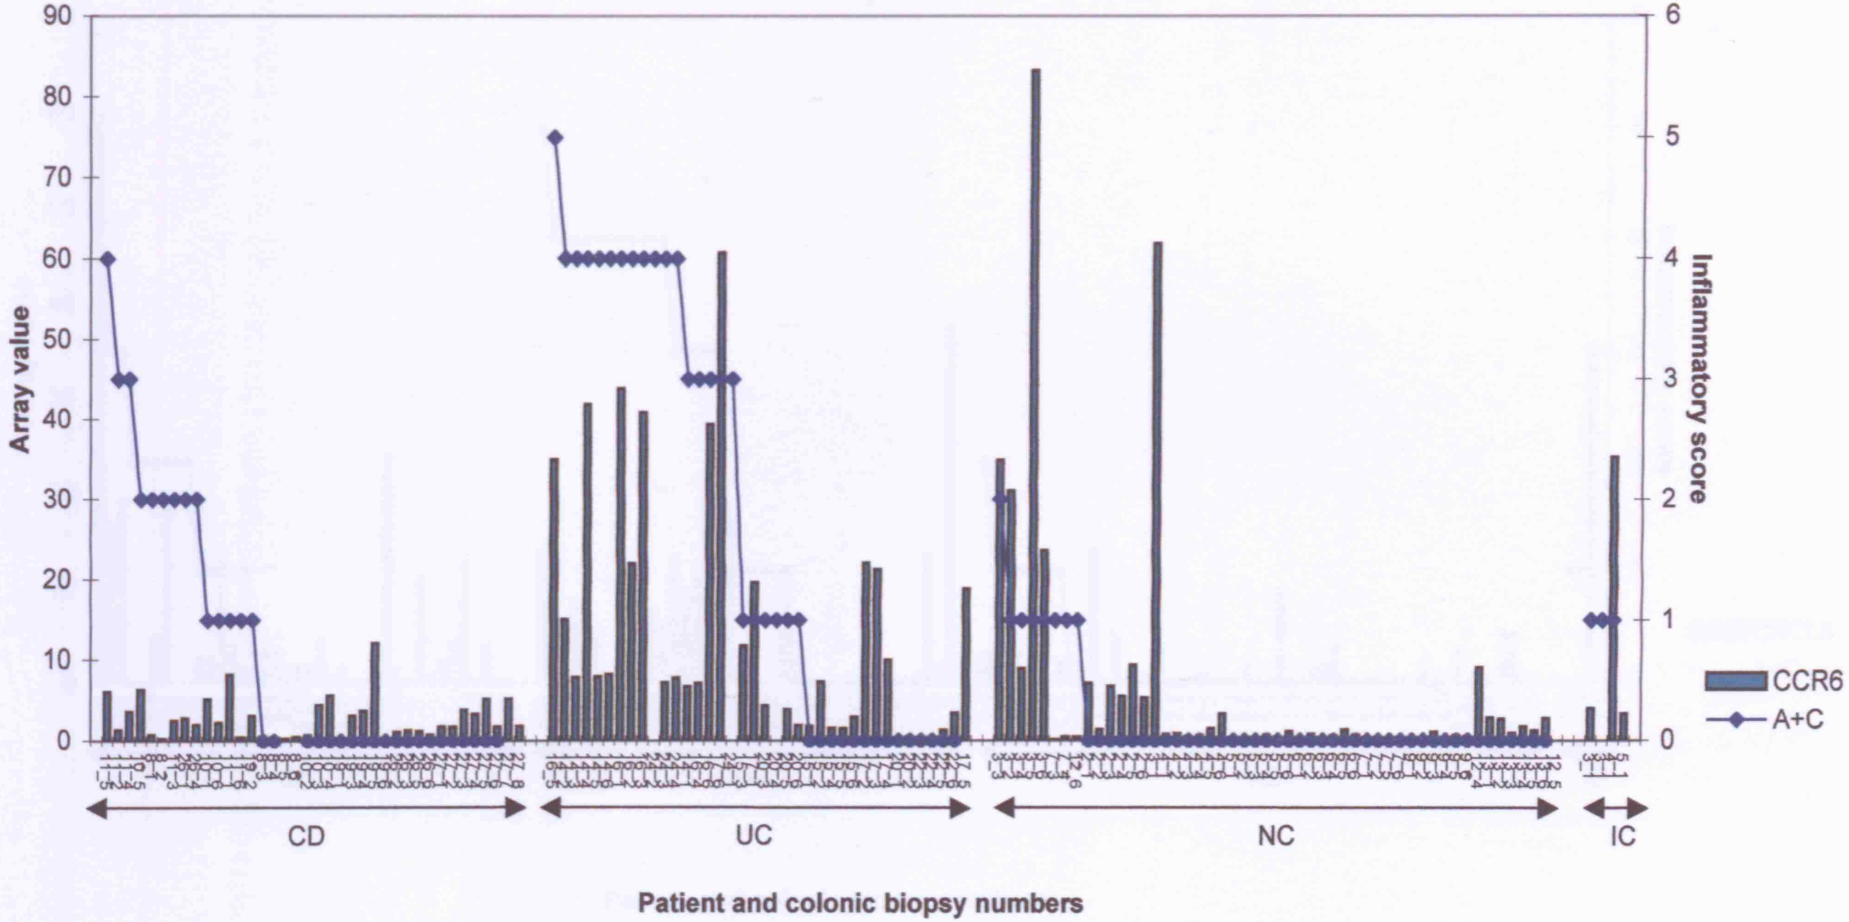
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.1). Patient and colonic biopsy details are outlined in appendix table 1. NC=normal control, IC=inflammatory control.

Graph 3.6: Relative expression of CCL20 in colonic biopsies measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



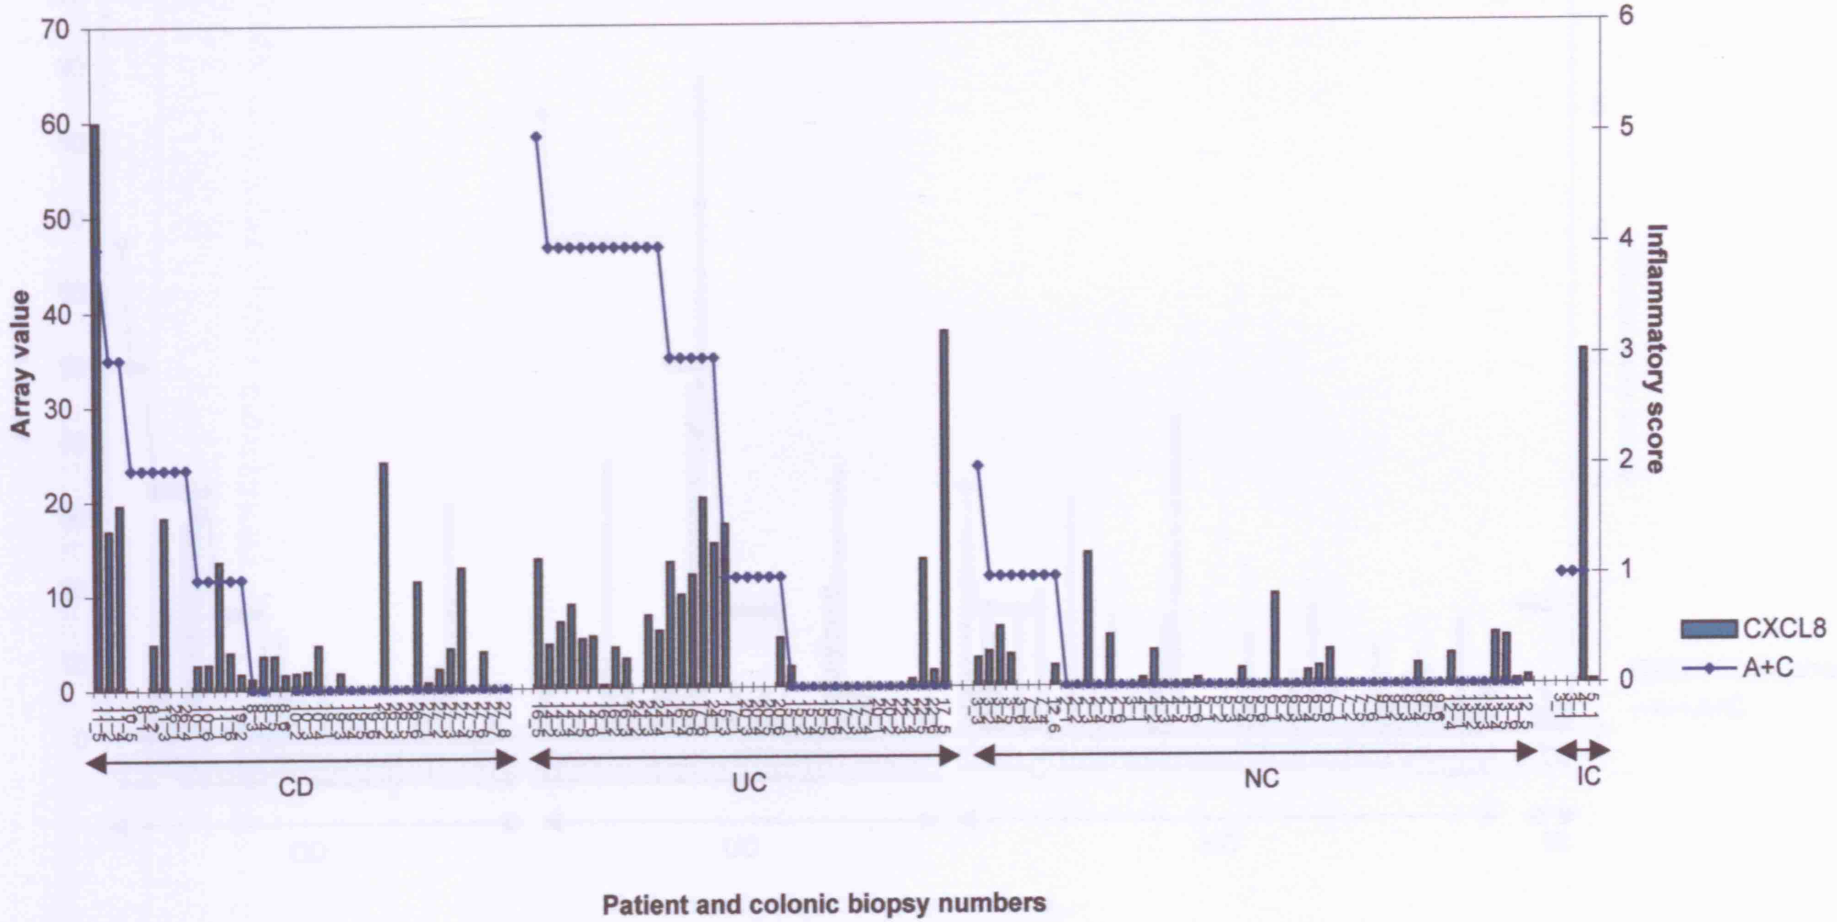
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.1). Patient and colonic biopsy details are outlined in appendix table 1. NC=normal control, IC=inflammatory control.

Graph 3.7: Relative expression of CCR6 in colonic biopsies measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



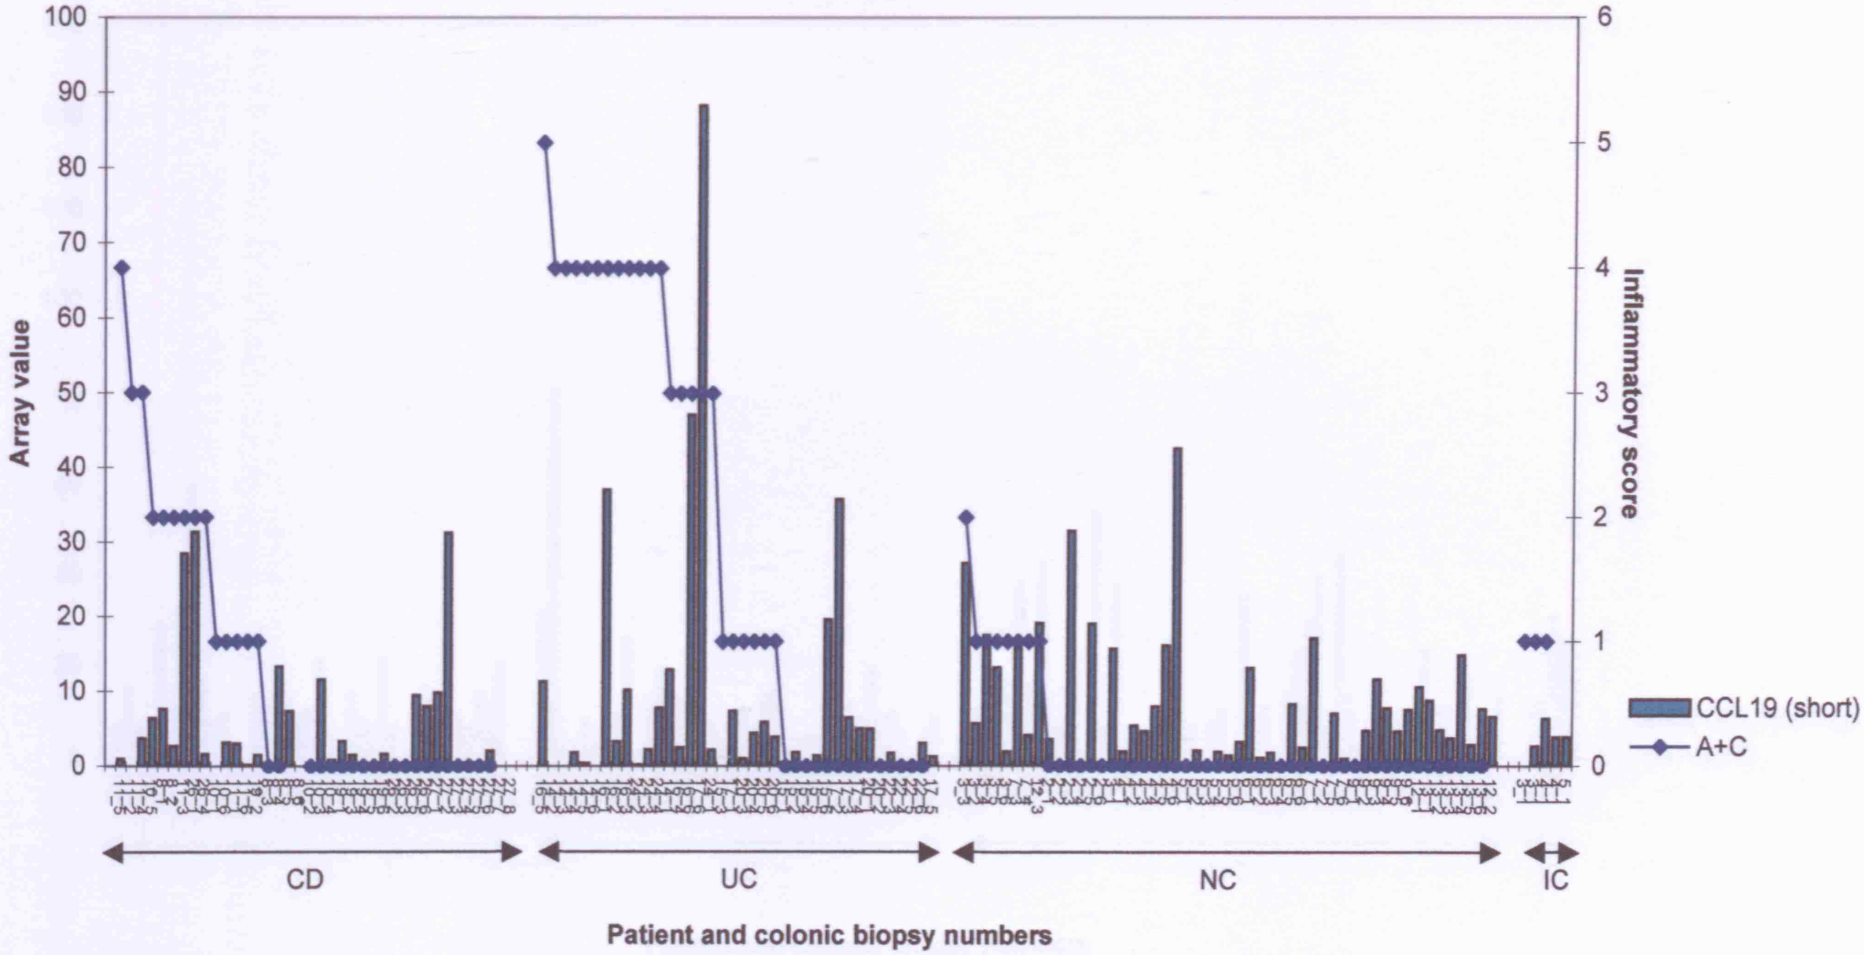
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.1). Patient and colonic biopsy details are outlined in appendix table 1. NC=normal control, IC=inflammatory control.

Graph 3.8: Relative expression of CXCL8 in colonic biopsies measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



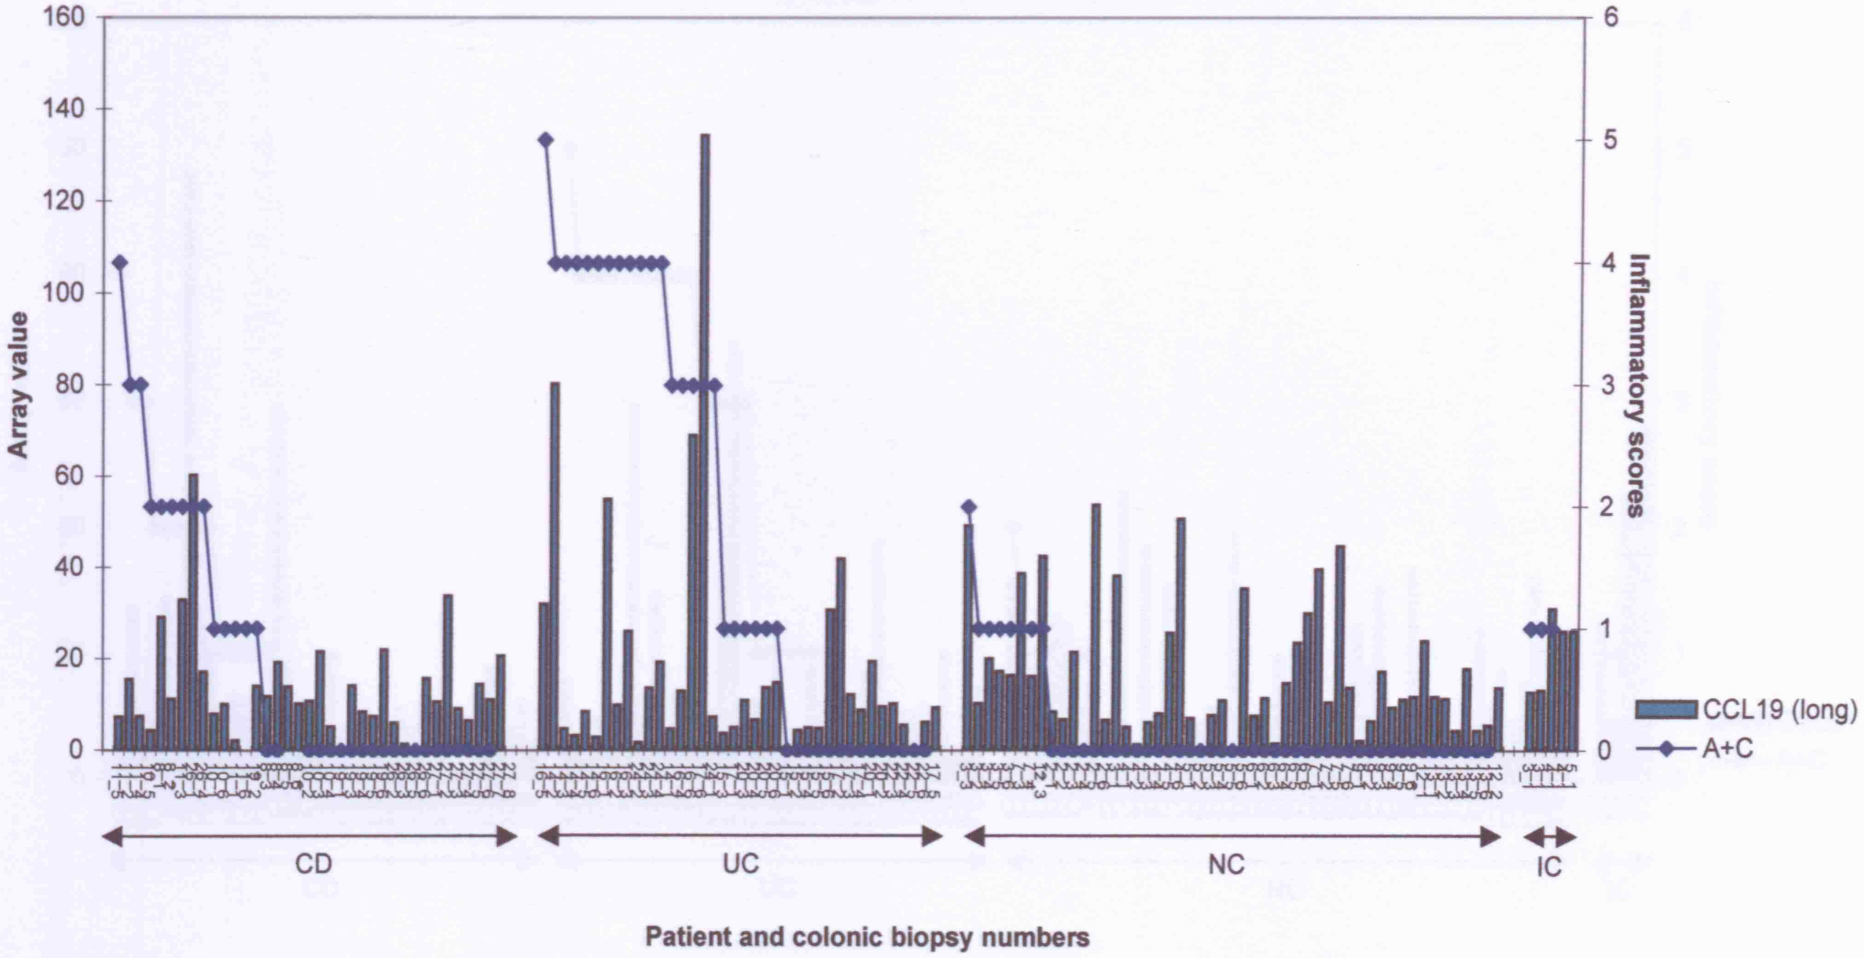
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and colonic biopsy details are outlined in appendix table 1. NC=normal control, IC=inflammatory control.

Graph 3.9: Relative expression of CCL19 (short arm) in colonic biopsies measured using microarray correlated with relative levels of inflammation as determined by histopathologocal analysis



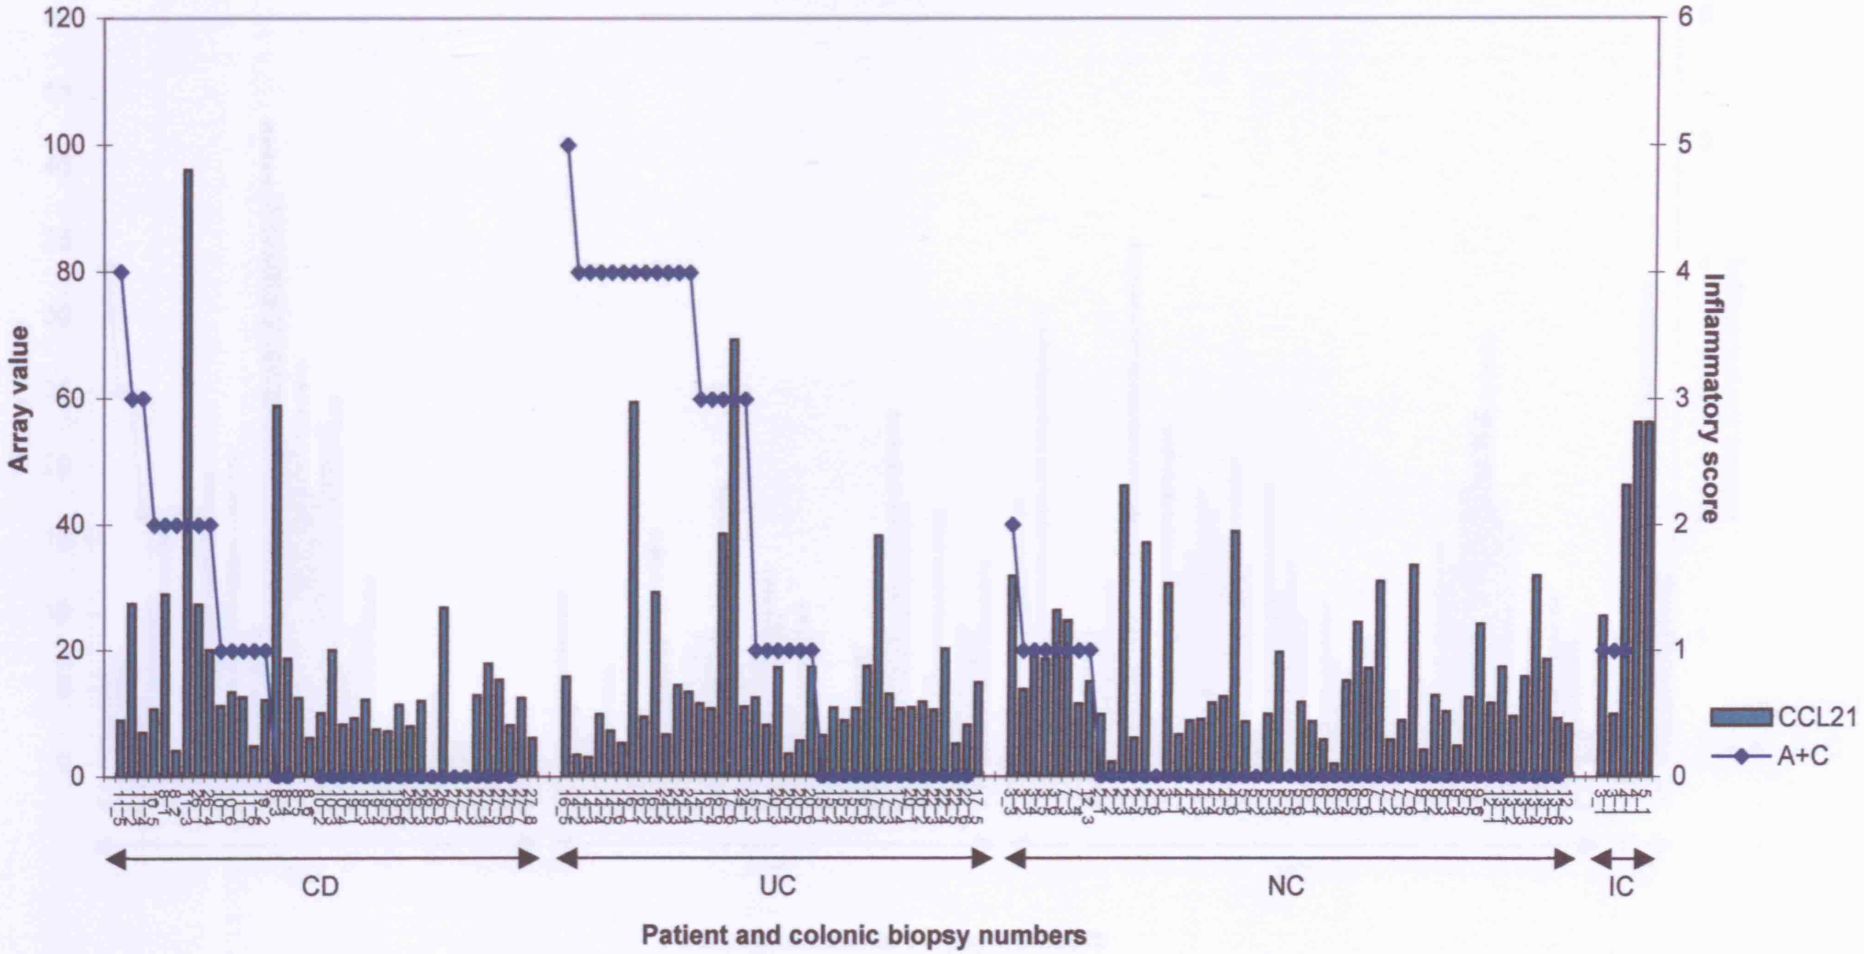
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.1). Patient and colonic biopsy details are outlined in appendix table 1. NC=normal control, IC=inflammatory control.

Graph 3.10: Relative expression of CCL19 (long arm) in colonic biopsies measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



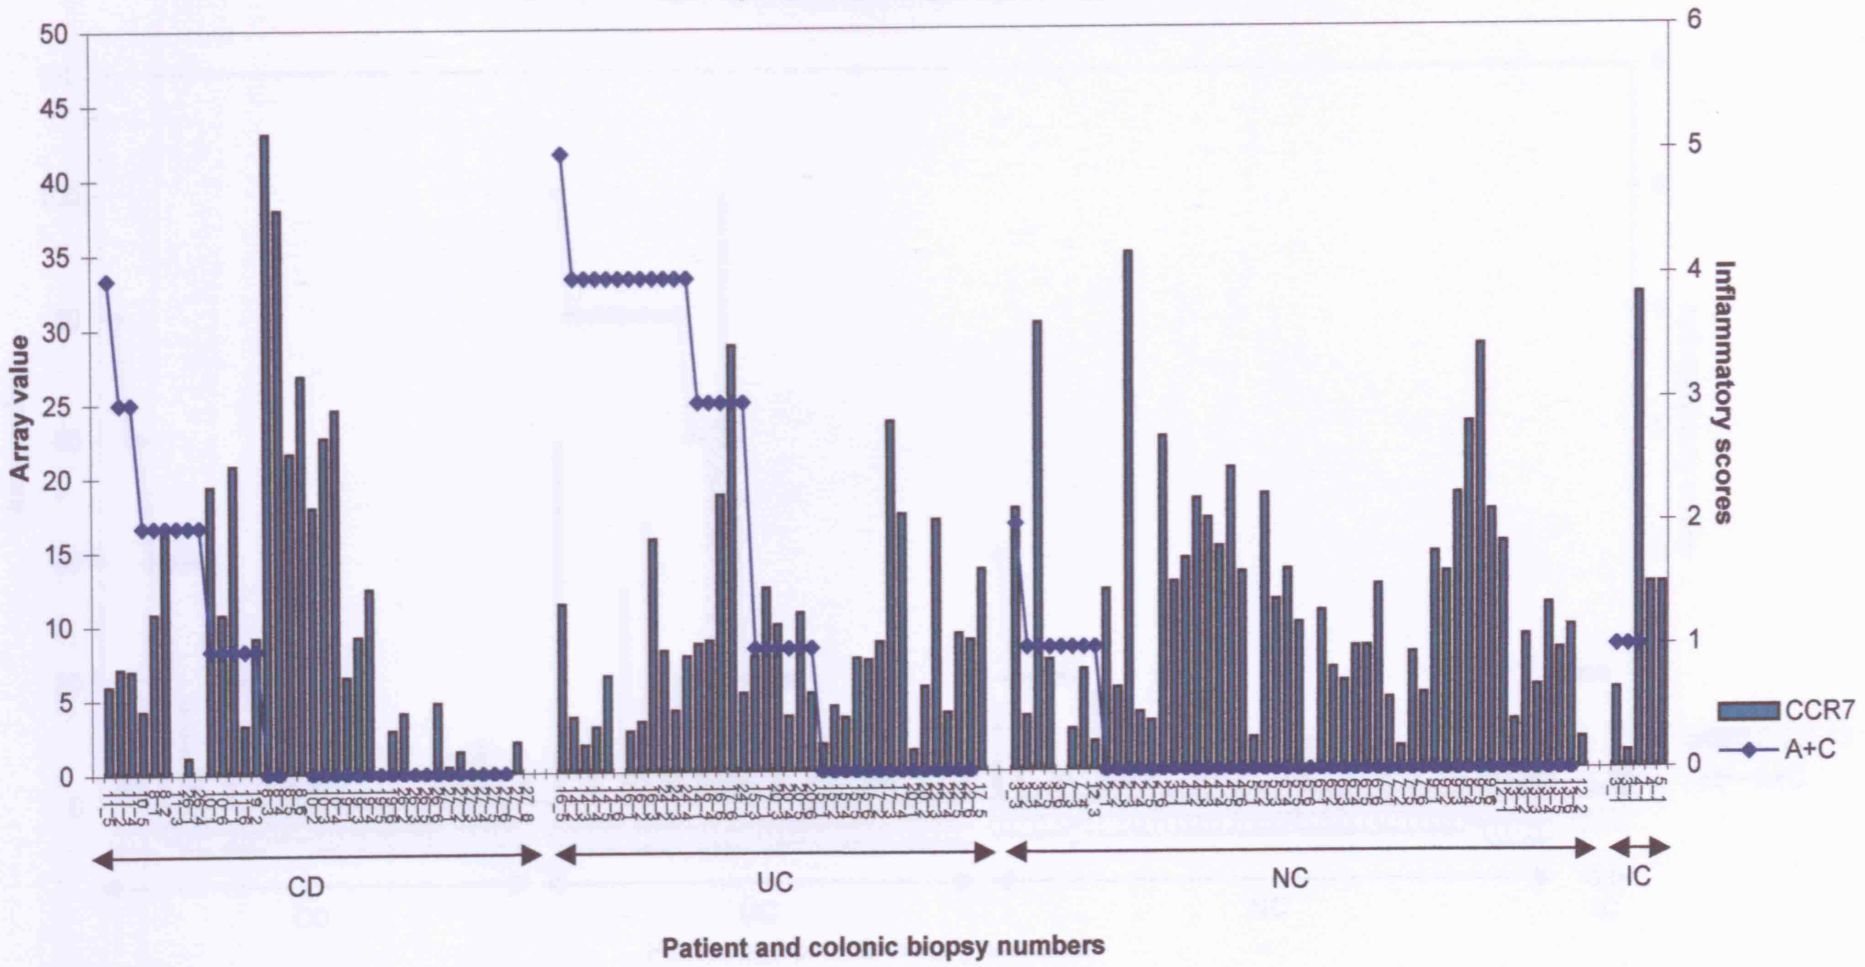
Patients are grouped according to disease, and chronologically placed according to inflammtory scores A+C (as defined in table 2.1). Patients and colonic biopsy details are outlined in appendix table 1. NC=normal control, IC=inflammatory control.

Graph 3.11: Relative expression of CCL21 in colonic biopsies measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



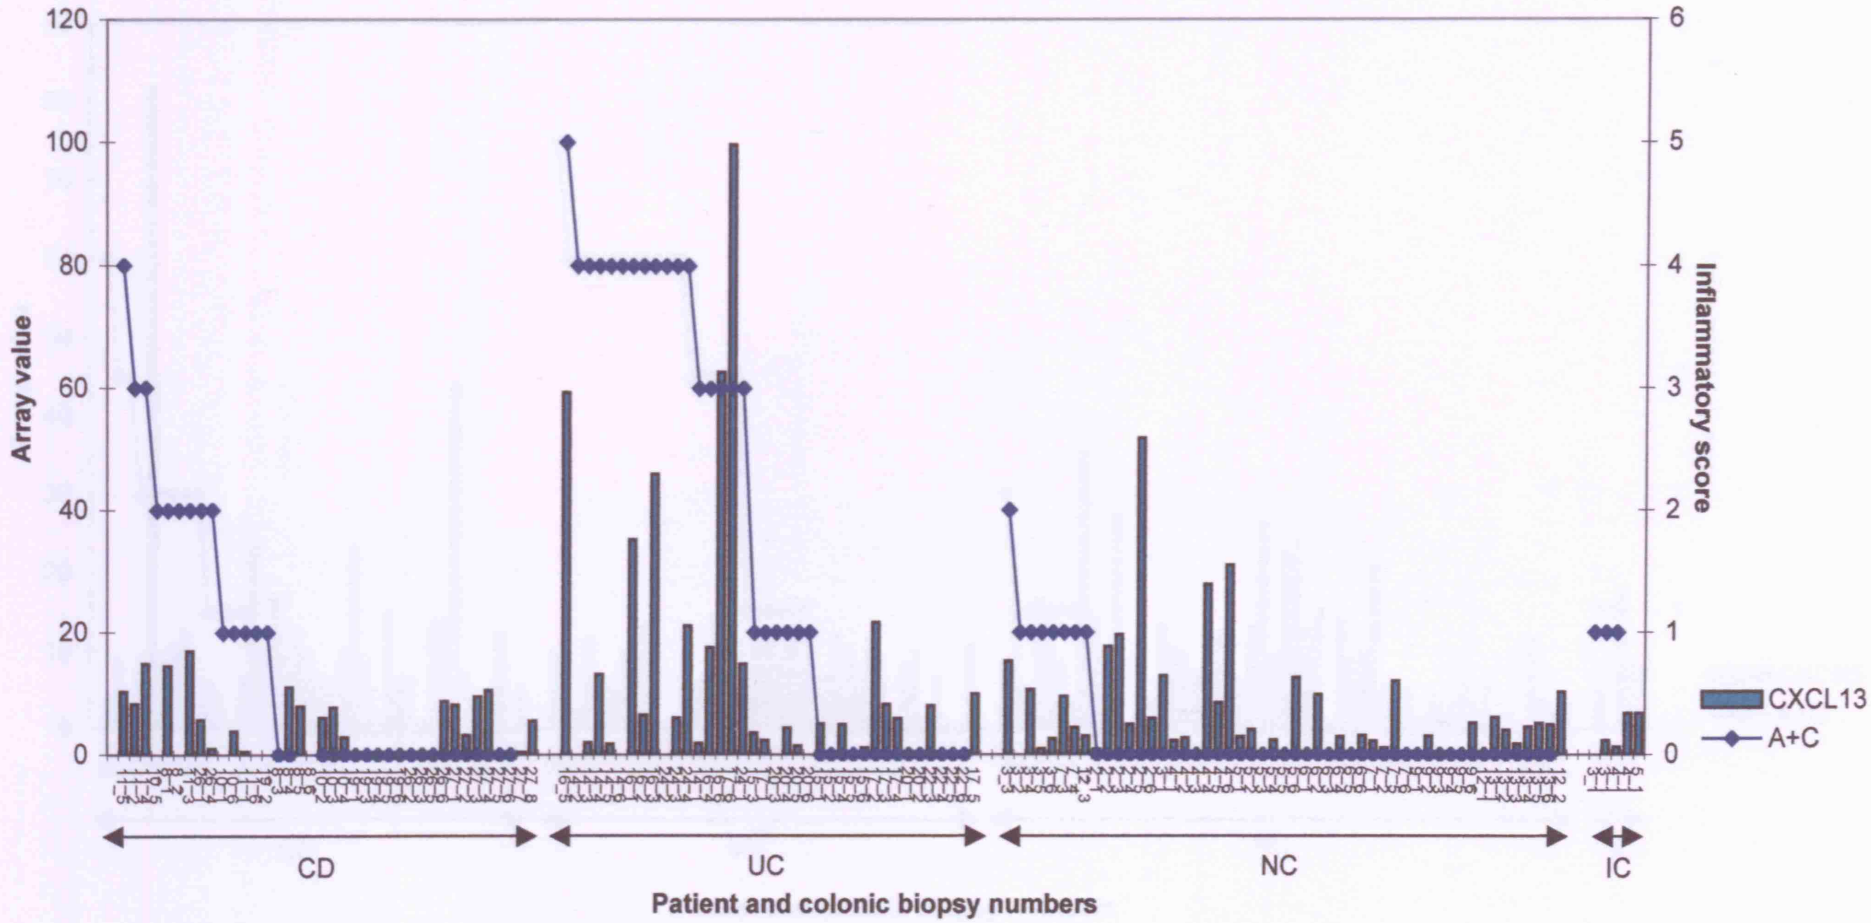
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.1). Patients and colonic biopsy details are outlined in appendix table 1. NC=normal control, IC=inflammatory control.

Graph 3.12: Relative expression of CCR7 in colonic biopsies measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



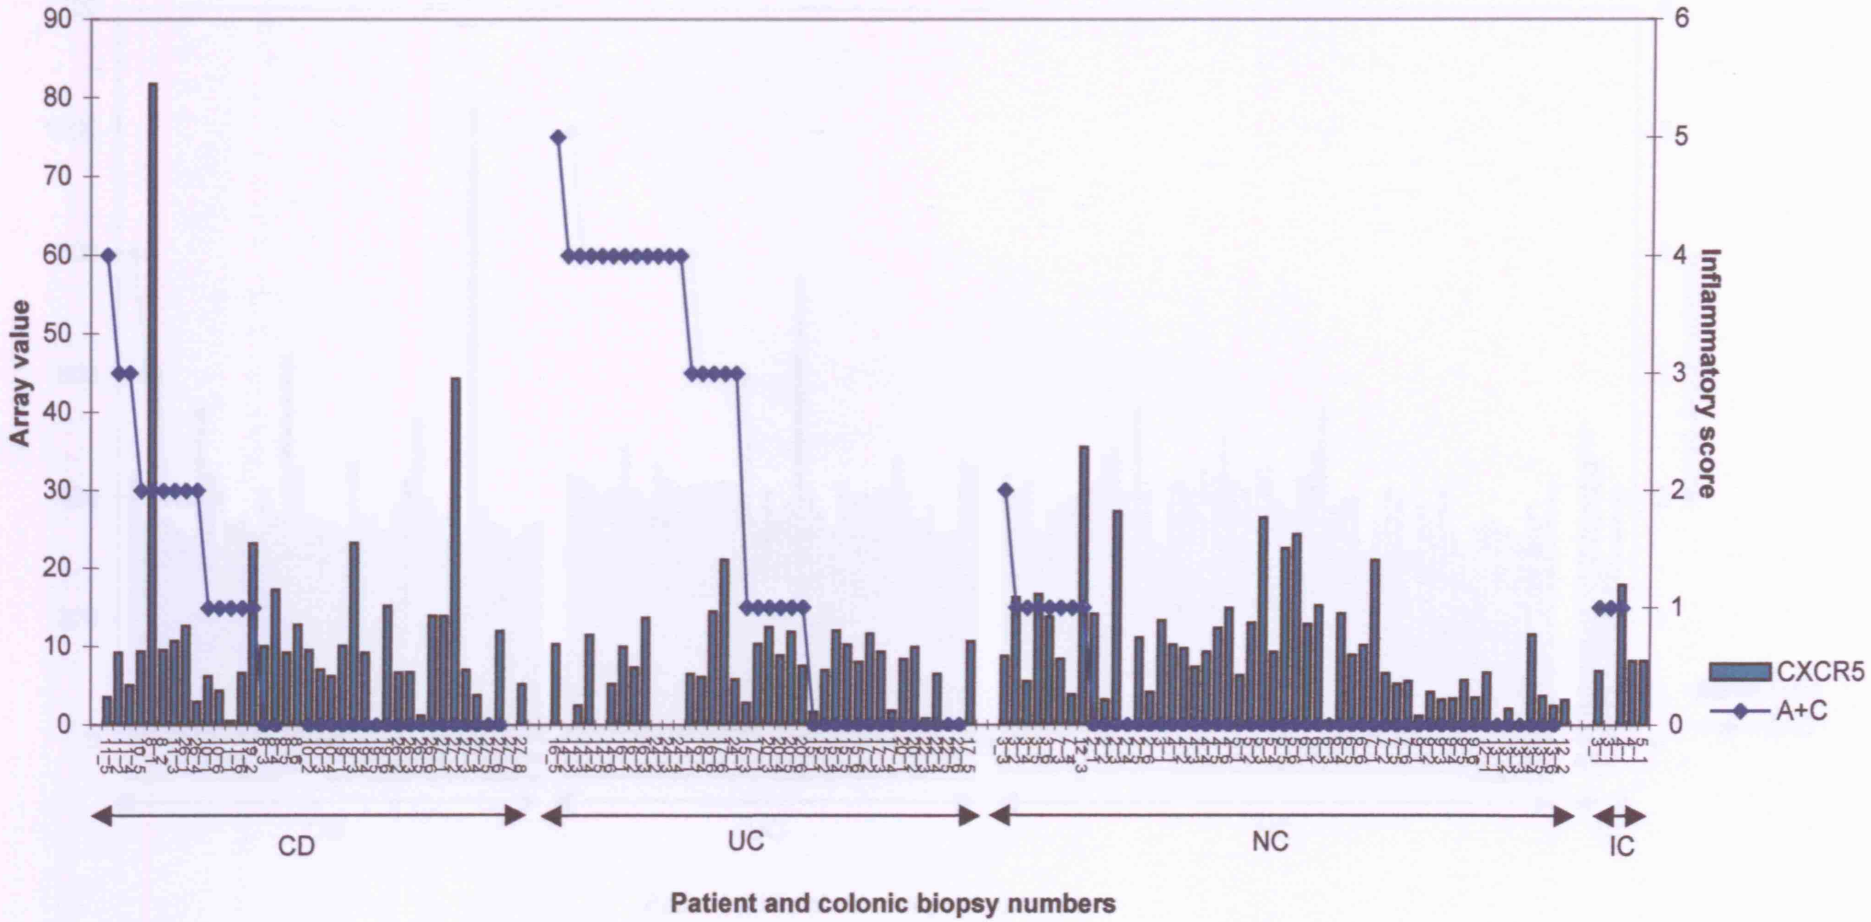
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.1). Patient and colonic biopsy details are outlined in appendix table 1. NC=normal control, IC=inflammatory control.

Graph 3.13: Relative expression of CXCL13 in colonic biopsies measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



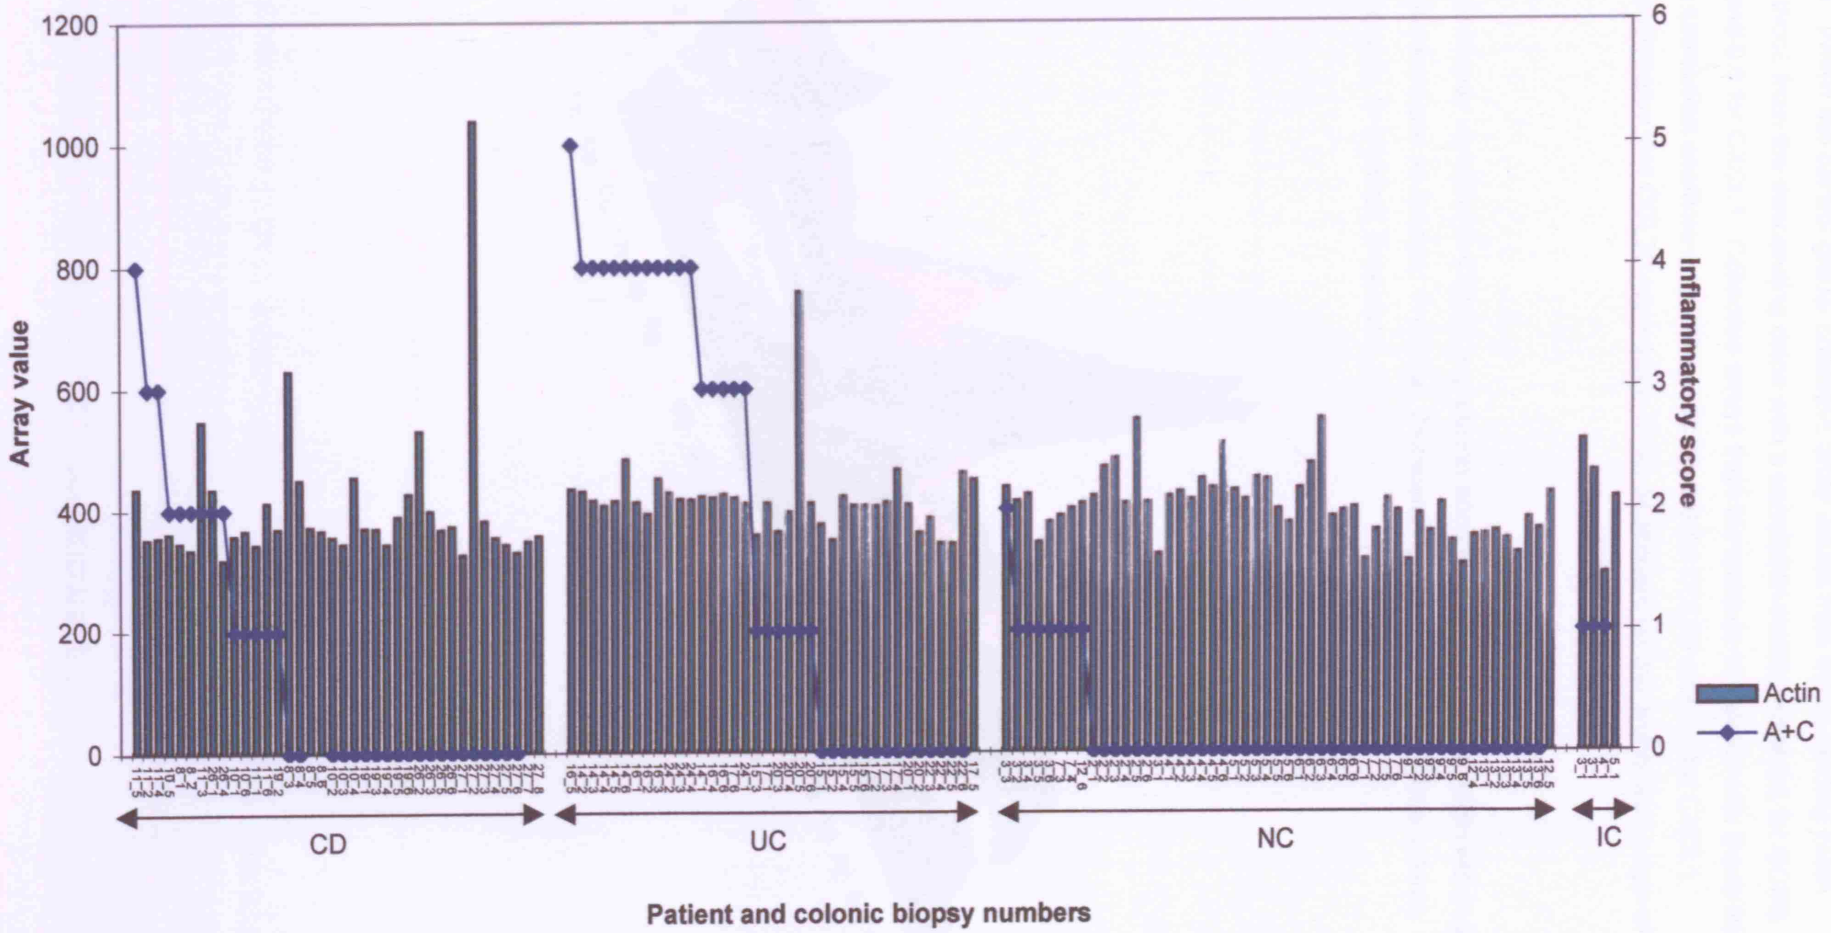
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.1). Patient and colonic biopsy details are outlined in appendix table 1. NC=normal control, IC=inflammatory control.

Graph 3.14: Relative expression of CXCR5 in colonic biopsies measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.1). Patient and colonic biopsy details are outlined in appendix table 1. NC=normal control, IC=inflammatory control.

Graph 3.15: Relative expression of actin in colonic biopsies measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



Patients are grouped according to disease, and chronologically placed accoprding to inflammatory scores A+C (as defined in table 2.1). Patients and colonic biopsy details are outlined in appendix table 1. NC=normal control, IC=inflammatory control.

Any variation in chemokine expression is not dependent on the anatomical origin of the biopsy within the colon. Within the control group, collective array values from the ascending colon correlated with those from the descending colon with a correlation coefficient of 0.9 for CCR6, 0.8 for CCL20 and 0.6 for CXCL1. Collective arrays from the caecum correlated with those from the rectum with correlation coefficients of 0.9 for CCR6, 0.3 for CCL20 and 0.2 for CXCL1. Graph 3.16 demonstrates that CCL20 expression is not dependent on the anatomical origin of the biopsy.

Graph 3.16: Inter-biopsy variation in CCL20 expression according to anatomical origin within the colon. Biopsy numbers are as follows: 1=caecal, 2=ascending colonic, 3=transverse colonic, 4=descending colonic, 5=sigmoid, 6=rectal.

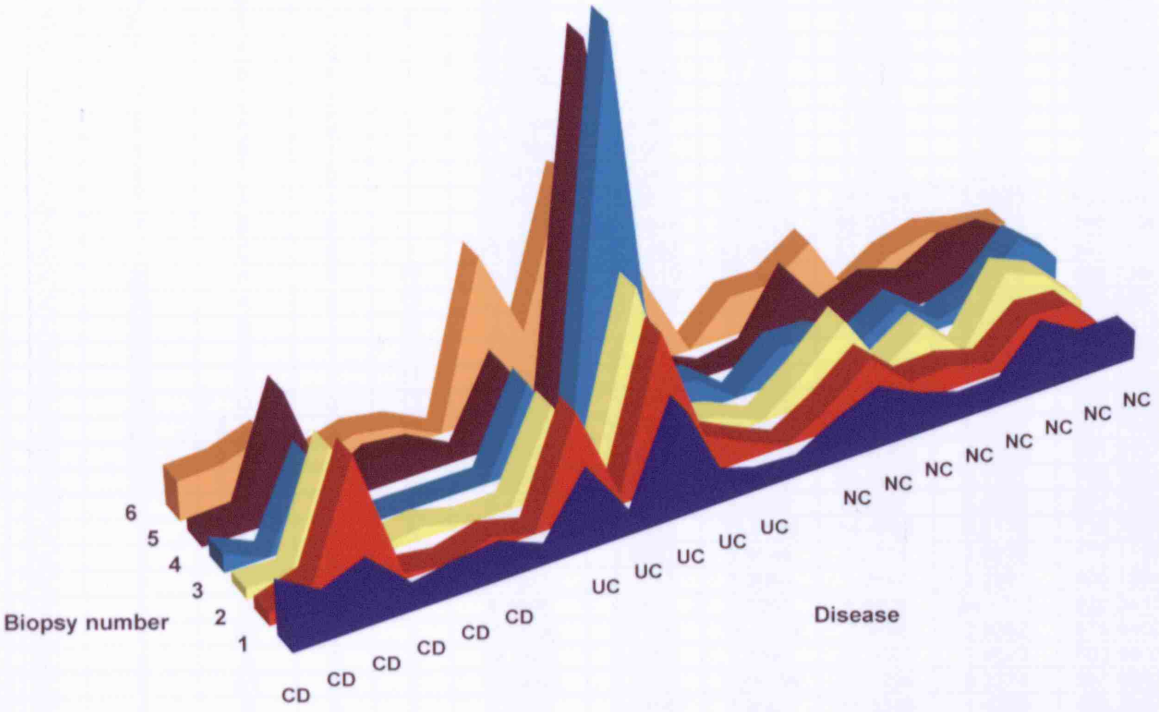


Table 3.5: Relative expression levels of CCR6, CXCL1, CXCL2, CXCL3, CCL20 and actin, obtained by semi-quantitative assessment of the microarray result from surgically obtained colonic tissue, with inflammatory quotients. Where the level is less than 10-15, the level is not significantly detected. NC=normal control, IC=inflammatory control, EP=epithelial, LP= lamina propria. The area corresponds to colonic area of tissue removed, as outlined in appendix 4.4.

Table 3.6: Relative expression levels of CCR7, CXCR5, CXCL13 and CCL19 obtained by semi-quantitative assessment of the microarray result from surgically obtained colonic tissue, with inflammatory quotients. Where the level is less than 10-15, the level is not significantly detected. NC=normal control, IC=inflammatory control, EP=epithelial, LP= lamina propria. The area corresponds to colonic area of tissue removed, as outlined in appendix 4.4.

Table 3.8: Relative expression levels of CCL2, CCL24, CXCR1, CXCR2, CXCR3, CCR3 and CCL3 obtained by semi-quantitative assessment of the microarray result from surgically obtained colonic tissue, with inflammatory quotients. Where the level is less than 10-15, the level is not significantly detected. NC=normal control, IC=inflammatory control, EP=epithelial, LP= lamina propria. The area corresponds to colonic area of tissue removed, as outlined in appendix 4.4.

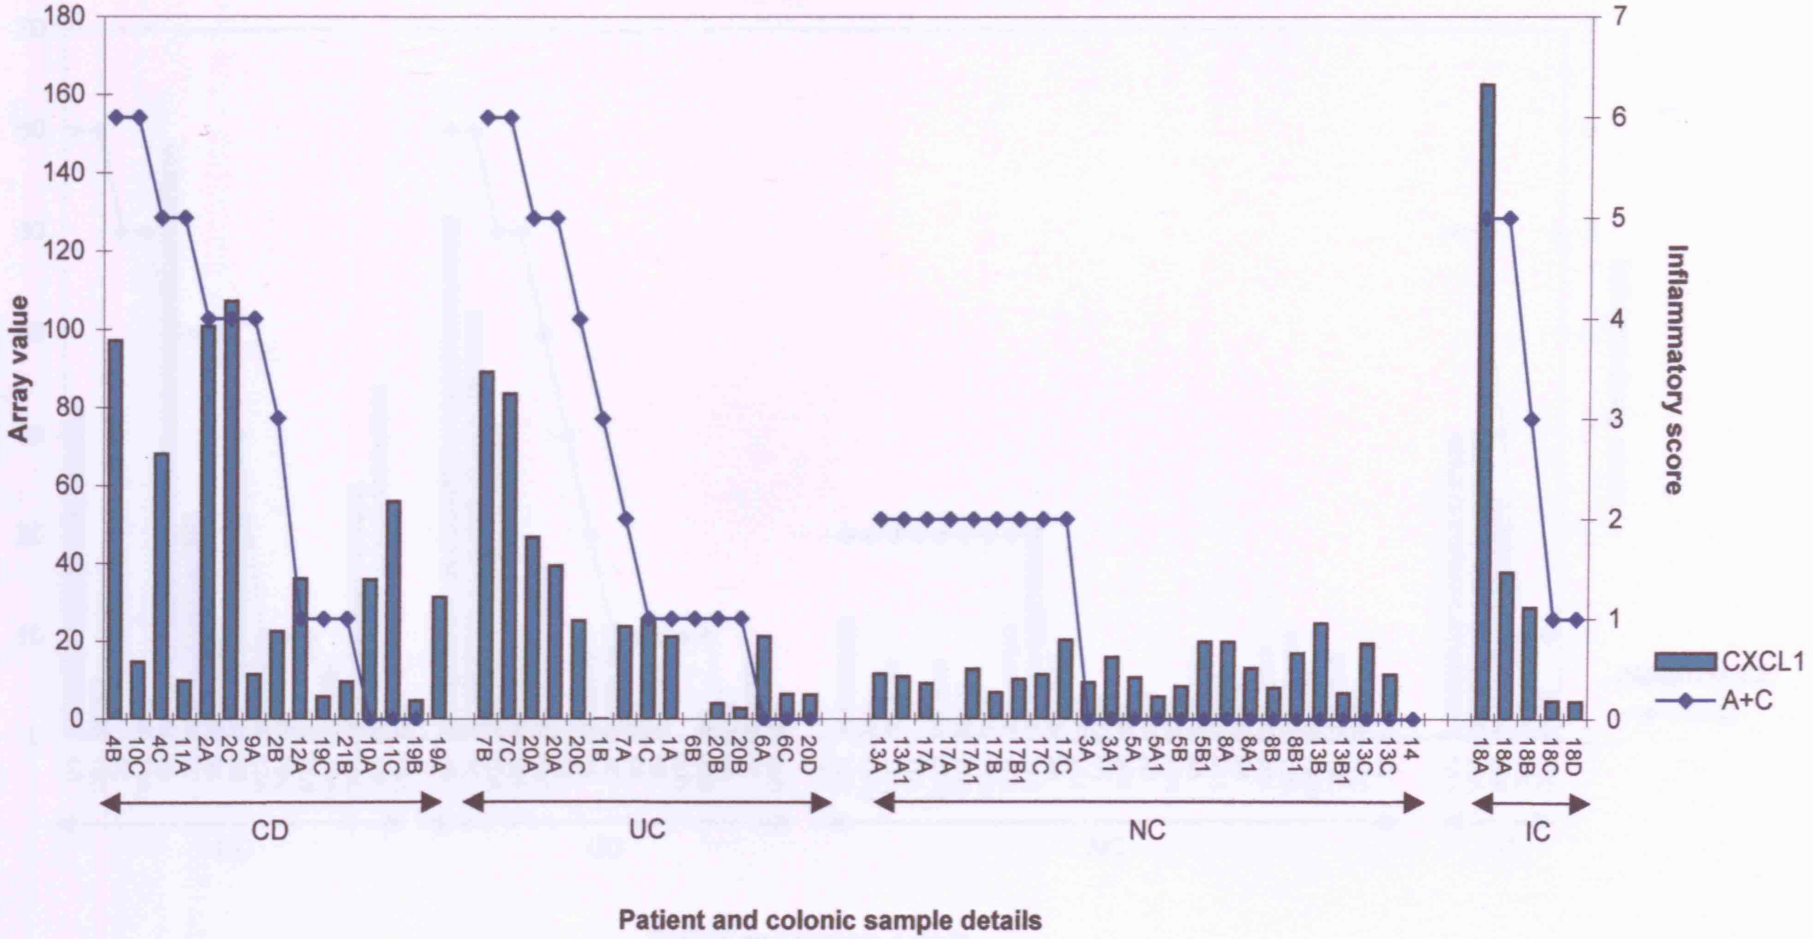
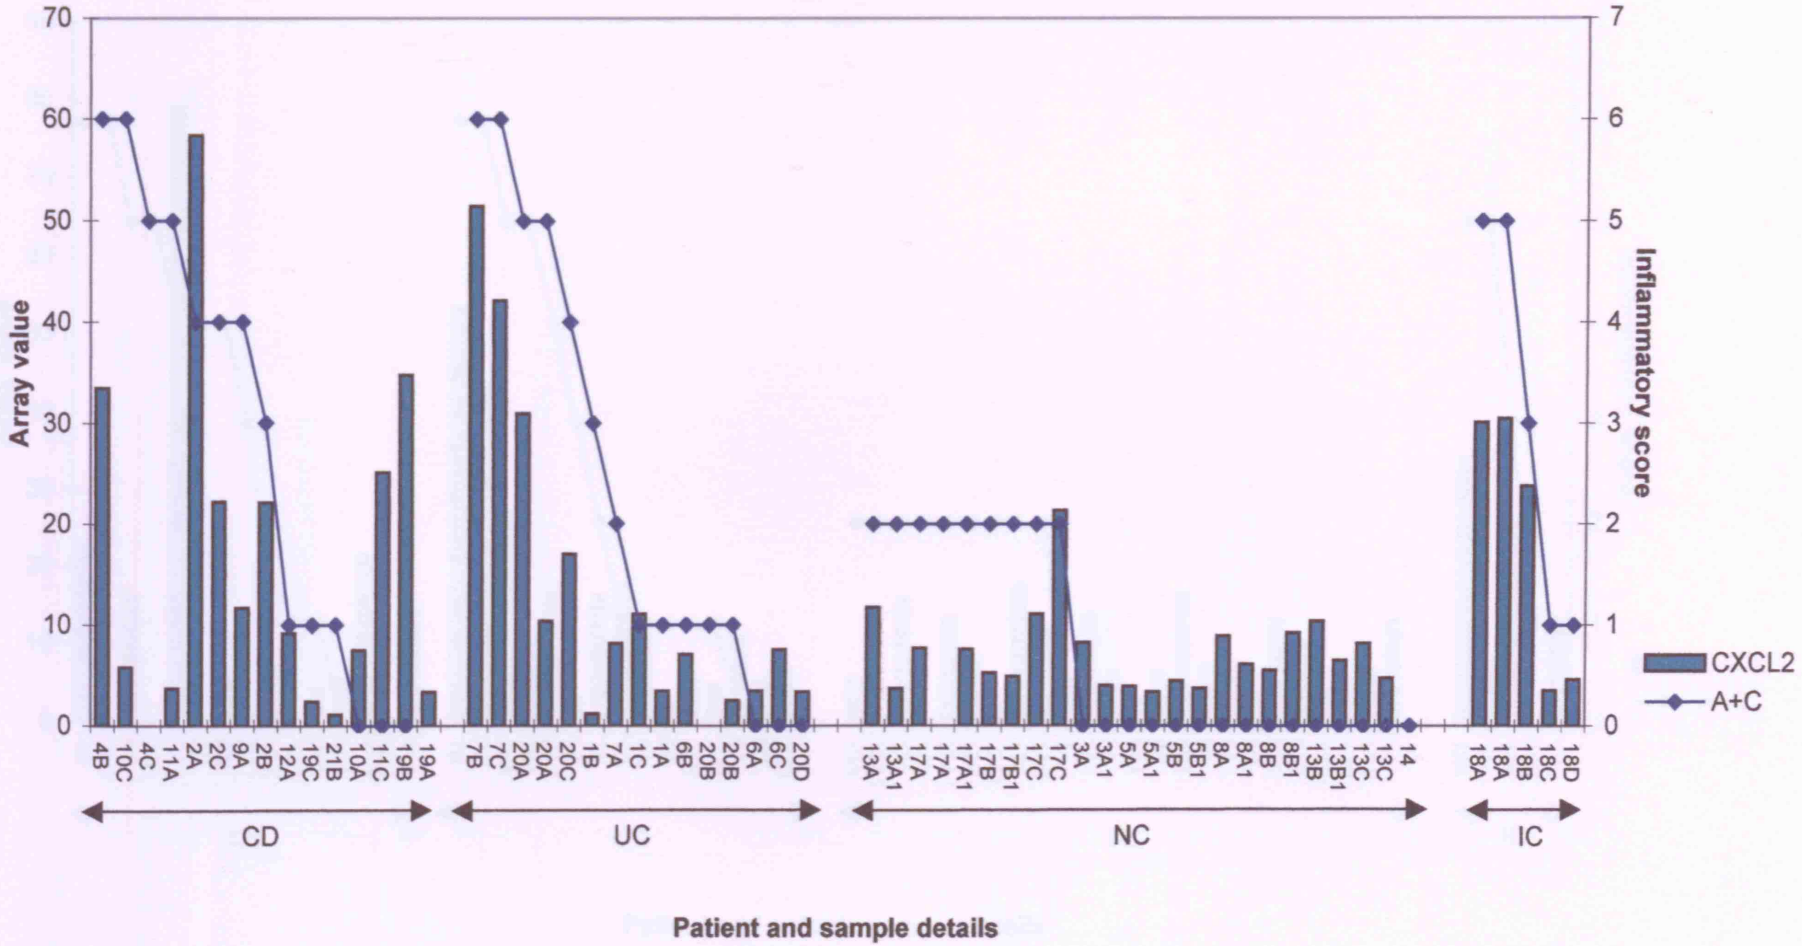
Graph 3.17: Relative expression of CXCL1 in full thickness colonic tissue measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



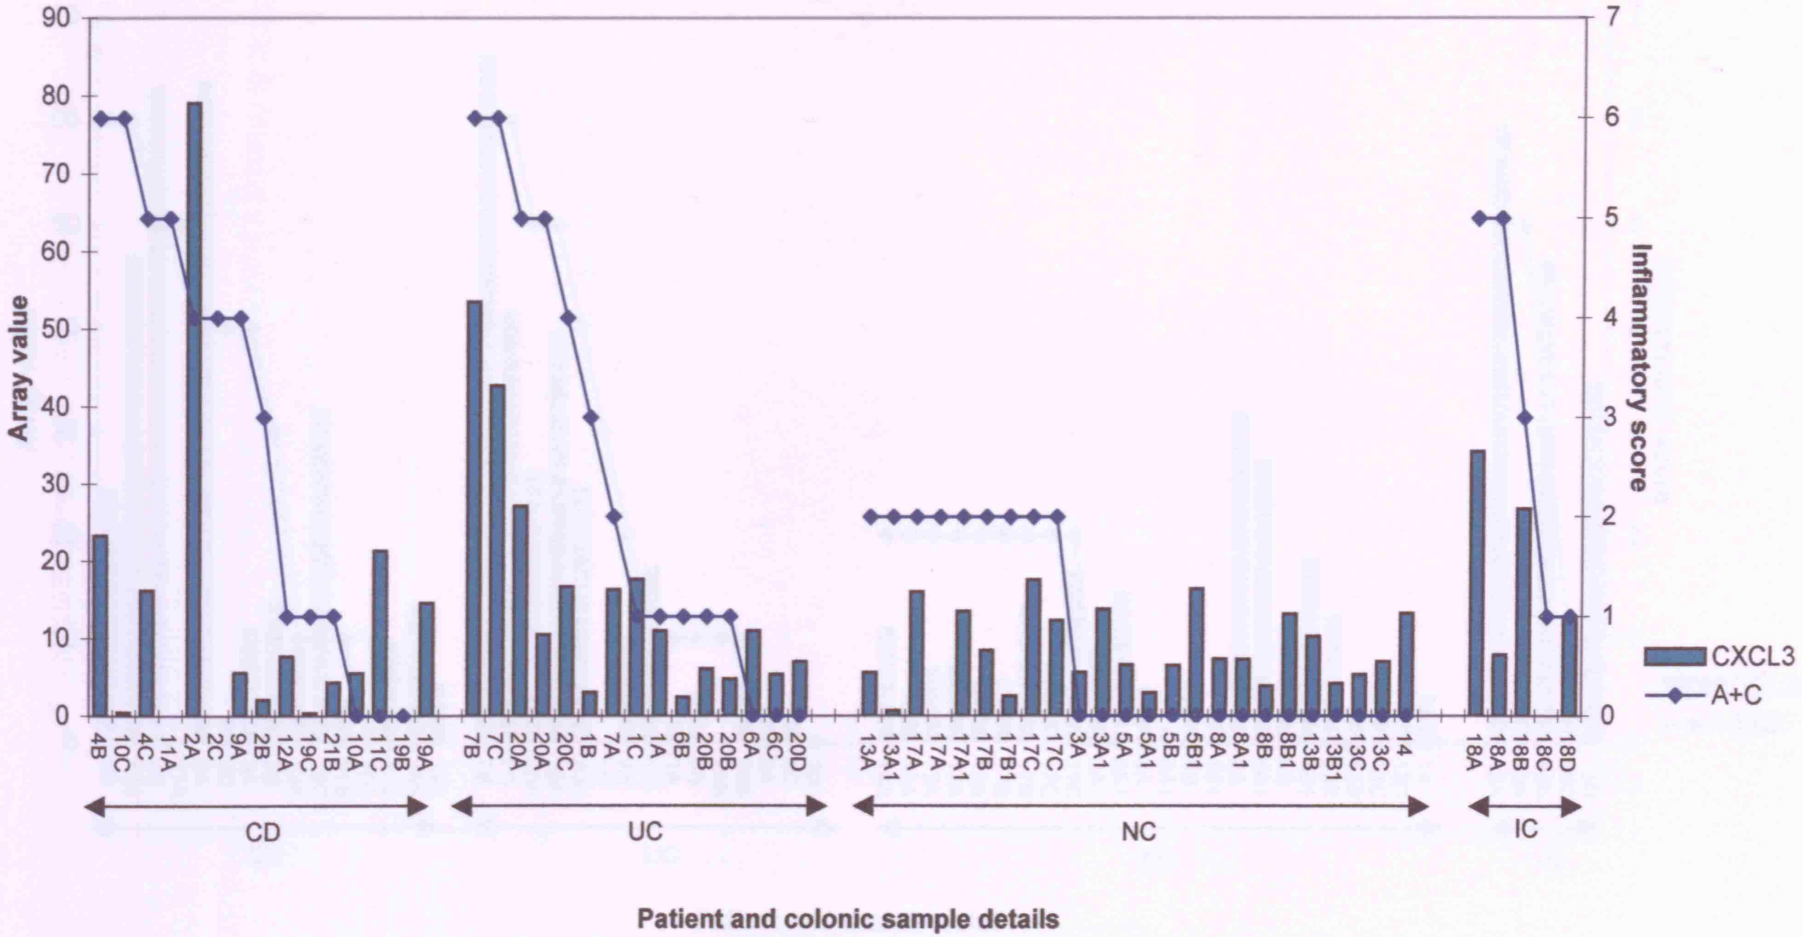
Patients are grouped according to disease, and chronologically placed according inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammatory control.

Graph 3.18: Relative expression levels of CXCL2 in full-thickness colonic tissue measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



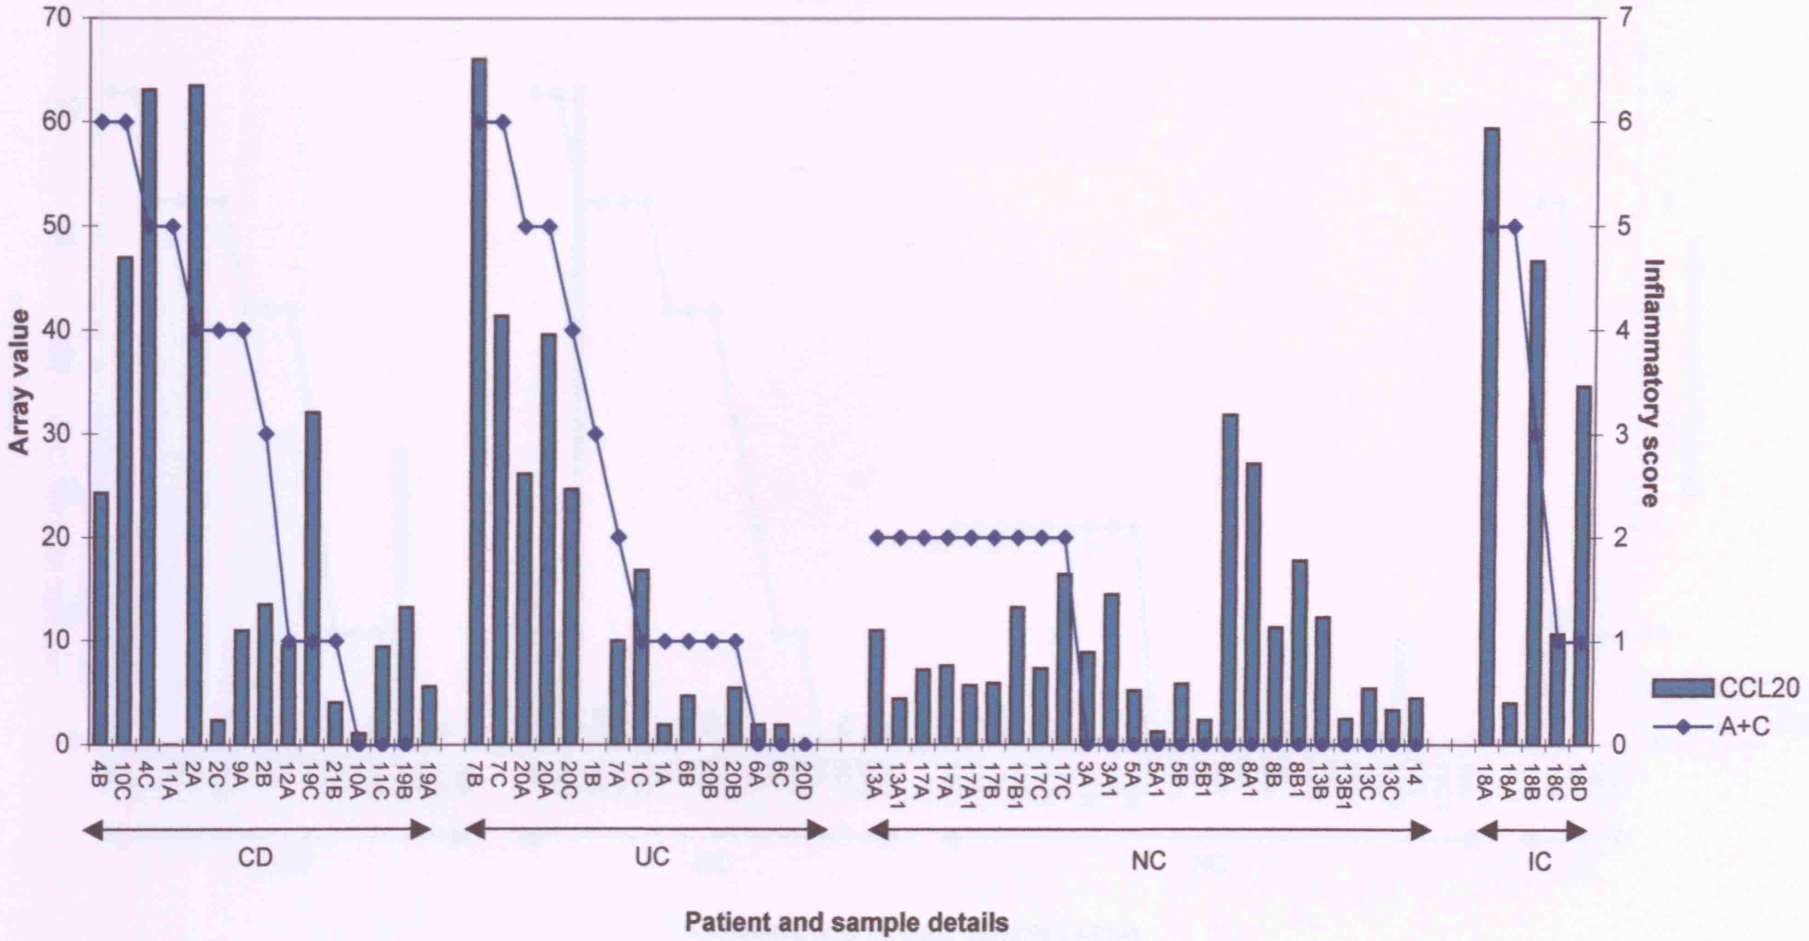
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammatory control.

Graph 3.19: Relative expression of CXCL3 in full thickness colonic tissue measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



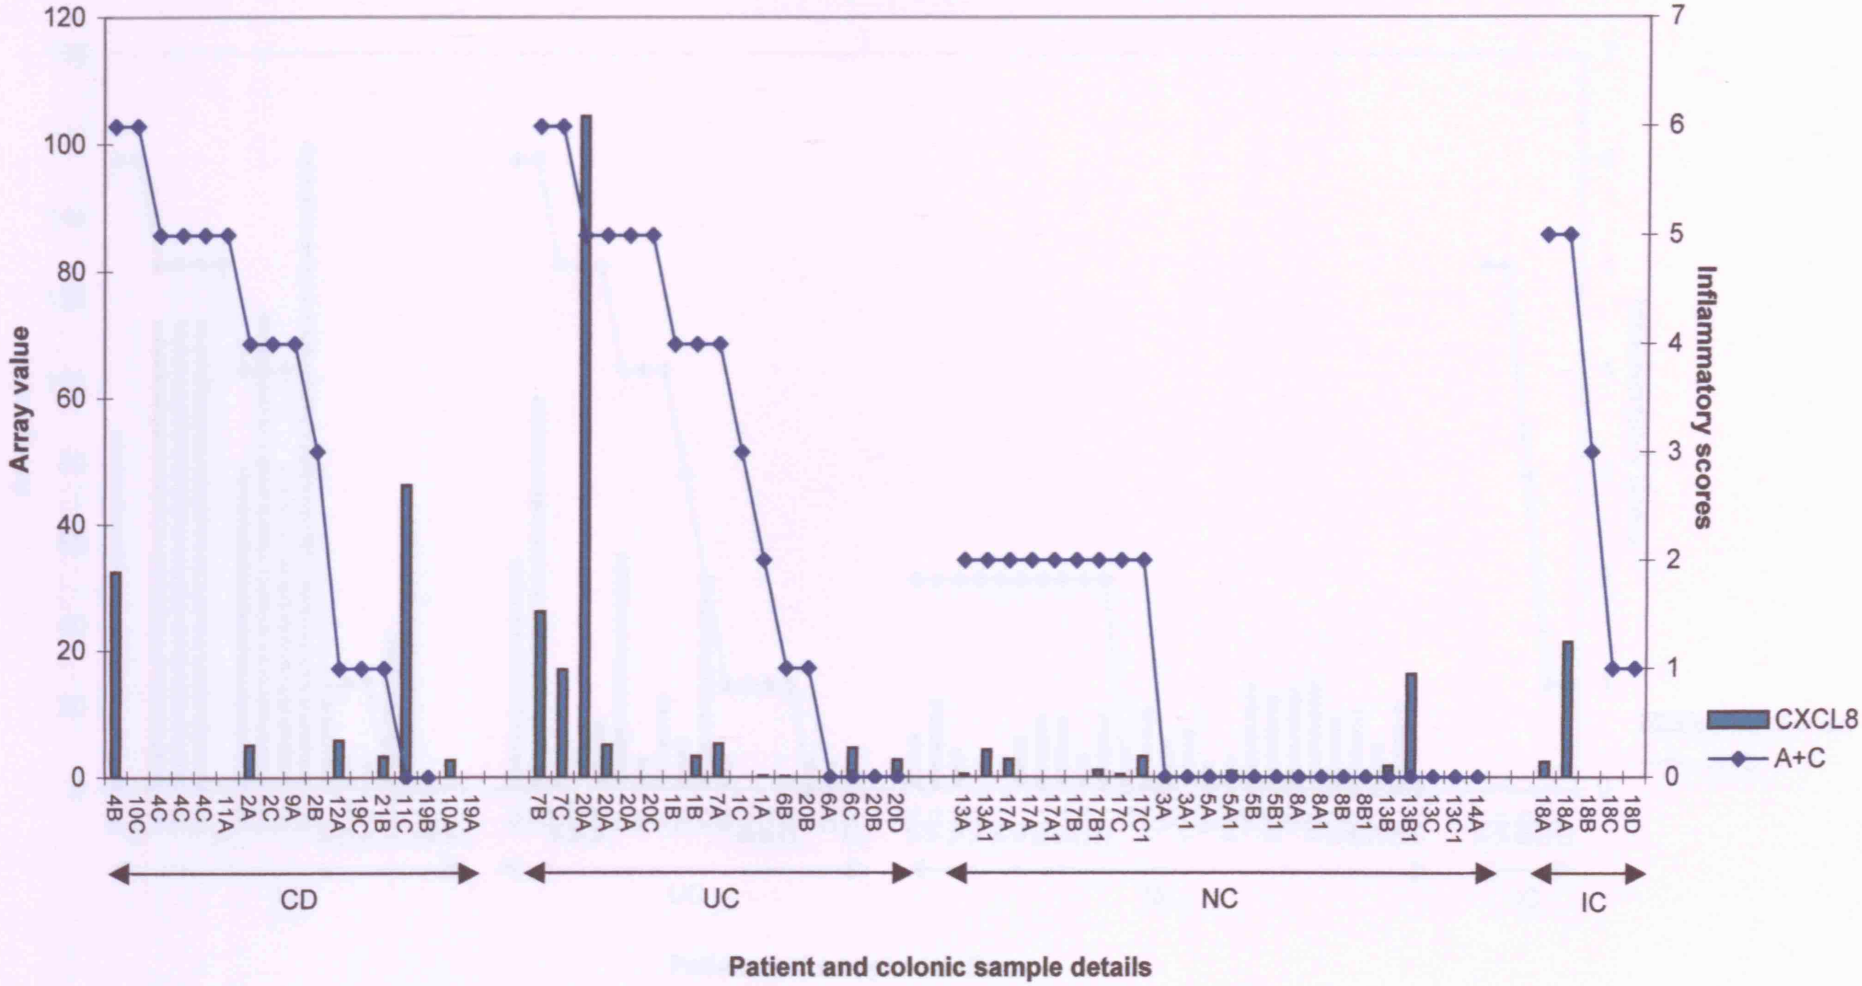
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflmmatory control.

Graph 3.20: Relative expression levels of CCL20 in full-thickness colonic tissue measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



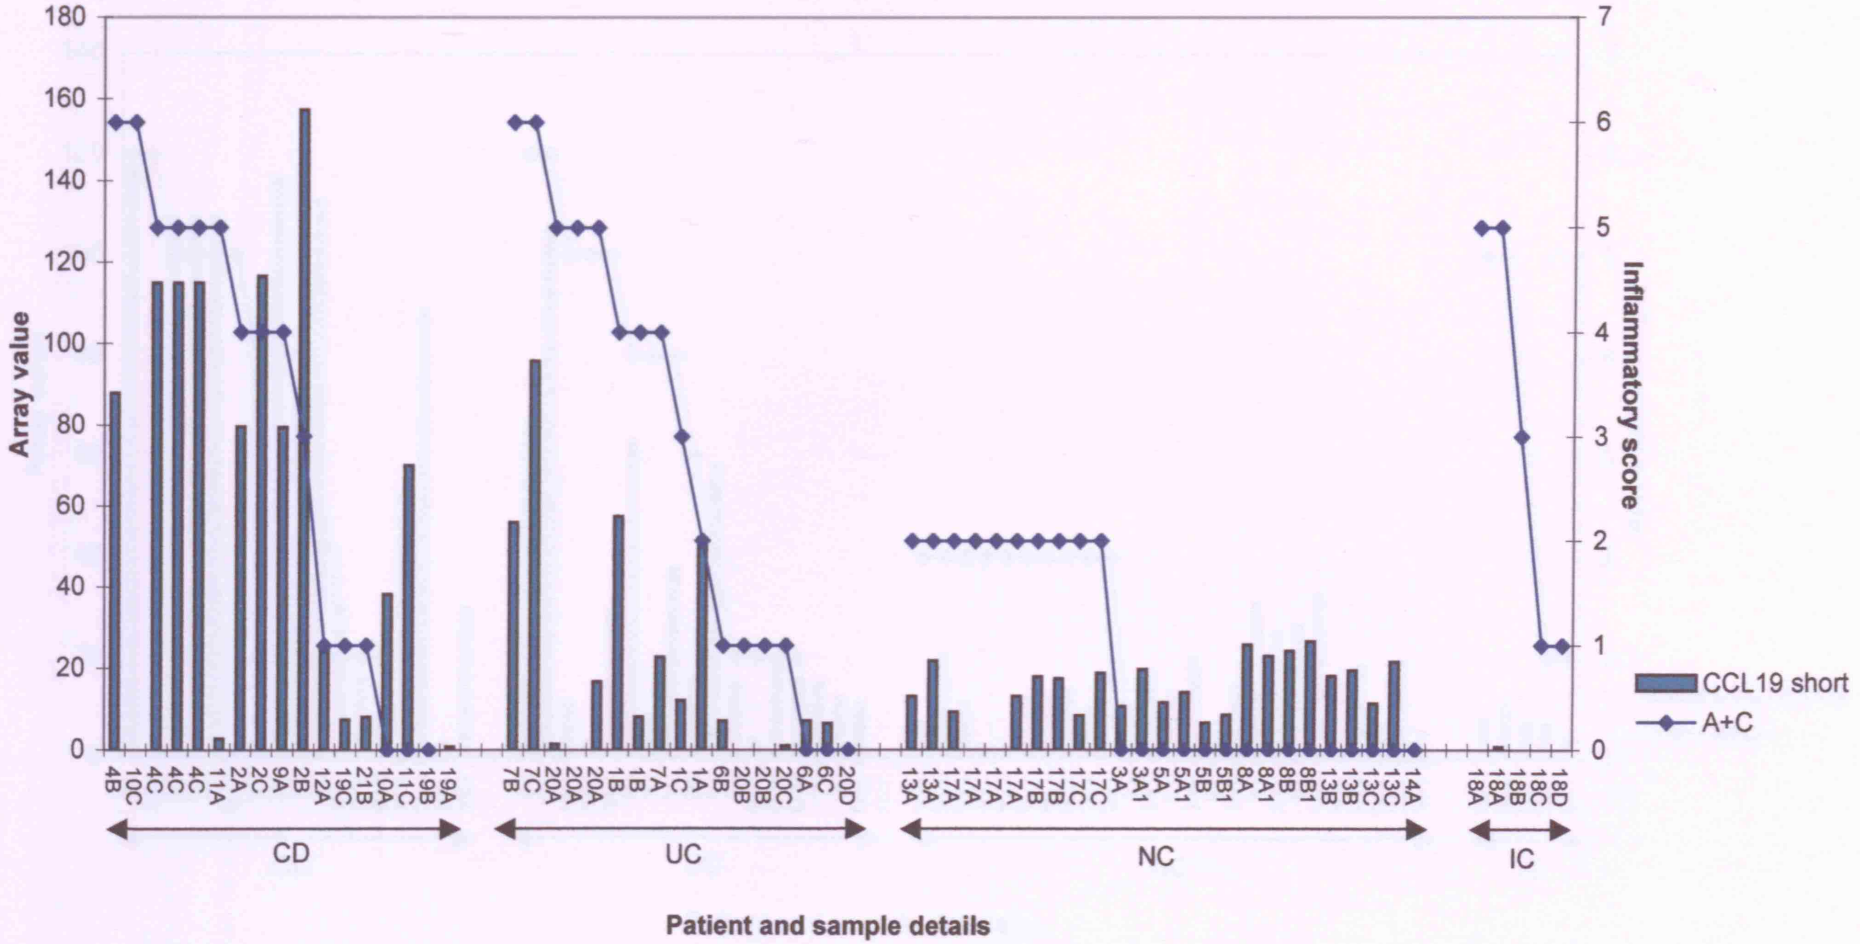
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patients and sample details are outlined in appendix 2. NC=normal control, IC=inflammtory control.

Graph 3.21: Relative expression of CXCL8 in full thickness colonic tissue measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



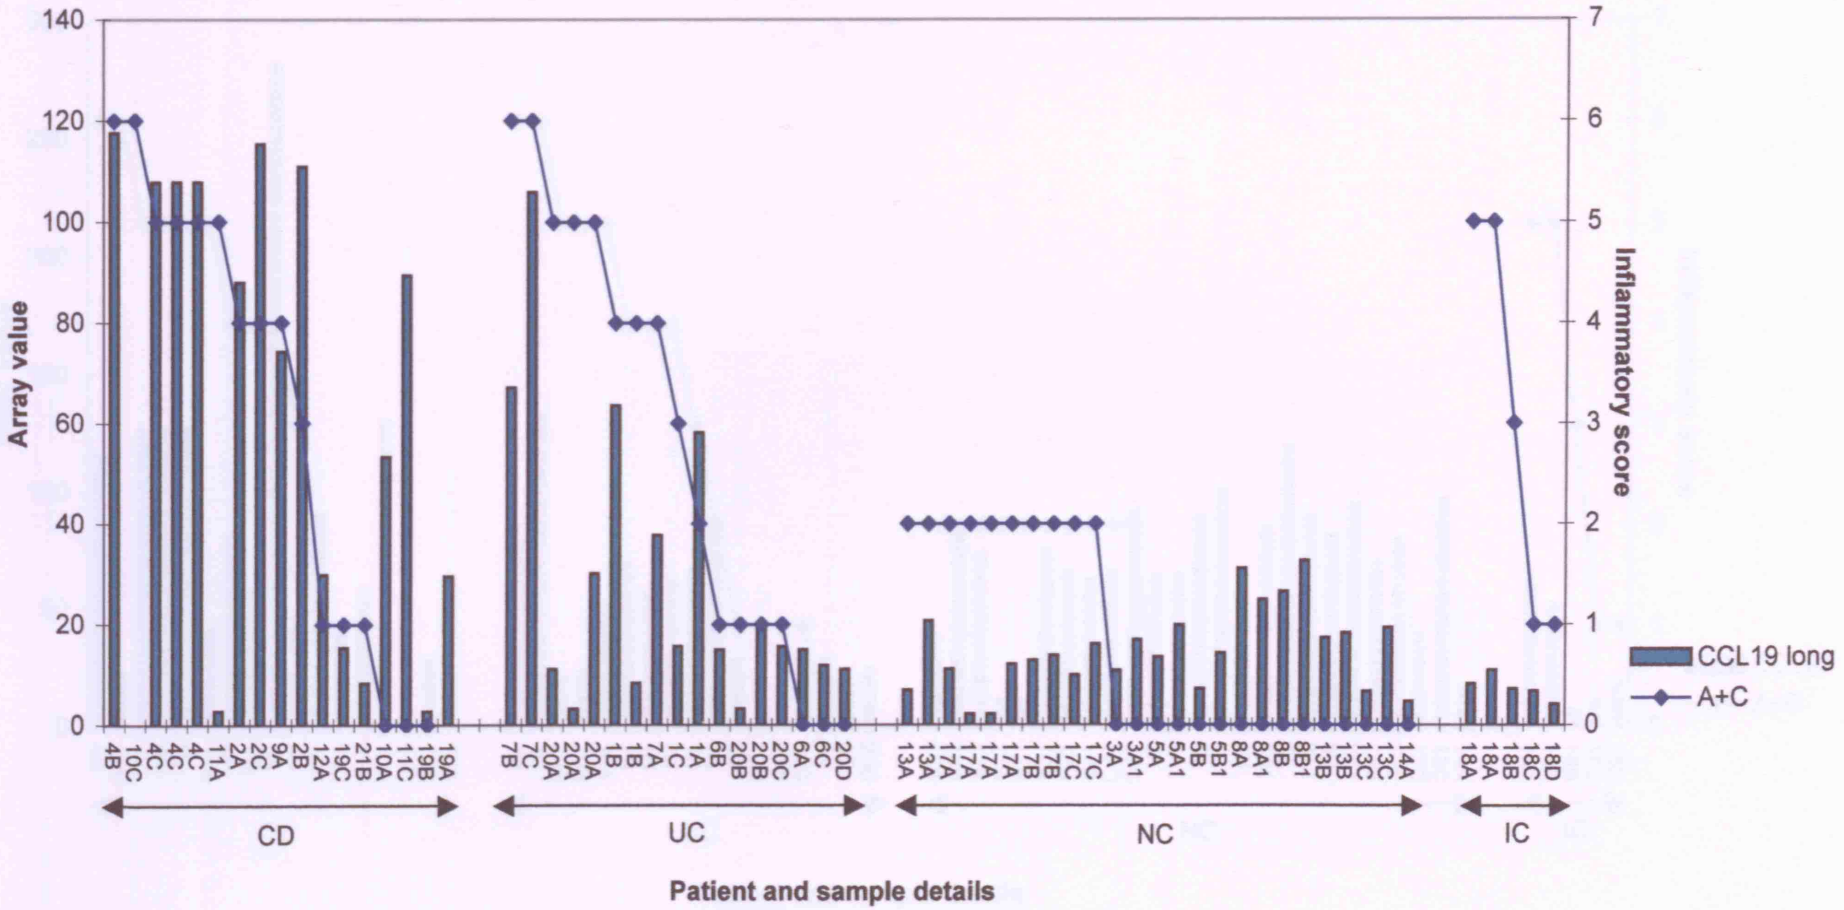
Patients are grouped according to disease, and chronologically placed according to infammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammatory control.

Graph 3.22: Relative expression levels of CCL19 (short arm) in full-thickness colonic tissue measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



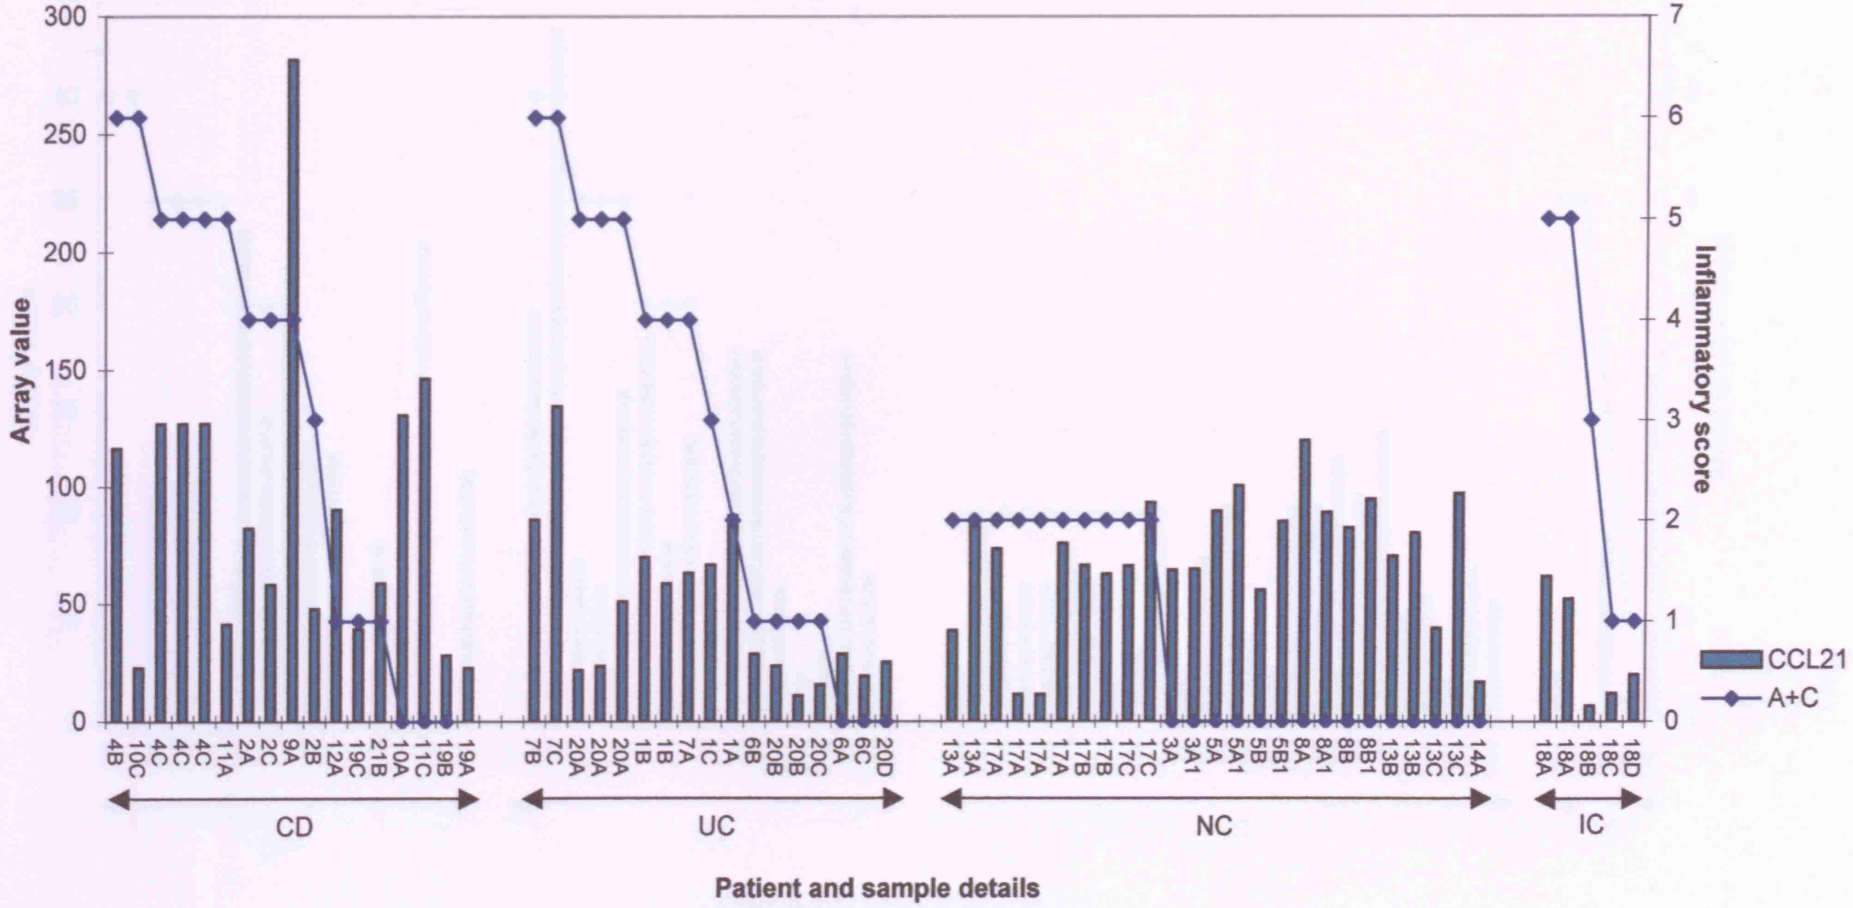
Patients are grouped according to disease and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix 2. NC=normal control IC=inflammatory control.

Graph 3.23: Relative expression levels of CCL19 (long arm) in full-thickness colonic tissue measured using microarray correlated with relative levels of inlammation as determined by histopathological analysis



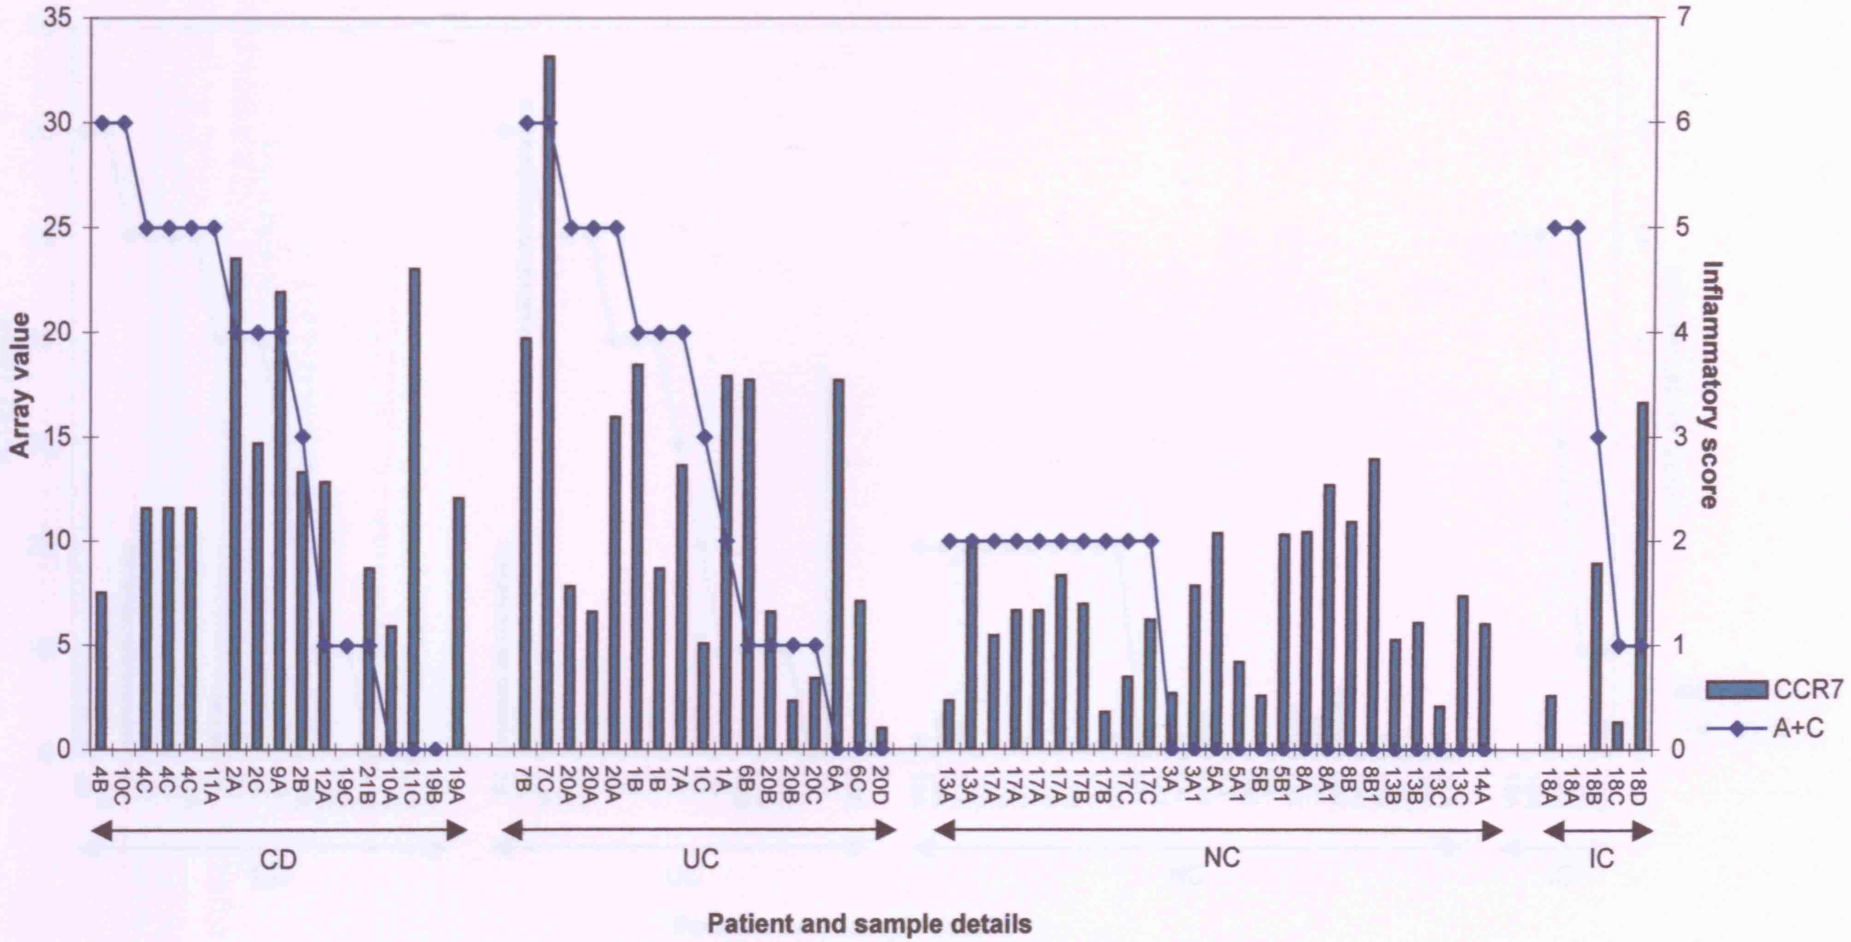
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammatory control.

Graph 3.24: Relative expression levels of CCL21 in full-thickness colonic tissue measured using microarray corelated with relative levels of inflammation as determined by histopathological analysis



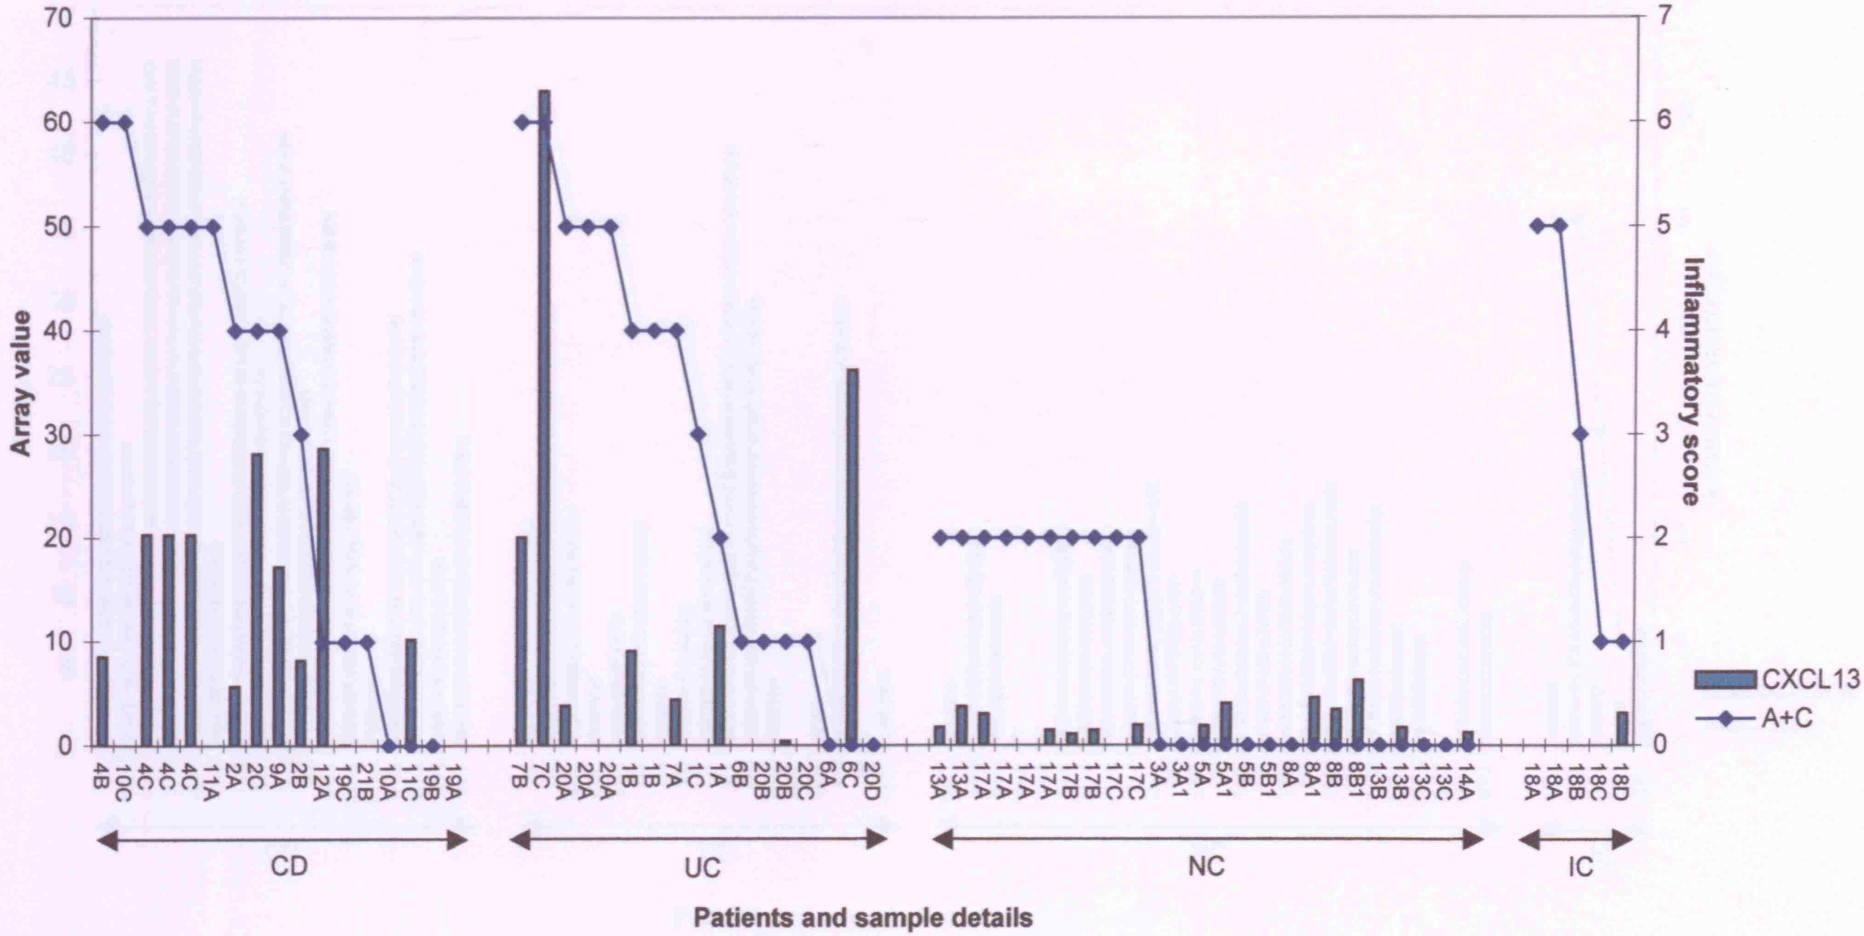
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix 2. NC=normal control, IC=inflammatory control.

Graph 3.25: Relative expression of CCR7 in full-thickness colonic tissue measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



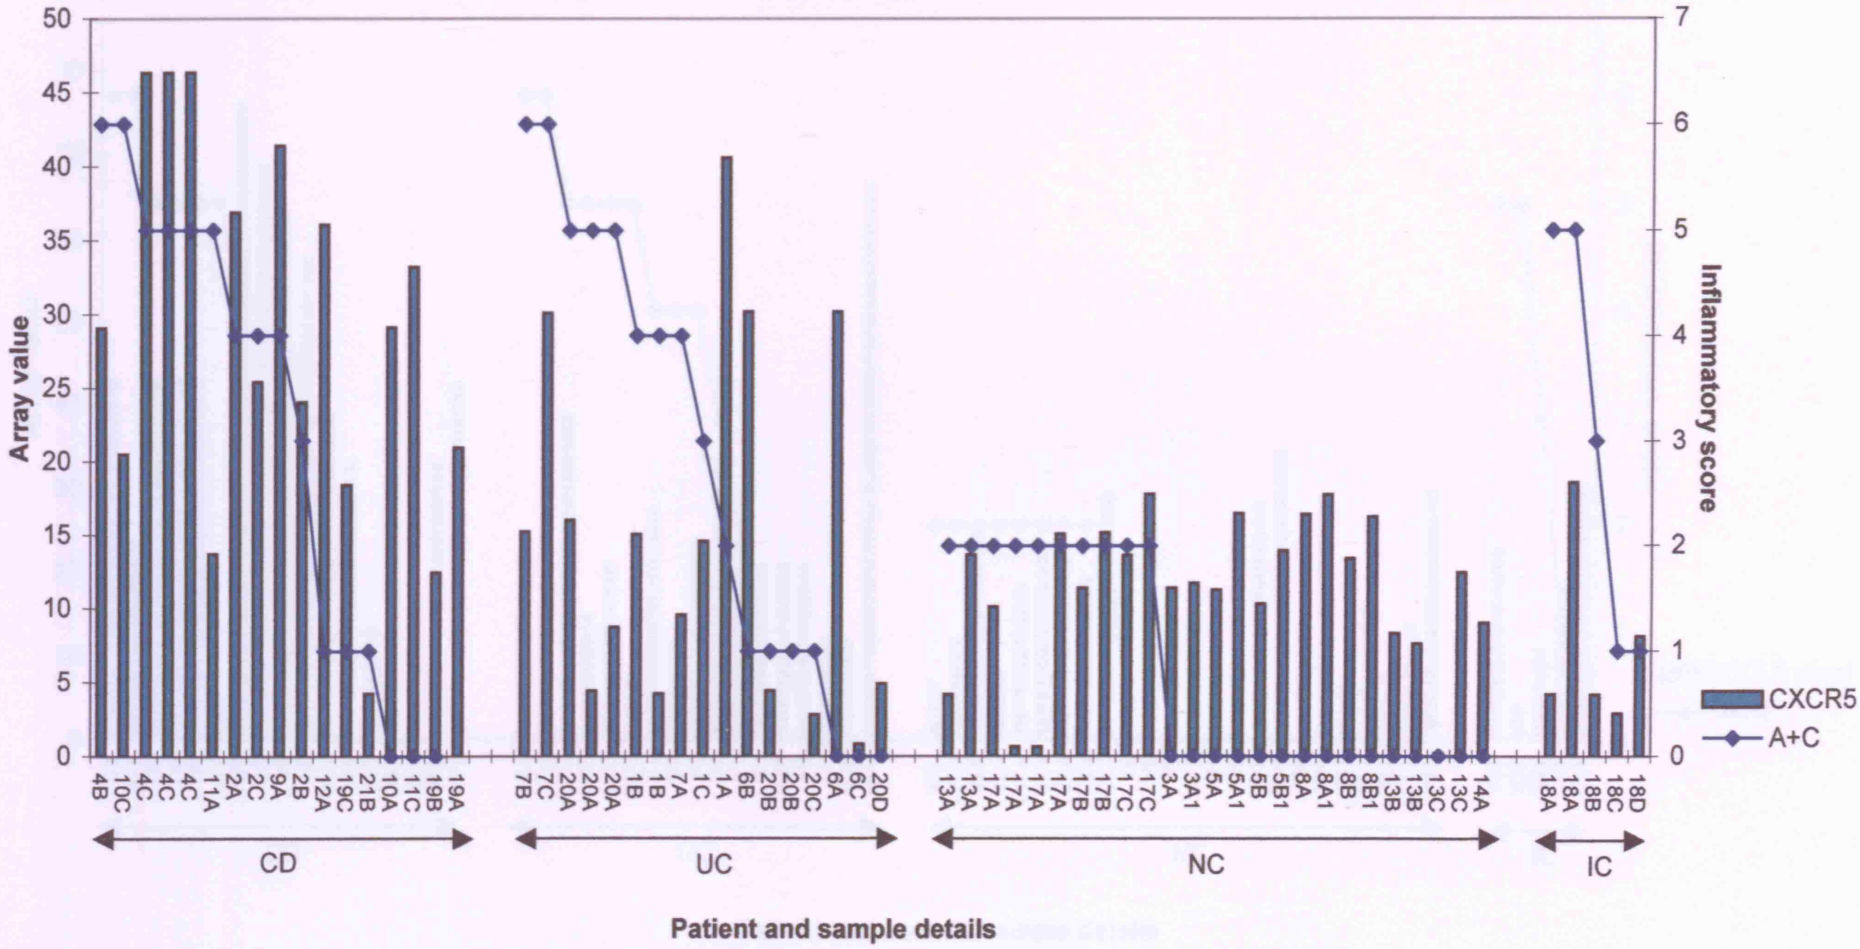
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix 2. NC=normal control, IC=inflammatory control.

Graph 3.26: Relative expression levels of CXCL13 in full-thickness colonic tissue measured using miocroarray correlated with relative levels of inflammation as determined by histopathological analysis



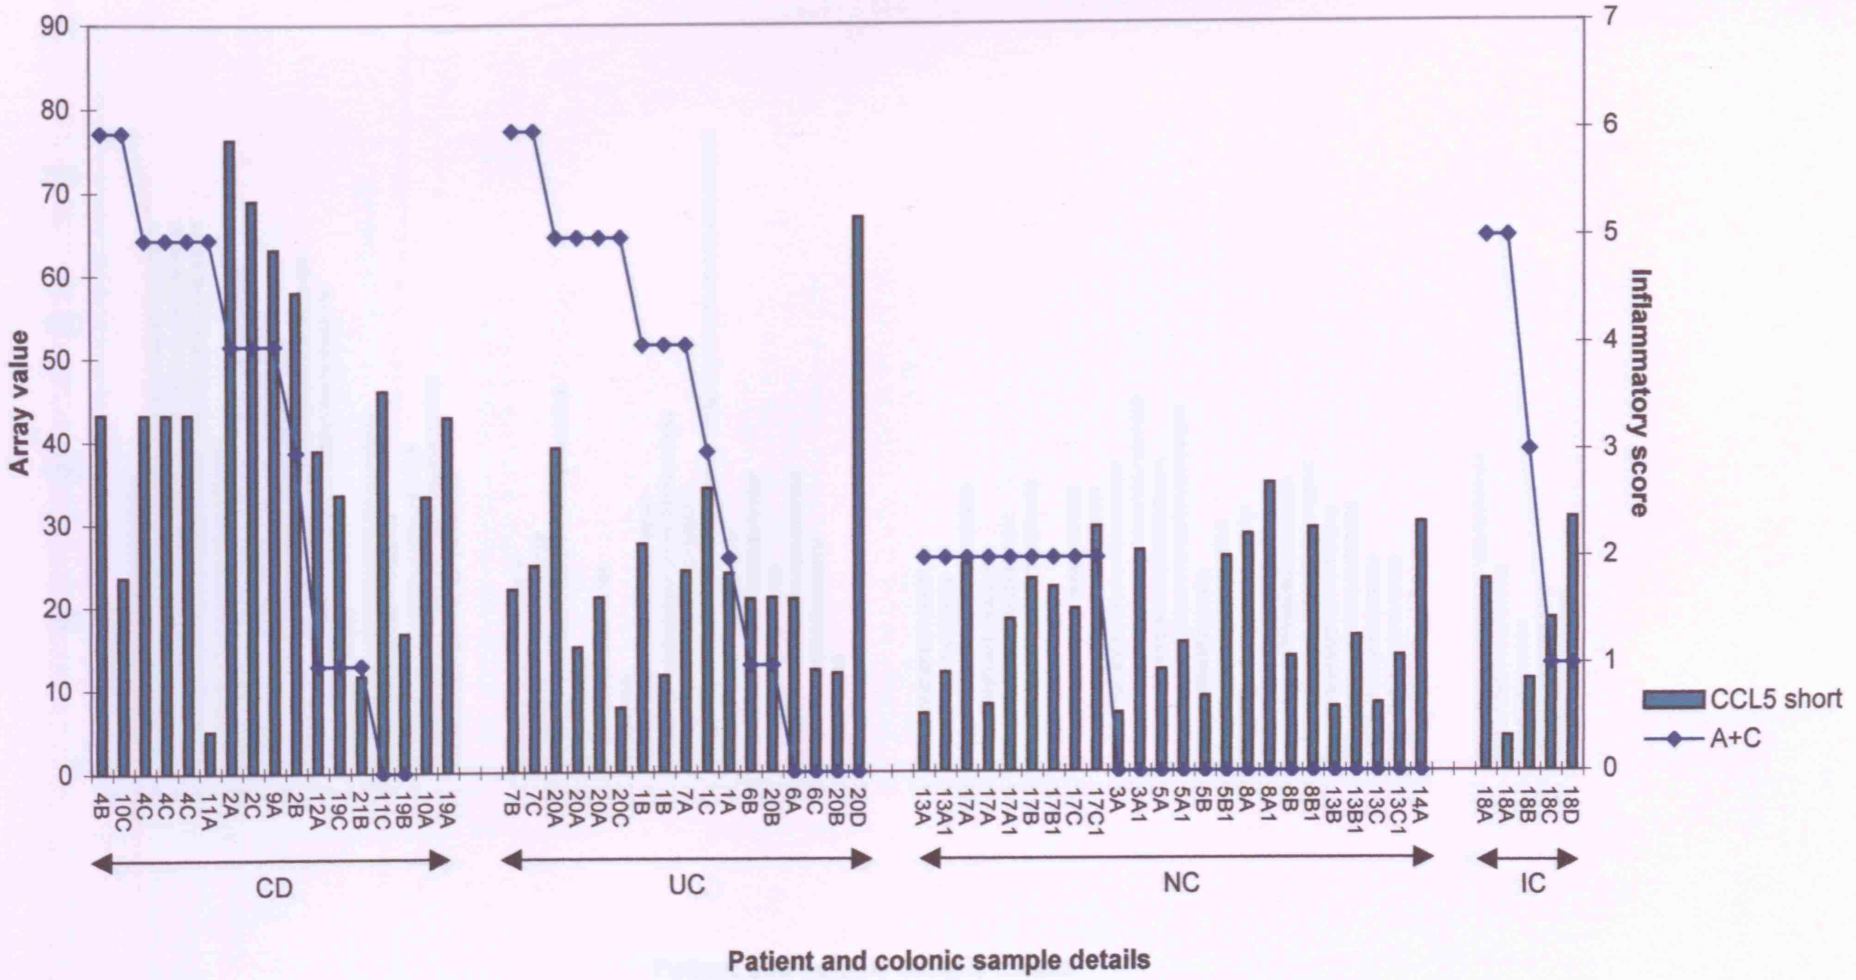
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix 2. NC=normal control, IC=inflammatory control.

Grpah 3.27: Relative expression levels of CXCR5 in full-thickness colonic tissue measured using microararray correlated with relative levels of inflammation as determined by histopathological analysis



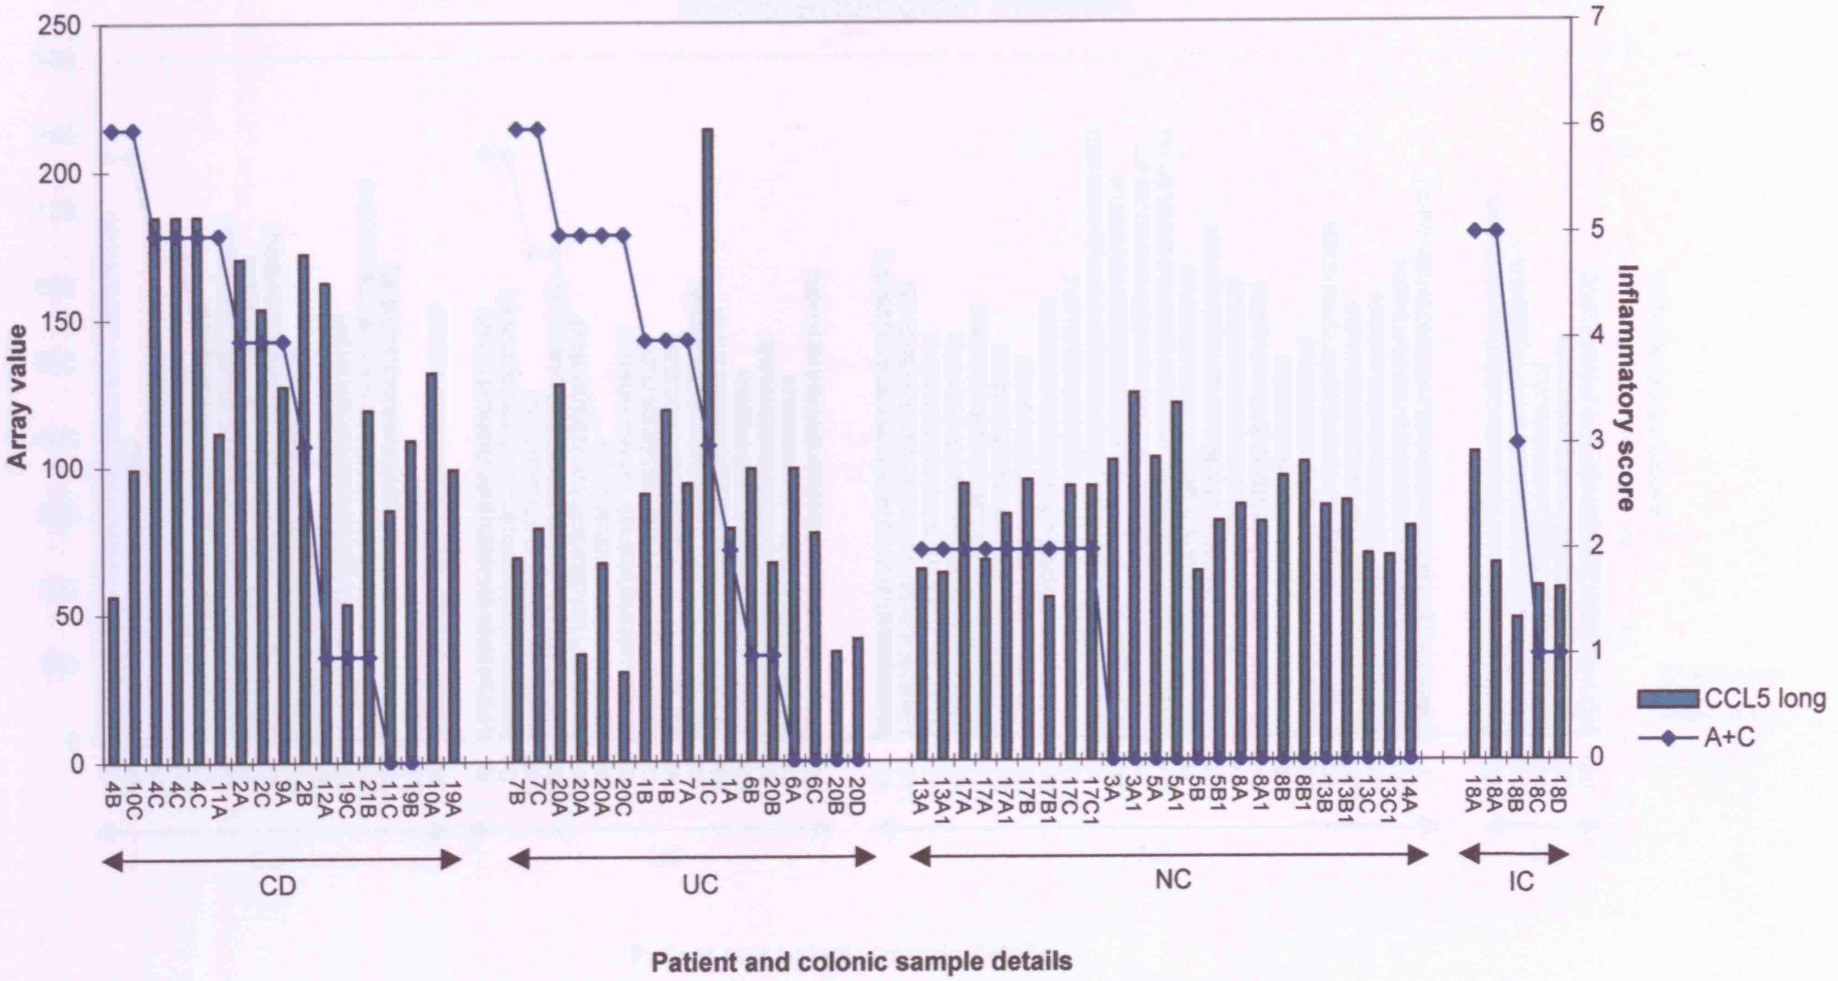
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix 2. NC=normal control, IC=inflammtory control.

Grpah 3.28: Relative expression of CCL5 short arm in full thickness colonic tissue measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



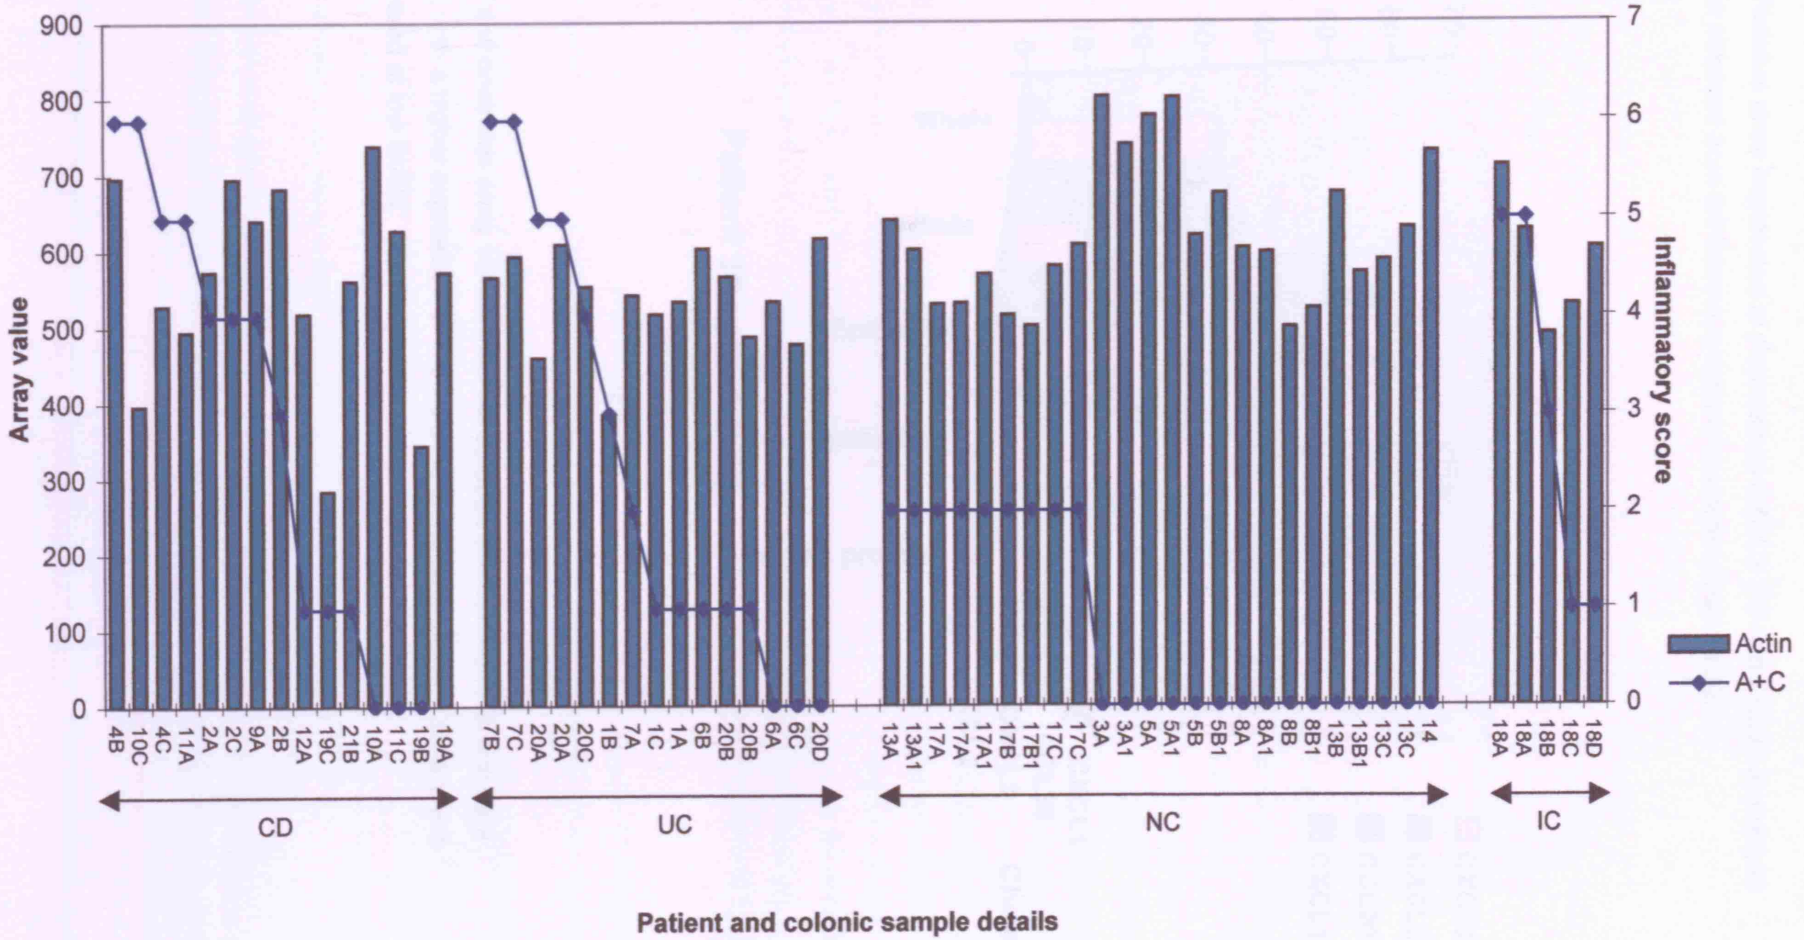
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammatory control.

Graph 3.29: Relative expression of CCL5L in full thickness colonic tissue measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



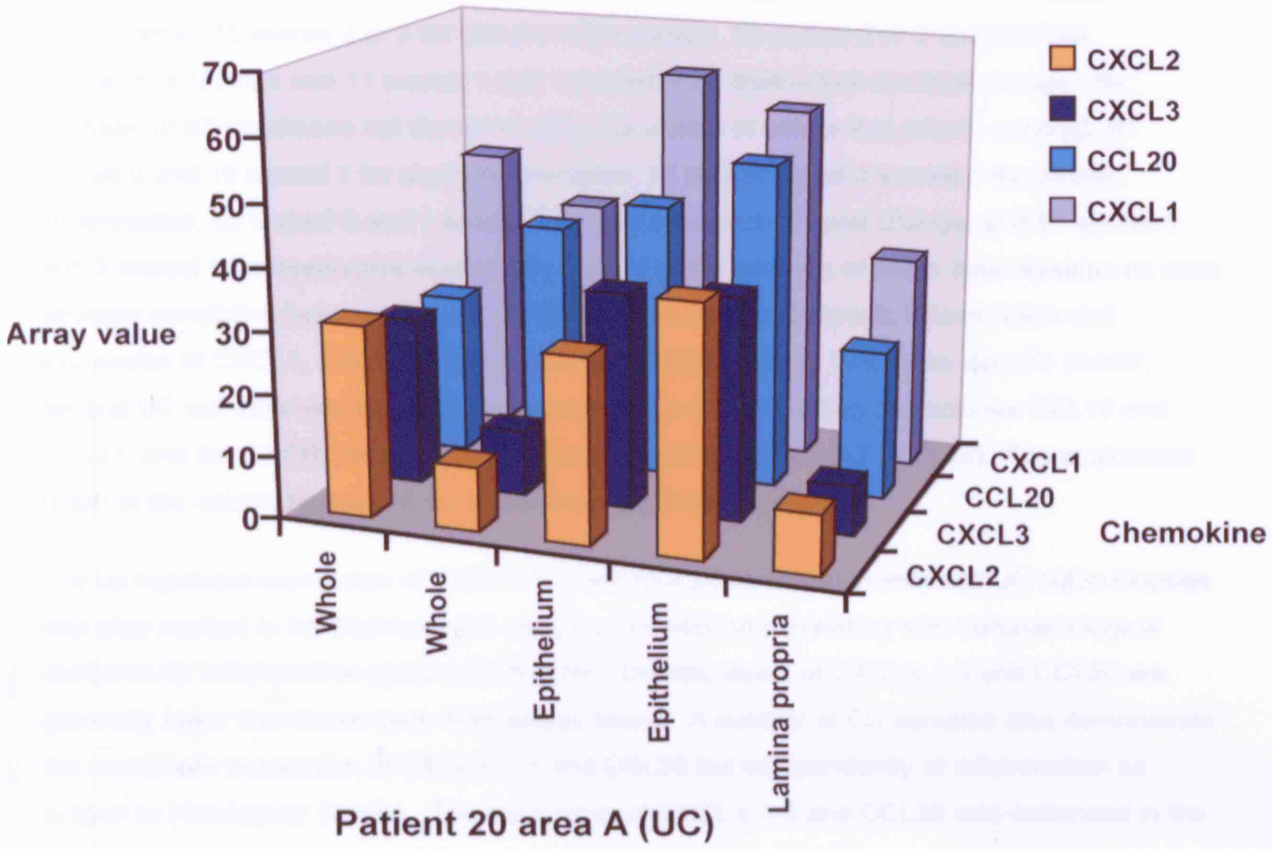
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control IC=inflammatory control.

Graph 3.30: Relative expression of actin in full thickness colonic tissue measured using microarray correlated with relative levels of inflammation as determined by histopathological analysis



Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammatory control.

Graph 3.31: Relative array expression of chemokines CXCL's 1-3 and CCL20 in stripped compartments obtained from full thickness colonic tissue from patient 20.



Graph 3.27 demonstrates array values from the stripped compartments in a severe case of UC, with a higher expression of chemokines in the epithelium. CCR6 levels were expressed at low levels.

3.2.3 Discussion

Of note, a cluster of 21 biopsies, taken from 5 UC and 1 CD patients, exhibited an expression profile clearly distinct from the other 101 profiles analysed. Within this exceptional cluster, much higher levels of gene expression were observed for a group of four chemokines, CXCL1, CXCL2, CXCL3, and CCL20, in comparison to other samples (graphs 3.3-3.6). The high histopathological quotients for inflammation, destructive mucosal change, and glandular architecture change assigned to these colon samples, further distinguishes this cluster. Of 20 specimens demonstrating this cluster (1 lost prior to scoring), 16 scored 2 or 3 for acute inflammation, 15 scored 2 or 3 for chronic inflammation, 16 scored 2 or 3 for glandular architecture change and 11 scored 1 and 1 scored 3 for destructive mucosal change. By contrast, of 97 specimens not demonstrating this cluster (4 others lost prior to scoring), 67 scored 0 and 19 scored 1 for acute inflammation, 91 scored 0 and 5 scored 1 for chronic inflammation, 95 scored 0 and 1 scored 1 for glandular architectural change, and 94 scored 0 and 3 scored 1 for destructive mucosal change. Further analysis of these data revealed an even stronger correlation between a cumulative score for acute and chronic inflammation and expression of CXCL1, CXCL2, CXCL3 and CCL20 (Graph 3.2). Within the specific cluster, several UC samples also exhibited expression of the CCR7 binding chemokines CCL19 and CCL21, and the CXCR5 binding chemokine, CXCL13 (graphs 3.9-3.11, 3.13). The anatomical origin of the colonic biopsy did not affect the chemokine expression.

The up regulated expression of CXCL's 1-3 and CCL20 observed in inflamed UC colon biopsies was also marked in full-thickness UC samples, expression correlating with histopathological quotients for inflammation (graphs 3.16-3.19). Overall, levels of CXCL's 1-3 and CCL20 are generally lower than those seen from biopsy tissue. A number of CD samples also demonstrate the coordinate expression of CXCL's 1-3 and CCL20 but independently of inflammation as judged by histological scoring. The expression of CXCL's 1-3 and CCL20 was enhanced in the full thickness specimens from CD patients in comparison to biopsies.

Interestingly, four specimens from a patient diagnosed with diverticulitis exhibited coordinated expression of CXCL's 1-3 and CCL20, expression levels correlating with inflammatory quotient.

Increased expression of CCL5 (RANTES) was observed in full thickness samples that was not detected at similar levels in any biopsy samples analysed in this study (graphs 3.27-3.28). CCL5 and CCR5 were expressed at generally higher levels in the CD cohort than the UC and control cohorts, while no significant difference was found between UC and control. Levels of chemokine expression did not correlate with inflammatory quotient.

Stripped epithelial analysis was limited to one patient who had severe UC. Expression of CXCL's 1-3 and CCL20 was higher in the epithelium than in the lamina propria (tables 3.5 and graph 3.30).

Formal statistical analysis of array data is not appropriate as they merely represent semi-quantisation. Such analysis is only appropriate for RT-PCR values.

Although ESR and CRP values were elevated in cases of inflamed compared to non-inflamed biopsy tissue, there was no reliable correlation between chemokine induction and inflammatory blood values. There was an overall tendency for CRP to be particularly elevated in CD and inflammatory colitis, and the ESR was higher in patients with UC. Results are included in appendix 2.3, 3.4 and 4.4. In full thickness tissue samples, there was some correlation between CRP and A+C, and therefore correlated with chemokine induction in a similar fashion.

3.3 Real time quantitative PCR (RT-PCR)

3.3.1 Background

In order to confirm and further quantify the microarray findings, real time quantitative reverse transcriptase coupled PCR (RT-PCR) was performed for CXCL's 1-3, 8-11, CCL's 3, 5, 20, 24, CCR's 5-6, CXCR's 1-3 on a subset of samples used for microarray analysis. The relative level of up regulated expression of these chemokines in inflamed IBD colon is expressed as a percentage of the average transcript copy number detected for the non-IBD cohort, normalised to 18S rRNA copy number. This data was compared to the histopathological quotient for inflammation.

3.3.2 RT-PCR technique

Quantitative reverse transcriptase polymerase chain reaction was performed as described in 2.2.2.6. The normalised data was compared to the histopathological quotients for inflammation.

3.3.3 Results

The data are listed in tables 3.9-11 and demonstrated in graphs 3.32-3.53.

Multiple non-paired t-test analyses of PCR results within colonic biopsy samples from CD/UC/normal control groups were performed on CXCR1, CXCR2, CXCL1, CXCL3, CXCL8, CCL20 and CCR6. There is a significant up regulation of the following in UC compared to normal control:

UC			
Chemokine	**Mean**	**Confidence interval**	**P value**
CXCL1	224.85	113.41 - 336.30	0.0003
CXCL3	122.72	63.77 - 181.68	0.0002
CXCL8	785.88	275.93 - 1295.83	0.004
CCL20	52.60	16.89 - 88.30	0.007
CXCR1	48.66	30.62 - 66.70	0.00001
CXCR2	41.17	24.75 - 57.59	0.00003
CCR6	19.66	11.03 - 28.29	0.0002

There is statistical up regulation of the same chemokines in CD compared to normal control only when CD samples were excluded where the corresponding biopsy assessed for histopathological inflammation had a quotient of A+C = 0.

CD			
Chemokine	**Mean**	**Confidence interval**	**P value**
CXCL1	21.96	3.36 - 40.56	0.009
CXCL3	12.09	3.01 - 21.17	0.004
CXCL8	222.19	0 - 457.45	0.017
CCL20	10.23	0.19 - 20.27	0.03
CXCR1	13.04	2.61 - 23.44	0.008
CXCR2	8.72	1.18 - 16.26	0.018

When a similar exclusion was applied to the UC subset, the statistical significance of up regulation increased, as listed below:

UC			
Chemokine	**Mean**	**Confidence interval**	**P value**
CXCL1	323.04	190.14 - 453.94	0.000001
CXCL3	176.25	106.83 - 245.67	0.000001
CXCL8	1138.66	458.72 - 1818.60	0.0003
CCL20	77.32	29.48 - 125.16	0.0005
CXCR1	66.63	47.53 - 85.53	0.000000004
CXCR2	58.06	40.74 - 75.38	0.000000009
CCR6	27.60	17.46 - 37.74	0.000001

Multiple non-paired t-test analyses were applied to the PCR values obtained from full-thickness colonic samples on chemokines CXCL1, CXCL9, CXCL10, CXCL11, CCL2, CCL3, CCL5, CCL20, CCL24, in addition to chemokine receptors CCR3, CCR5, CXCR1, CXCR2 and CXCR3. There is a significant up regulation of the following in IBD compared to normal control:

CD			
Chemokine	**Mean**	**Confidence interval**	**P value**
CCL5	12.33	8.06 - 16.60	0.0058
CCR5	39.25	25.62 - 52.88	0.009
CXCR3	2.98	1.90 - 4.06	0.023

Non-parametric analyses correlating inflammatory scores A+C with corresponding RT-PCR values for CCL20, CCR6, CXCR1 and CXCR2 indicated statistically significant-associations. Spearman's correlation coefficients were as follows: 0.66 ($p<0.005$) for CCL20, 0.48 ($p<0.005$) for CCR6, 0.68 ($p<0.005$) for CXCR1 and 0.66 ($p<0.005$).

Table 3.9: Relative expression levels of CXCR1, CXCR2, CXCL1, CXCL3, CXCL8, CCL20 and CCR6 in colonic biopsy tissue obtained by quantitative PCR, normalised as outlined in 2.2.2.6. NC=normal control.

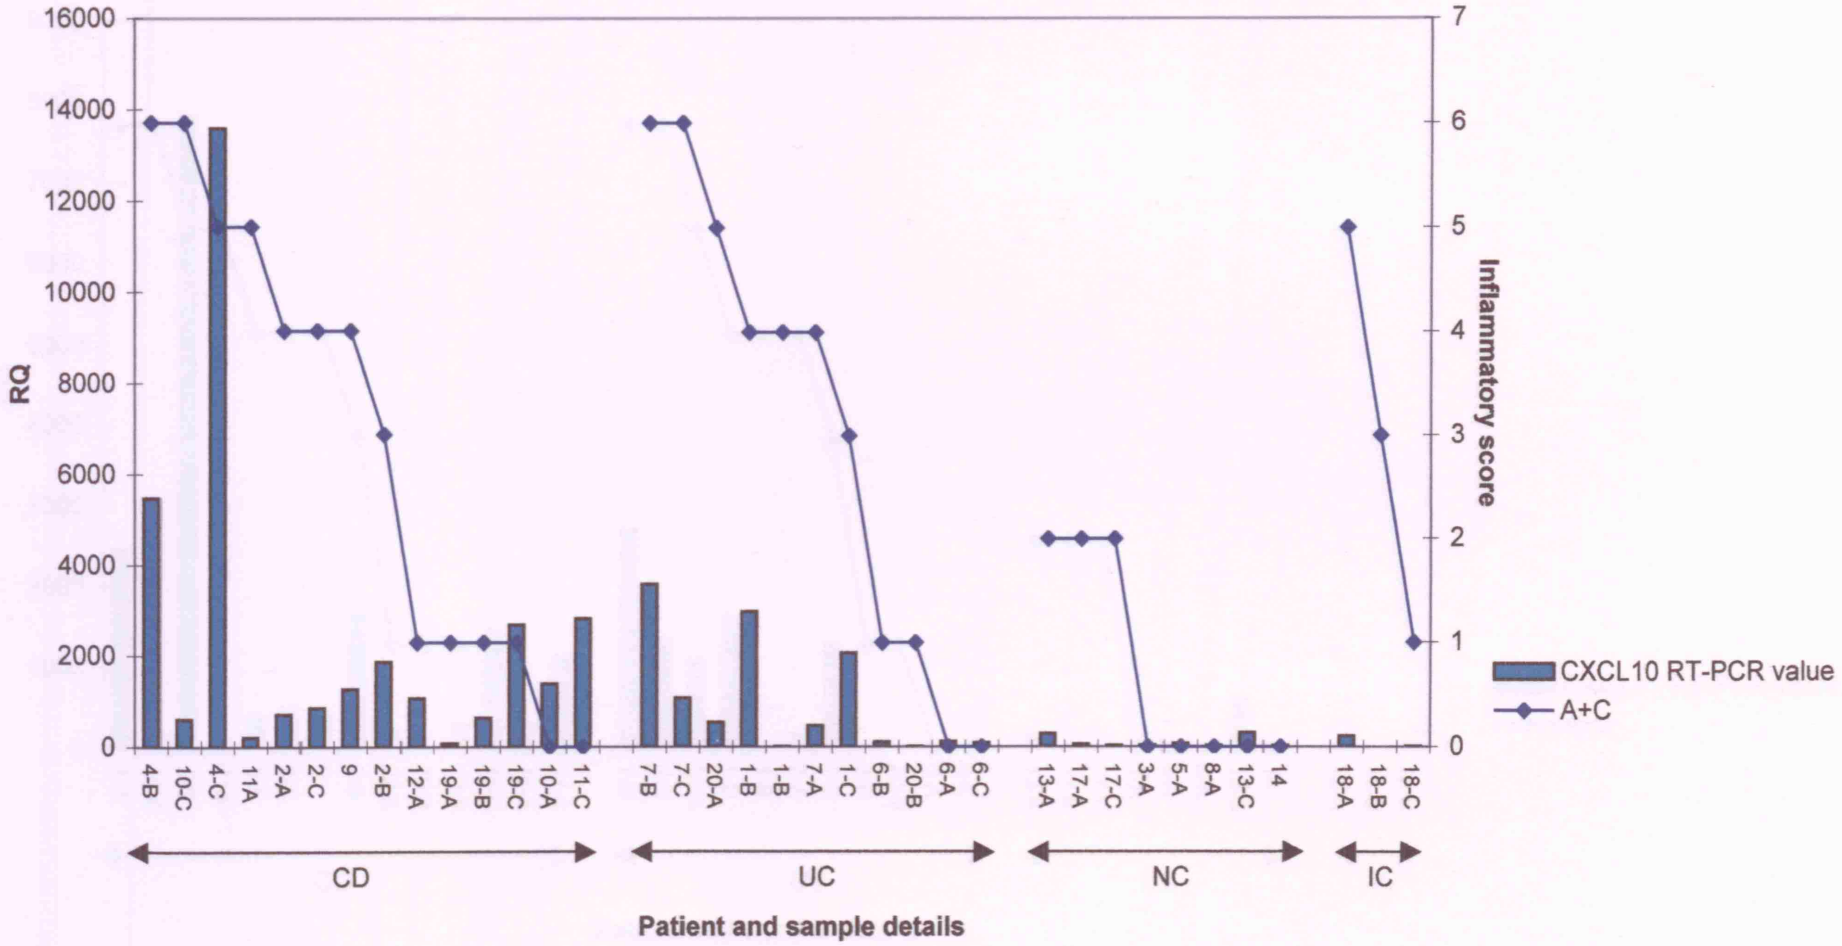
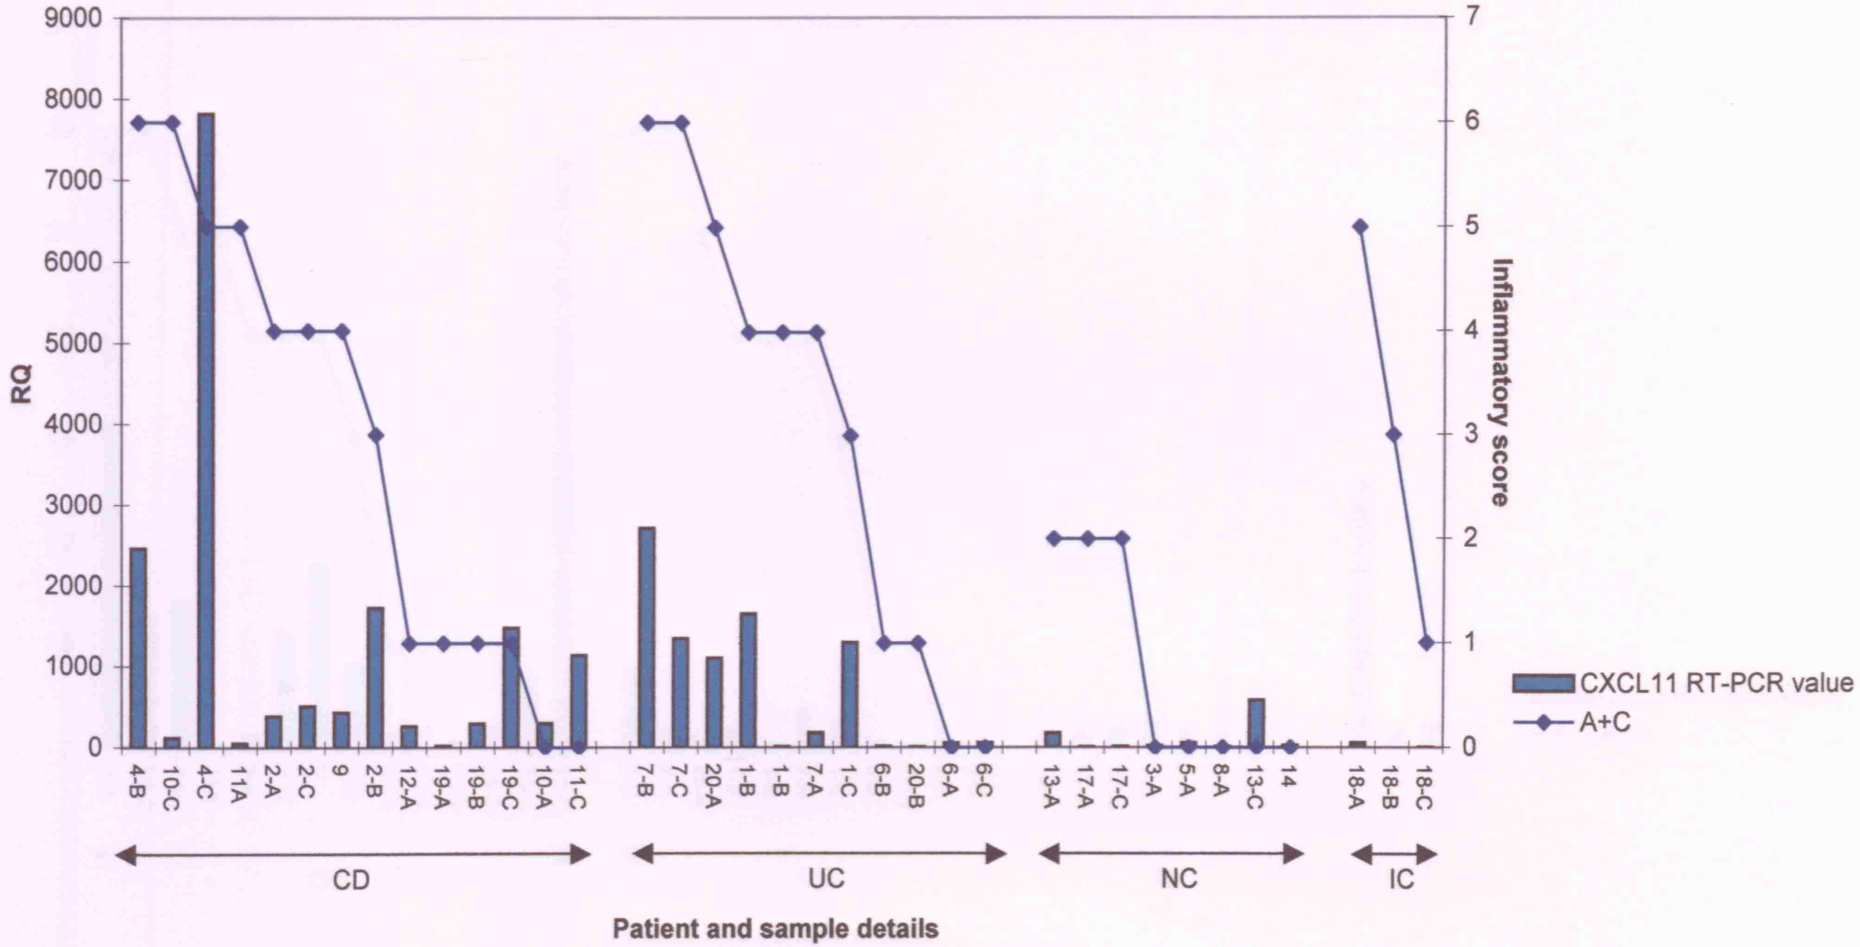
Graph 3.44: Relative expression of CXCL10 in full thickness colonic tissue measured by RT-PCR corrrelated with relative levels of inflammation as determined by histopathological analysis



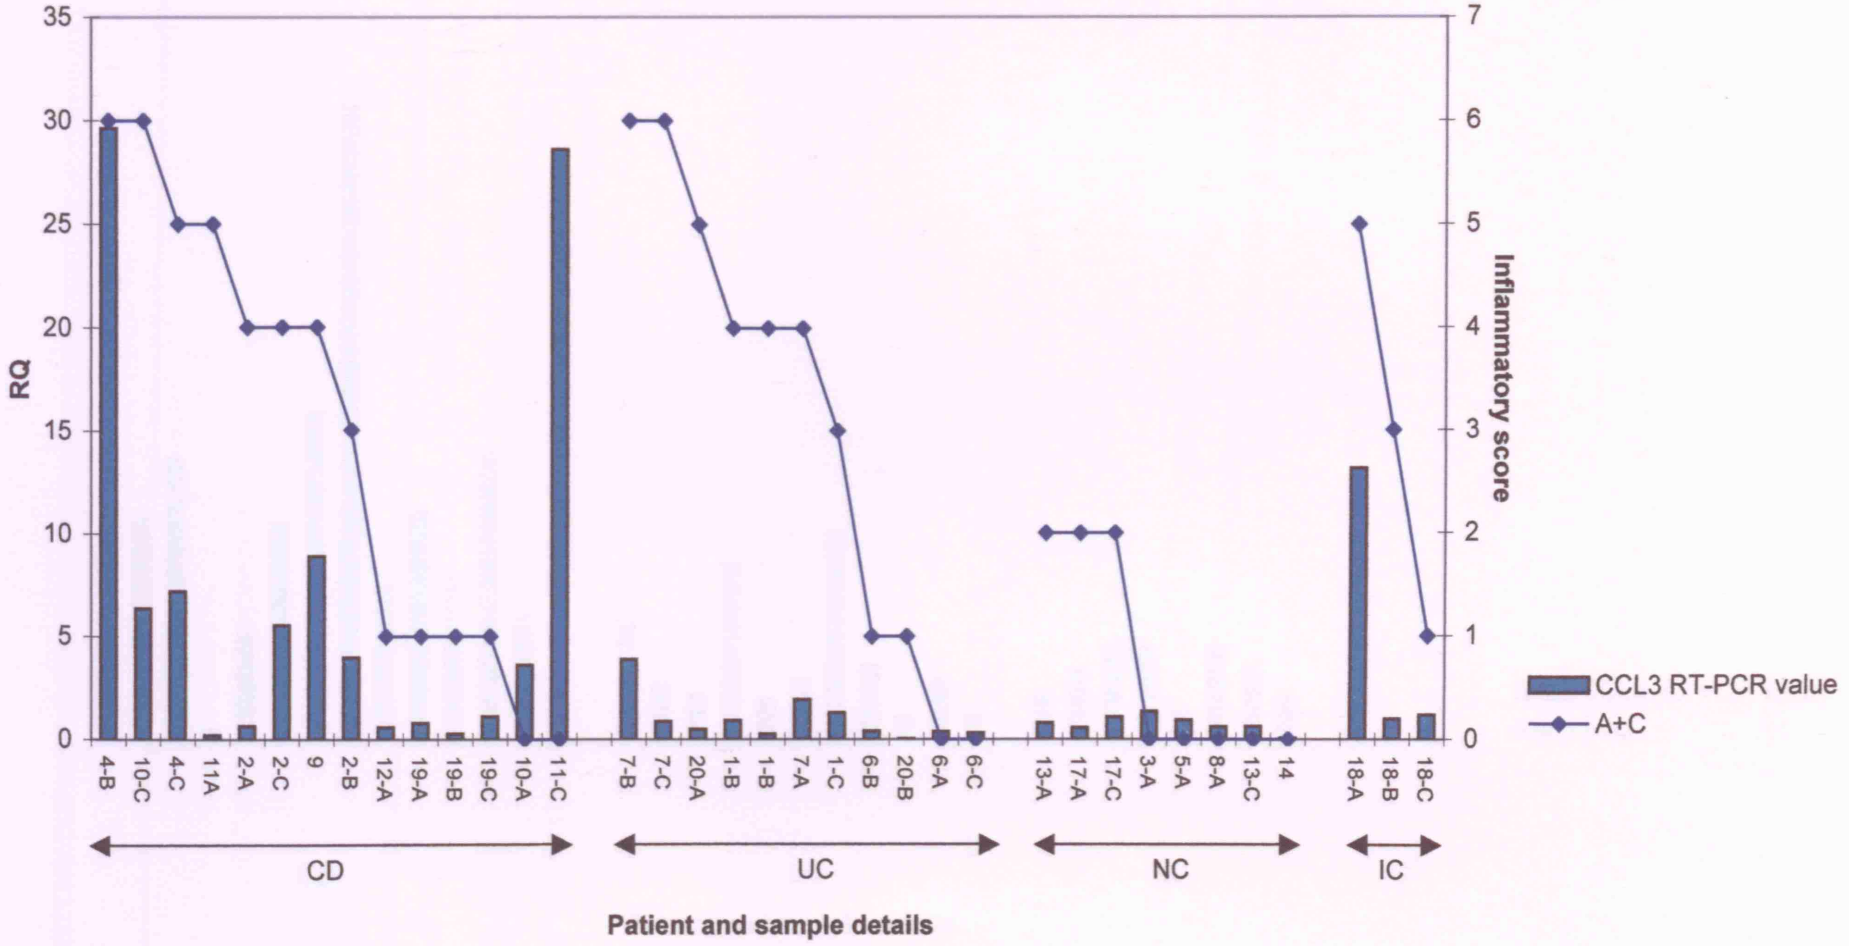
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outined in appendix table 2.3. NC=normal control, IC=inflammtory control.

Graph 3.45: Relative expression of CXCL11 in full thickness colonic tissue measured by RT-PCR corrrelated with relative levels of inflammation as determined by histopathological analysis



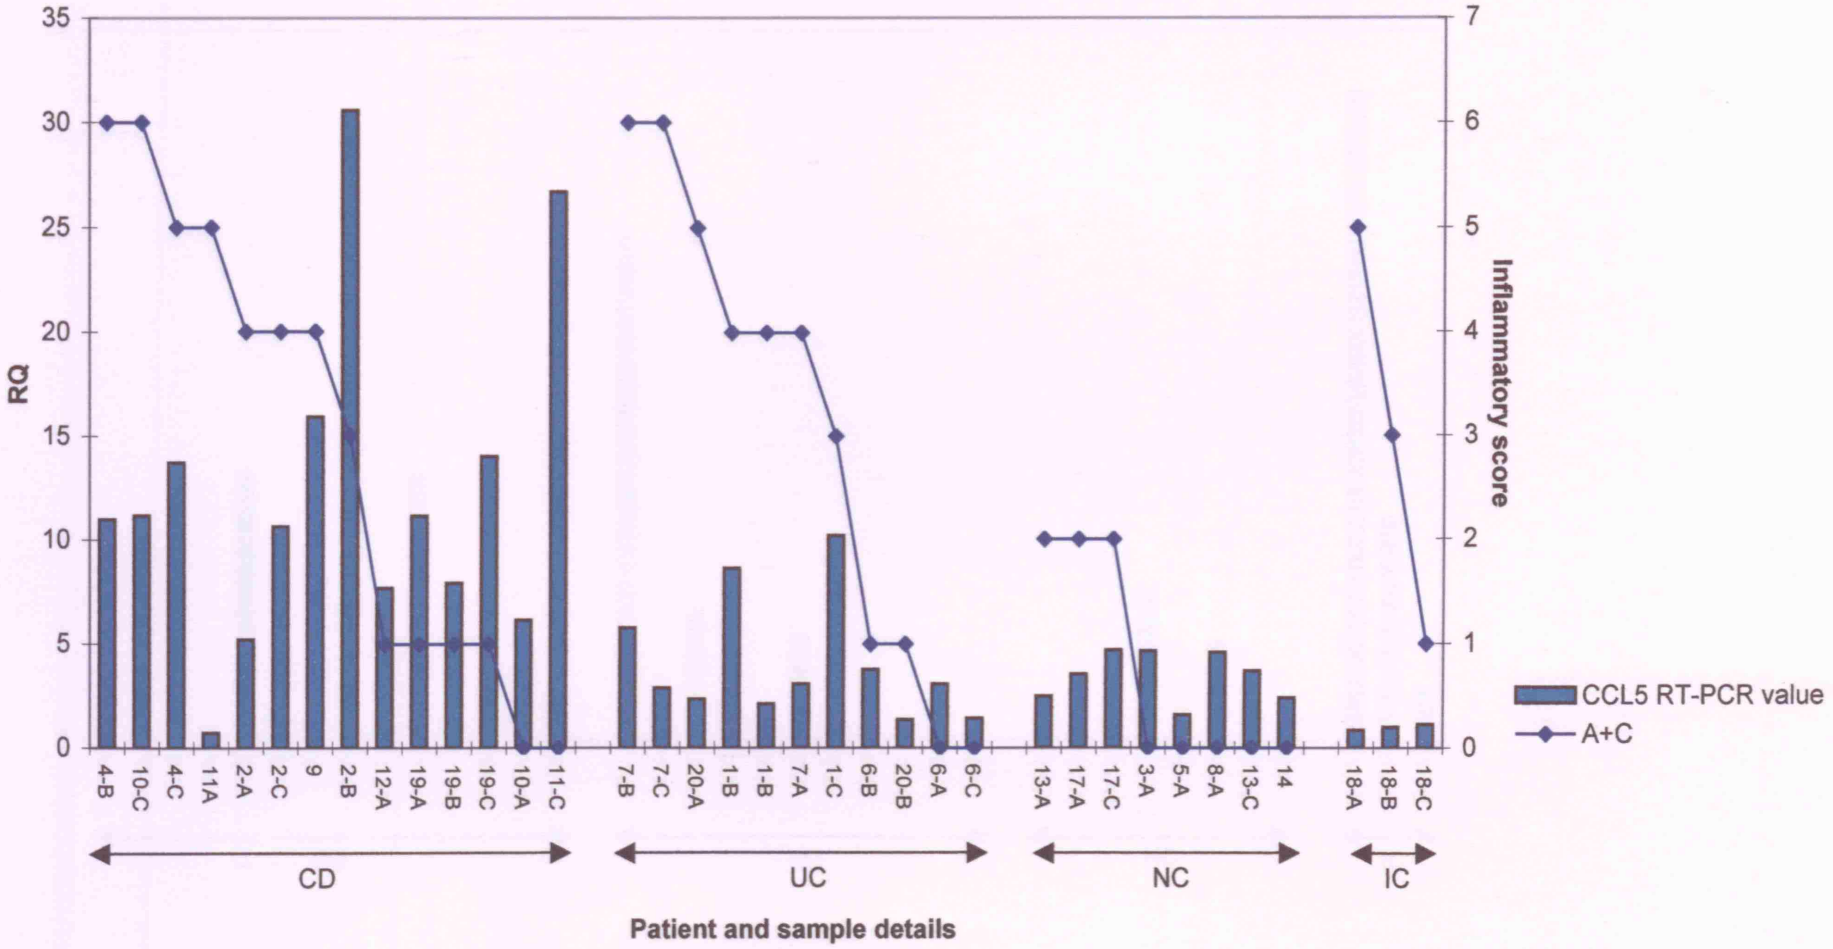
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A=C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammtory control.

Graph 3.46: Relative expression of CCL3 in full thickness colonic tissue measured by RT-PCR corrrelated with relative levels of inflammation as determined by histopathological analysis



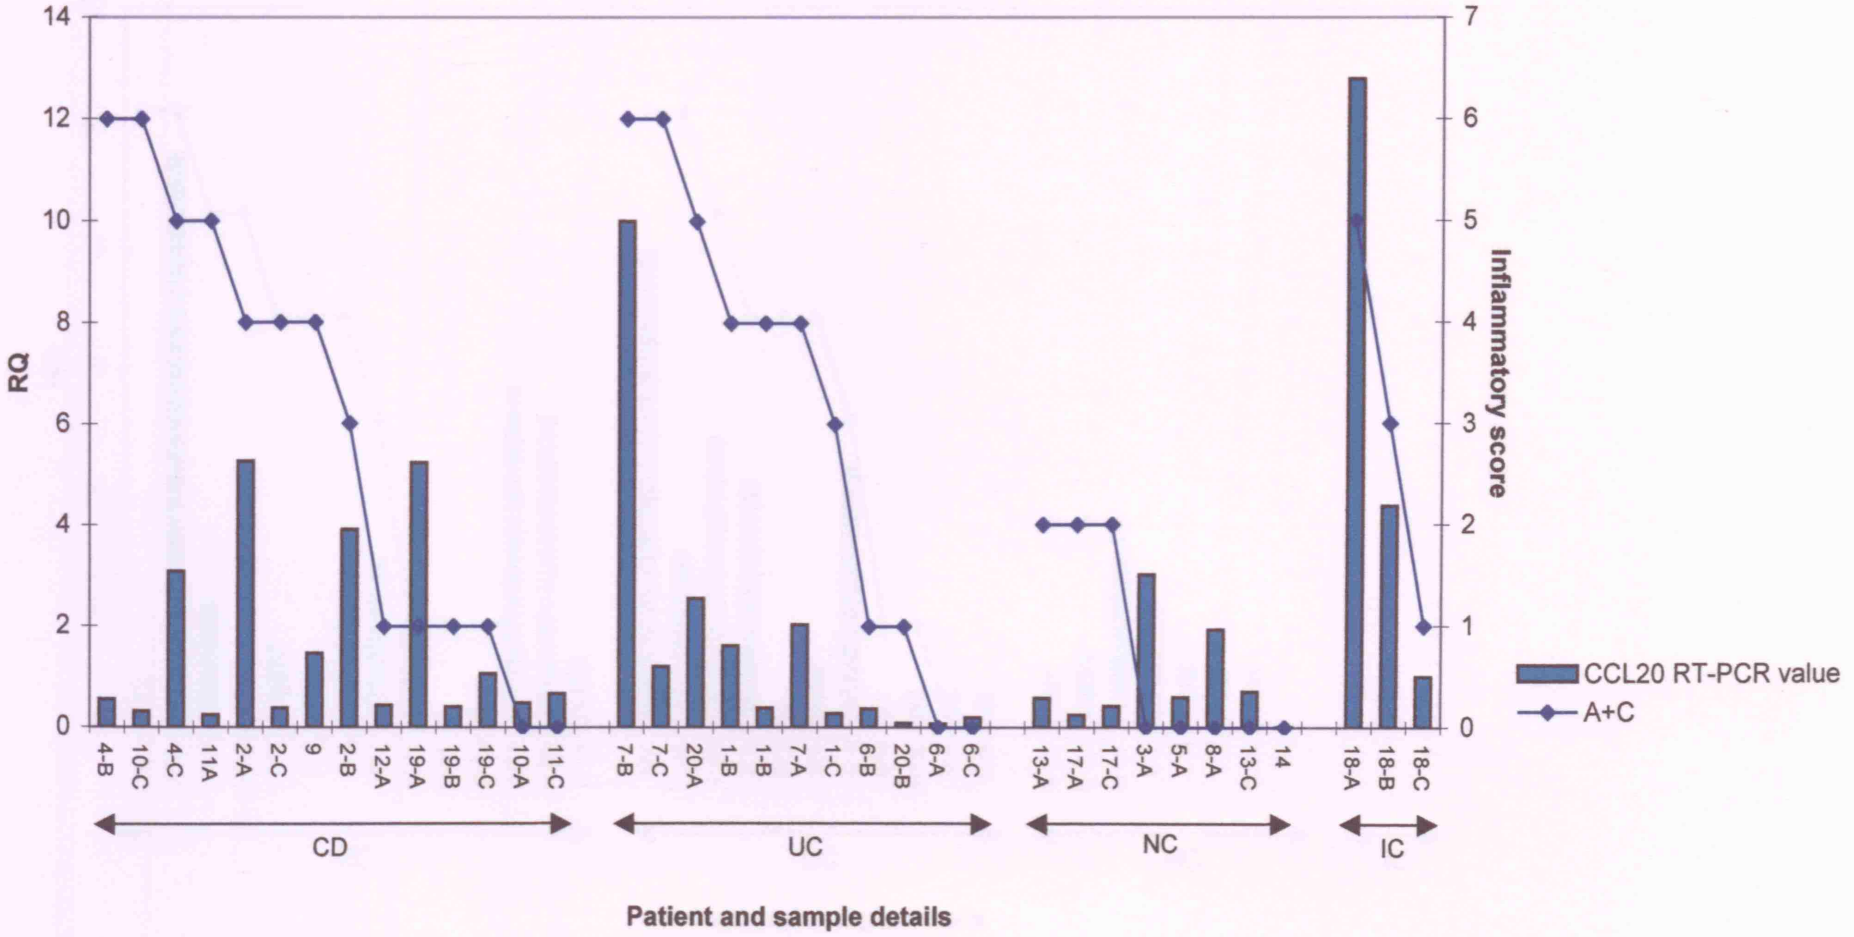
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammtory control.

Graph 3.47: Relative expression of CCL5 in full thickness colonic tissue measured by RT-PCR corrrelated with relative levels of inflammation as determined by histopathological analysis



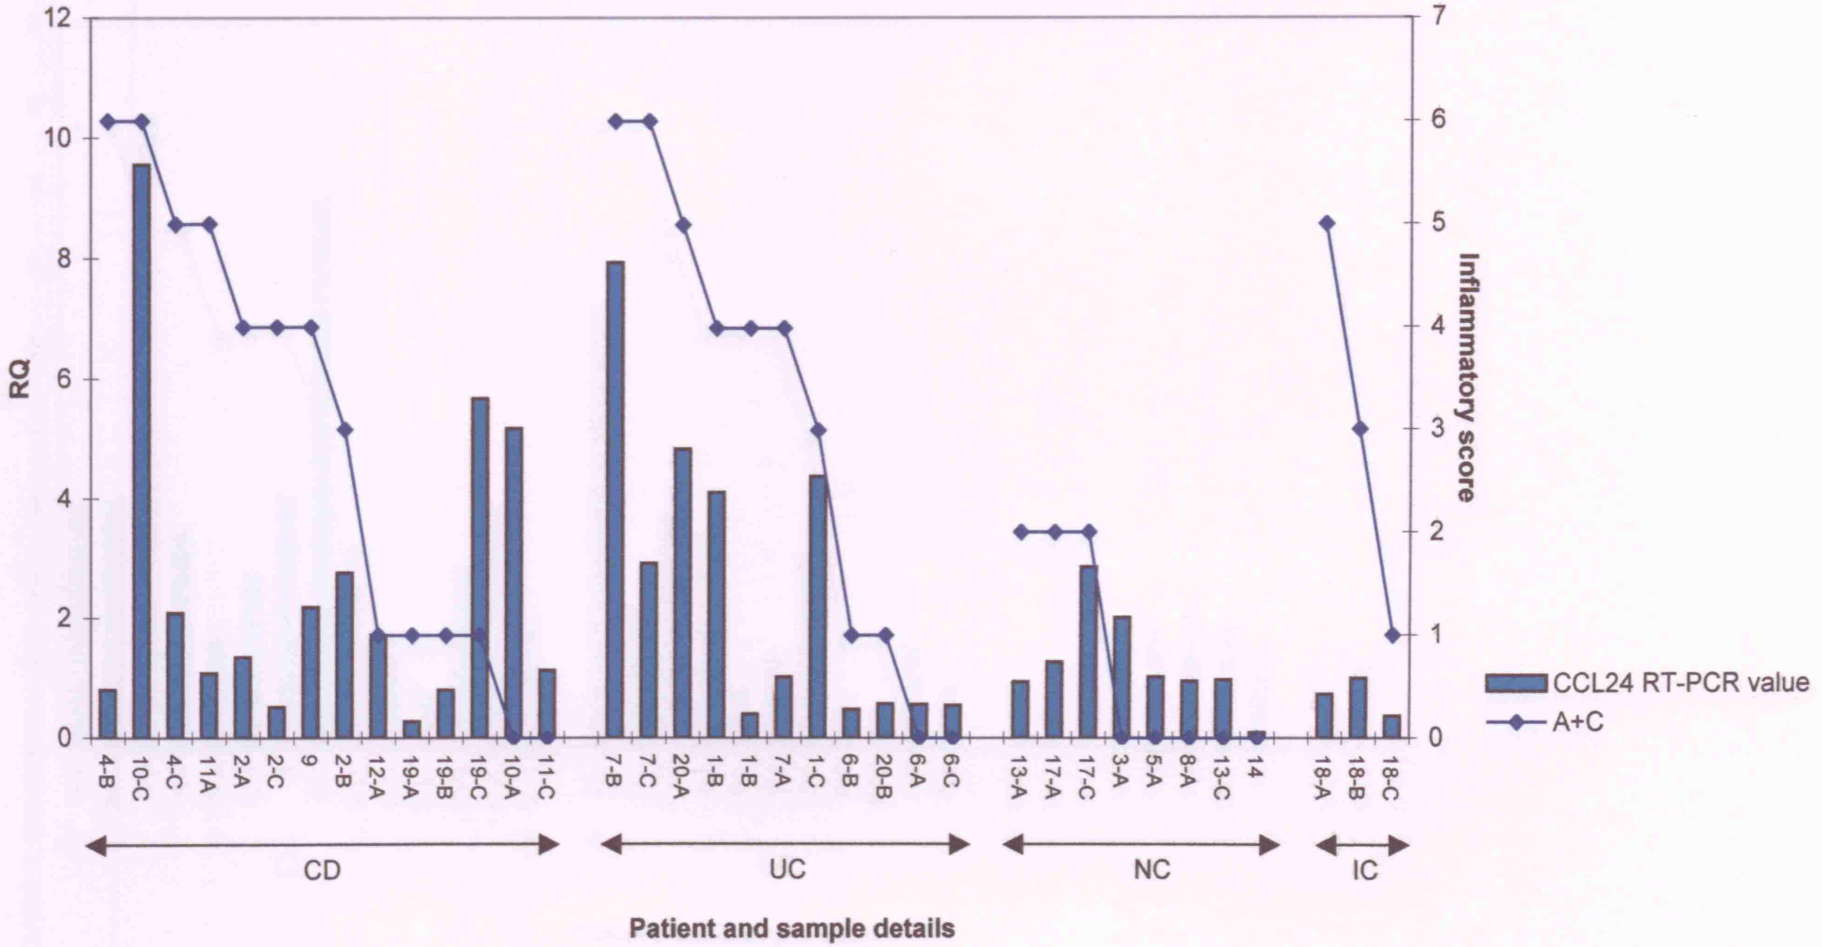
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammatory control.

Graph 3.48: Relative expression of CCL20 in full thickness colonic tissue measured by RT-PCR corrrelated with relative levels of inflammation as determined by histopathological analysis



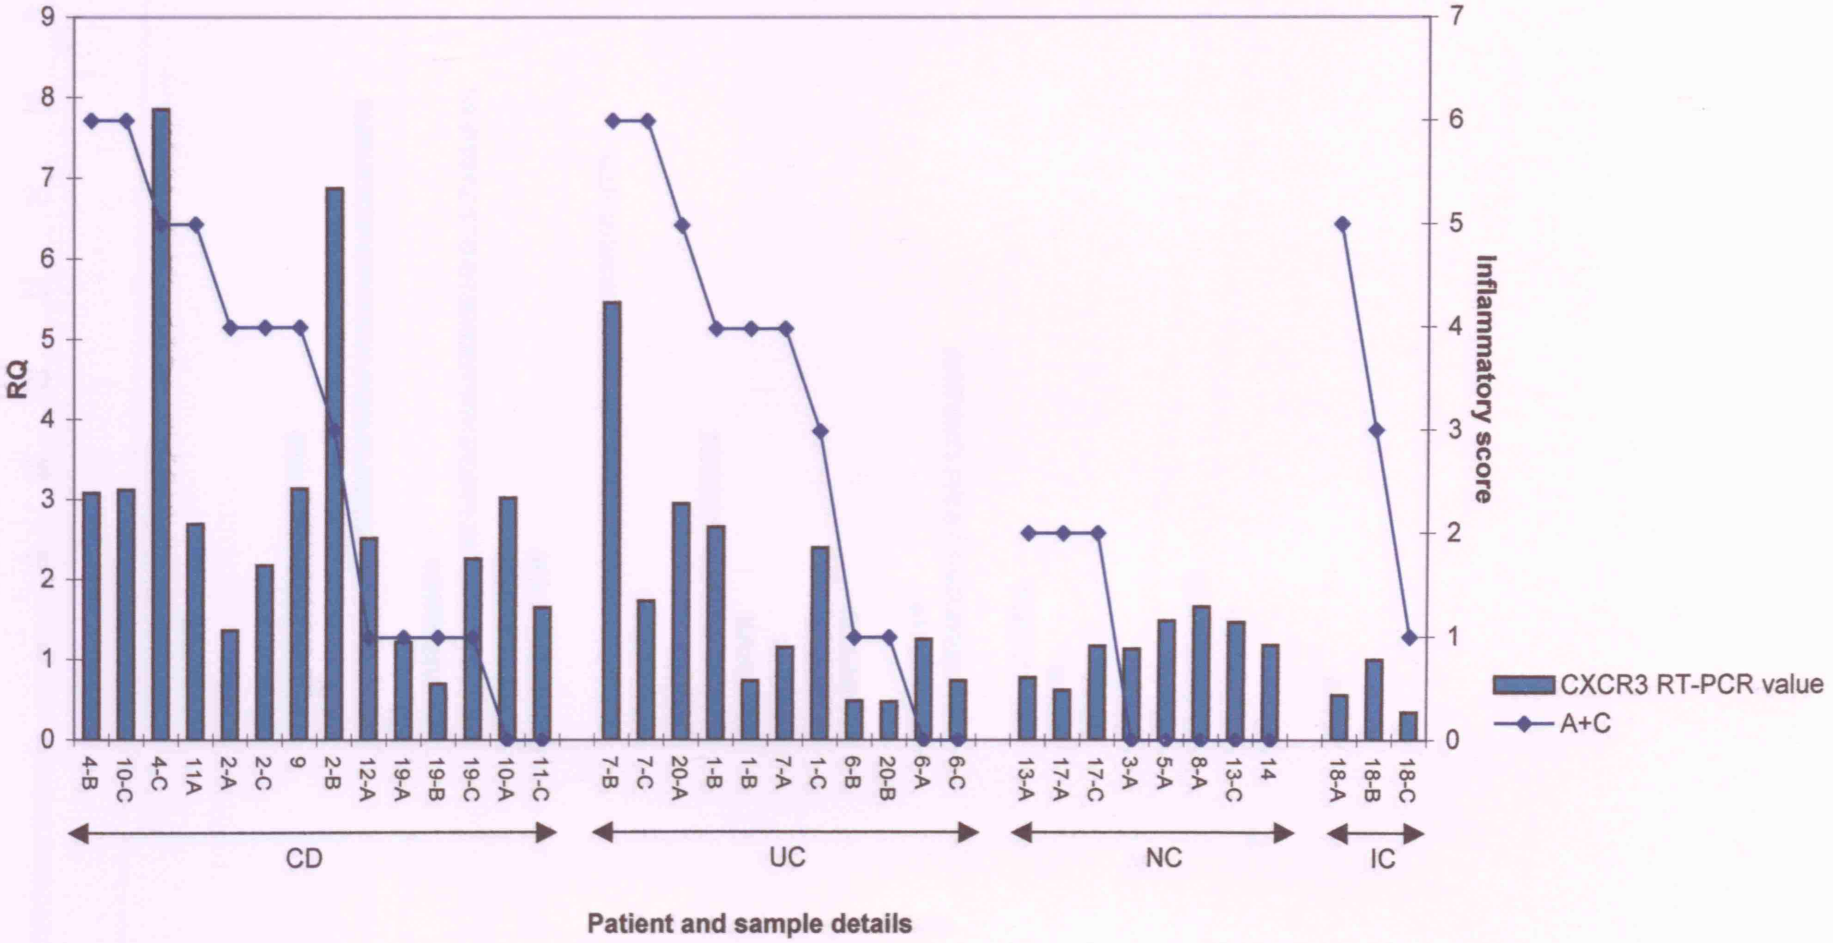
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammatory control.

Graph 3.49: Relative expression of CCL24 in full thickness colonic tissue measured by RT-PCR corrrelated with relative levels of inflammation as determined by histopathological analysis



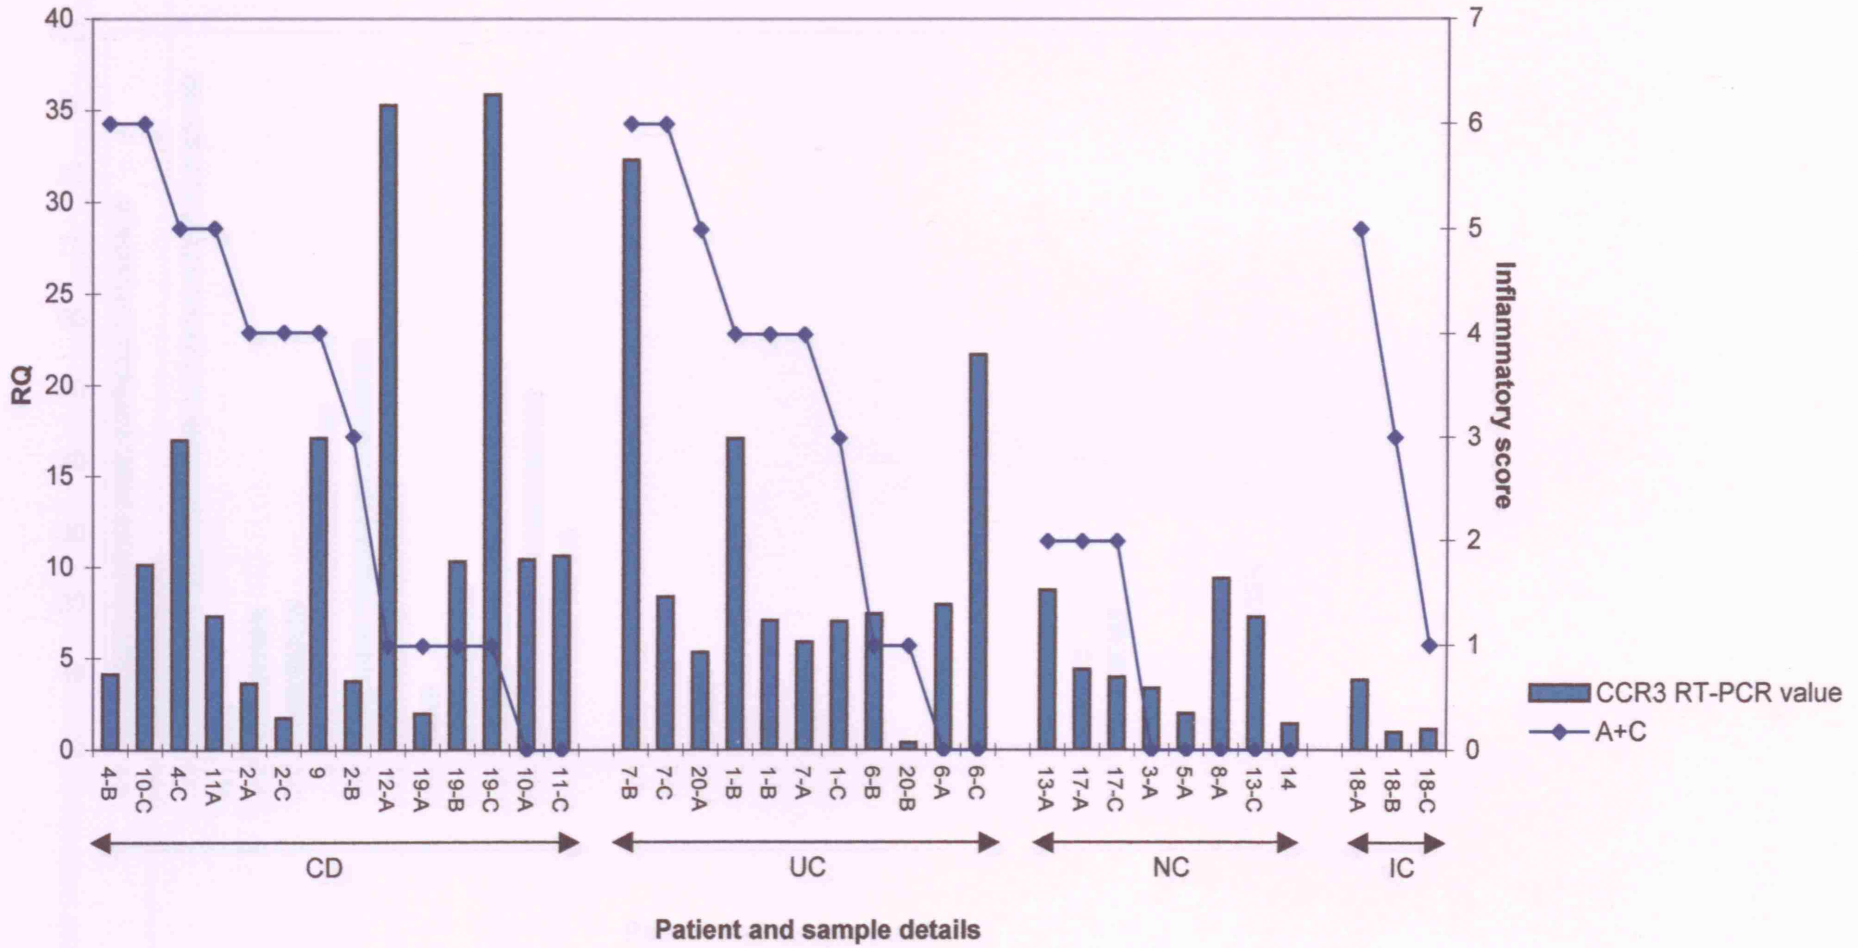
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammtory control.

Graph 3.50: Relative expression of CXCR3 in full thickness colonic tissue measured by RT-PCR corrrelated with relative levels of inflammation as determined by histopathological analysis



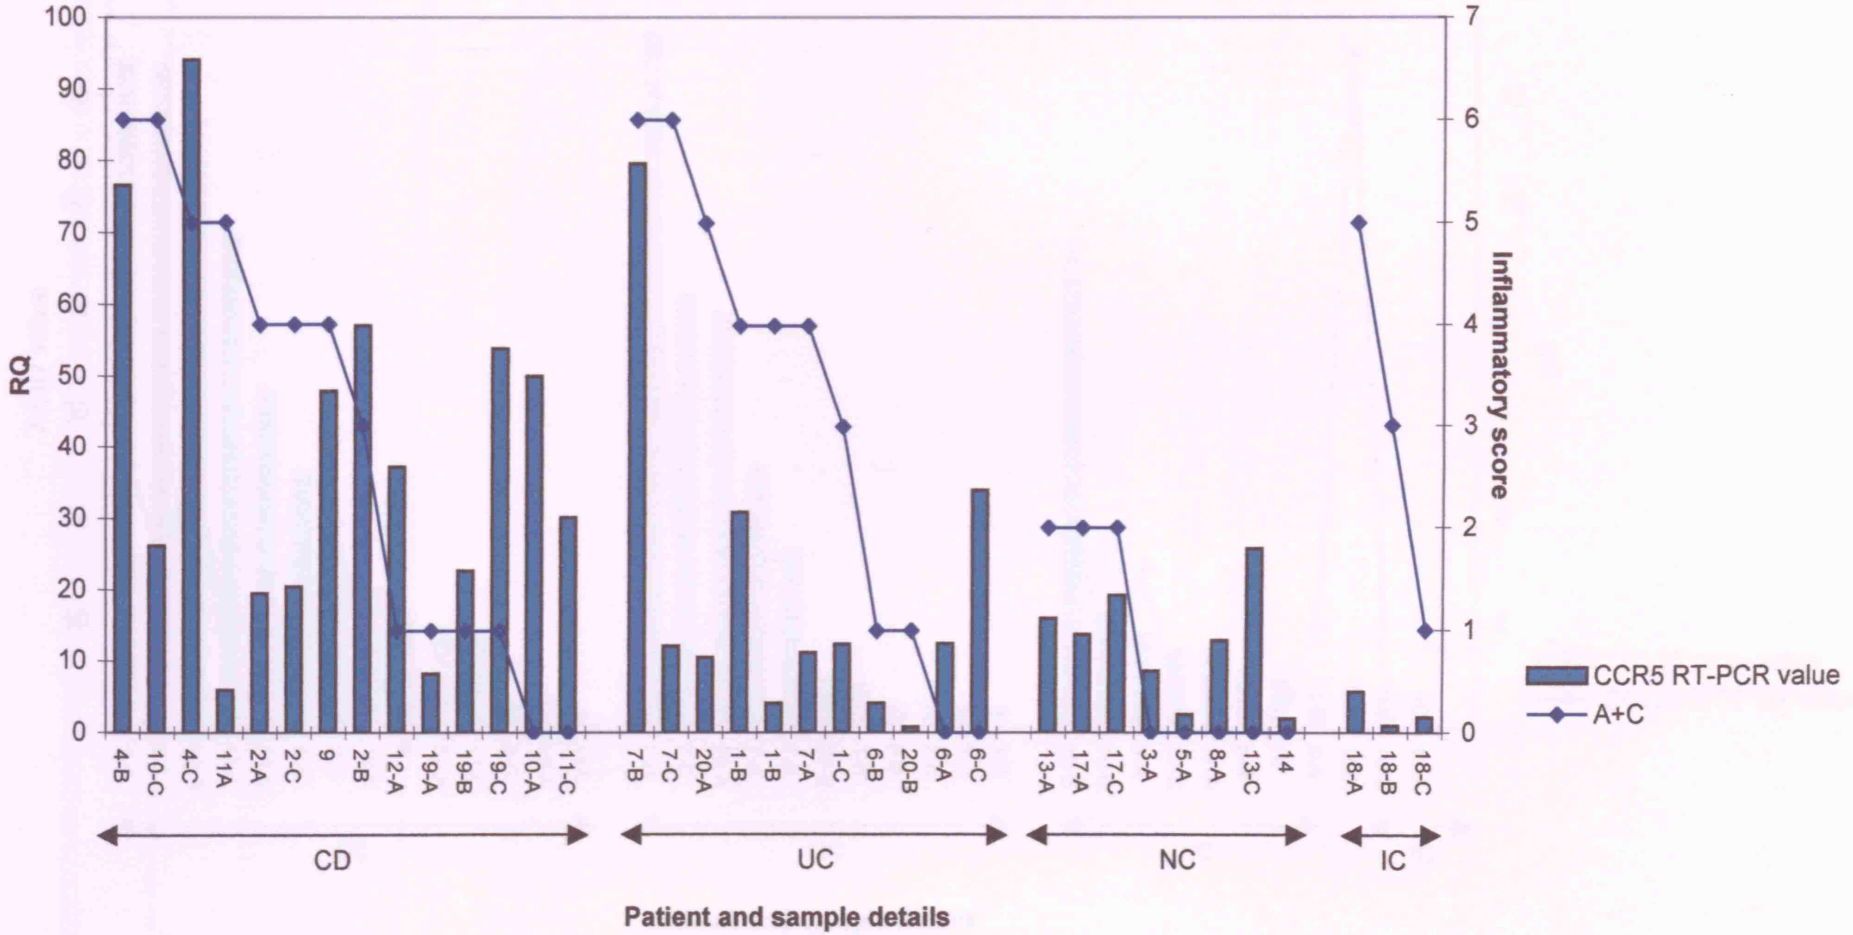
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammatory control.

Graph 3.51: Relative expression of CCR3 in full thickness colonic tissue measured by RT-PCR corrrelated with relative levels of inflammation as determined by histopathological analysis



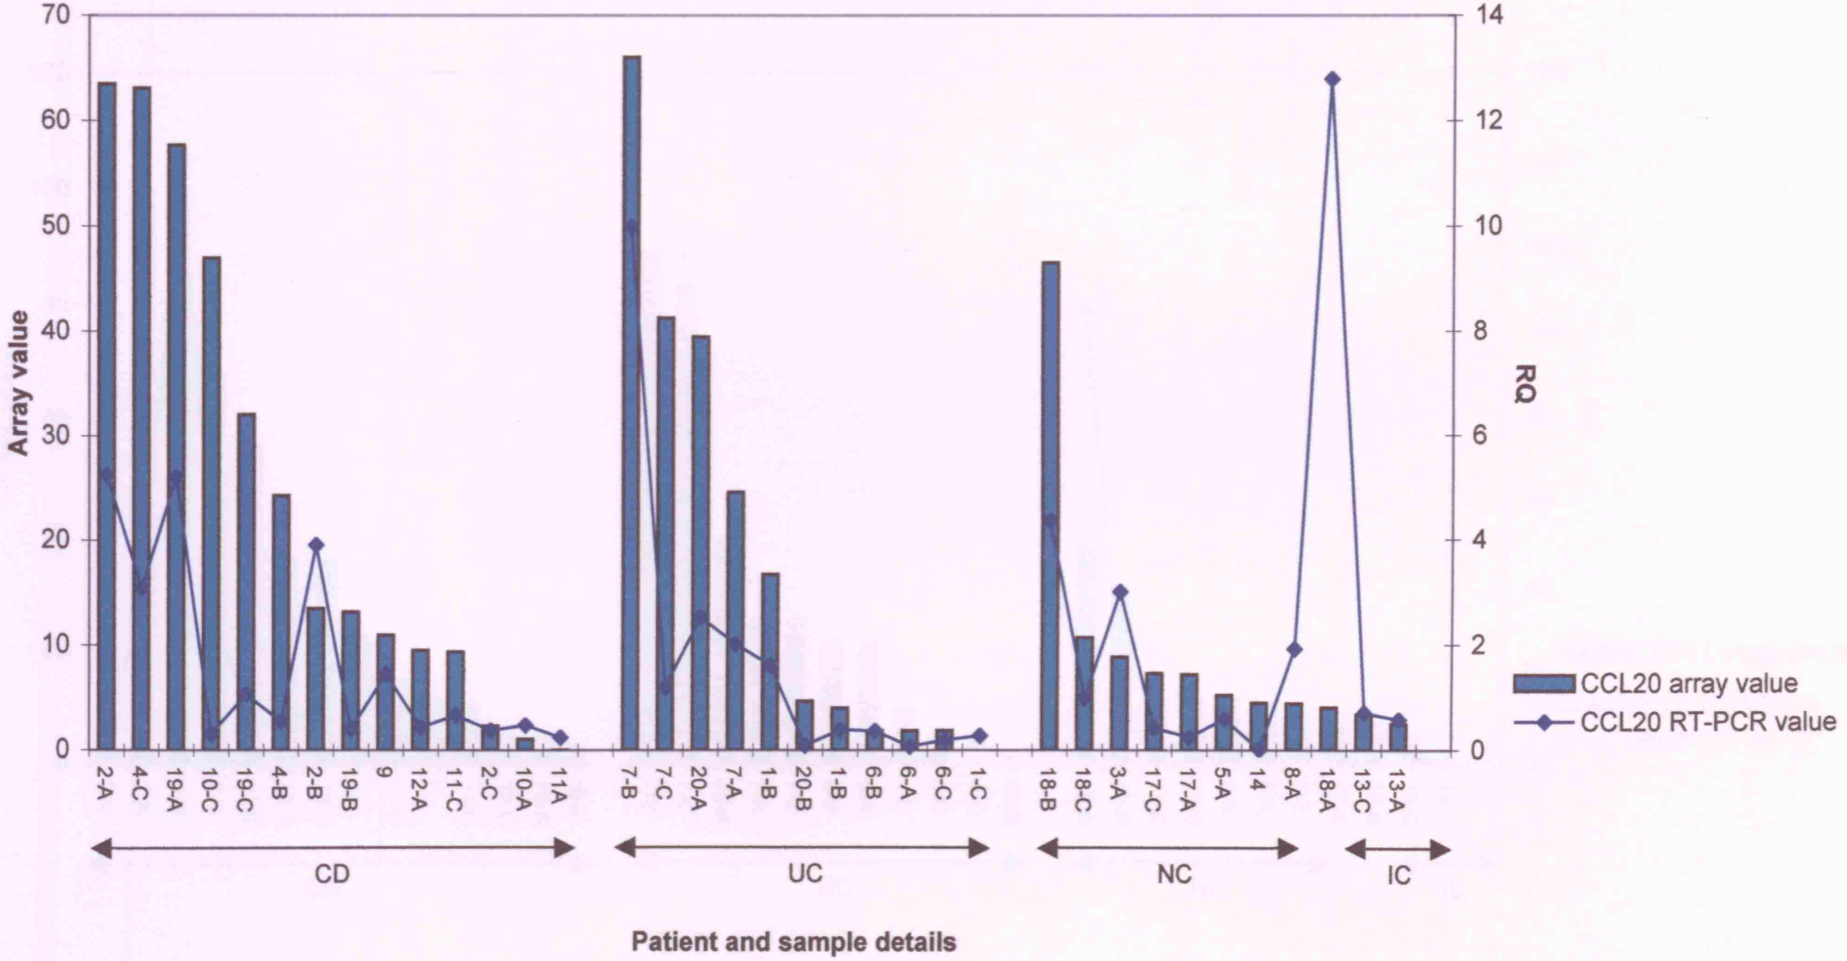
Patients are grouped according to disease, and chronologically placed according to inflammatory score A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammatory control.

Graph 3.52: Relative expression of CCR5 in full thickness colonic tissue measured by RT-PCR corrrelated with relative levels of inflammation as determined by histopathological analysis



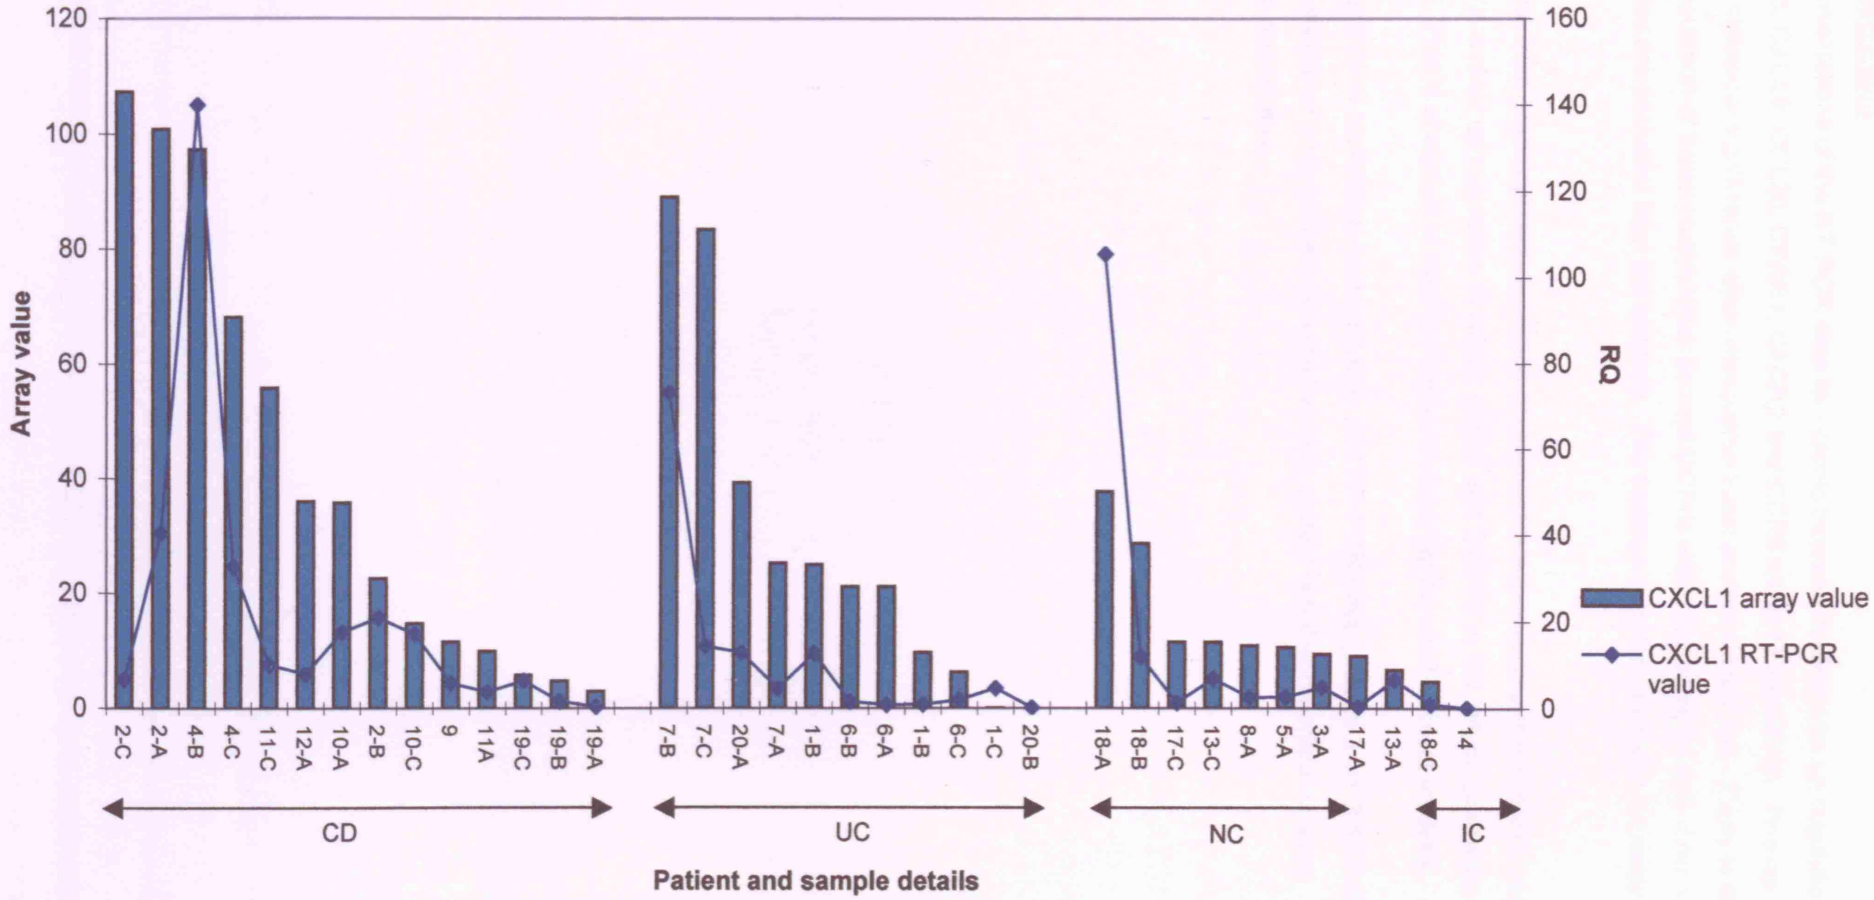
Patients are grouped according to disease, and chronologically placed according to inflammtory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammtory control.

Graph 3.53: Relative expression of CCL20 in full thickness colonic tissue measured by microarray corrrelated with relative expression of CCL20 measured by RT-PCR



Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammatory control.

Graph 3.54: Relative expression of CXCL1 in full thickness colonic tissue measured by microarray corrrelated with relative expression levels of CXCL1 measured by RT-PCR



Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C (as defined in table 2.3). Patient and sample details are outlined in appendix table 2. NC=normal control, IC=inflammatory control.

3.3.4 Discussion

Graphical representations of the RT-PCR data for colonic biopsies implicate an up regulation of CXCL1, CXCL3, CXCL8, CCL20, CXCR1, CXCR2 and CCR6 within UC samples. This up regulation is of statistical significance when non-paired t-test analysis is applied. There is also statistical up regulation of these chemokines (except CCR6) within CD samples only if the non-inflamed samples are excluded from the analysis. The findings correlate well with the array data.

Of particular note from graphical representation of chemokine expression within full thickness samples, there is a clear up regulation of CCL5, CCR5 and CXCR3 in CD, which correlates well with array data. This is of statistical significance when applying non-paired t-test analysis.

There is good graphical correlation between array and RT-PCR data (graphs 3.40, 3.52-3.53), although direct statistical analysis between the two sets of data is not appropriate as array values are semi-quantitative.

3.3.4 Discussion

There is good graphical correlation between array and RT-PCR data (graphs 3.40, 3.52-3.53), although direct statistical analysis between the two sets of data is not appropriate as array values are semi-quantitative.

3.4 Discussion

The technique of microarray profiling allows quantitative assessment of differential mRNA expression in situ, avoiding the amplification artefacts that may occur with RT-PCR studies. The effectiveness of the normalisation methodology is demonstrated by an even level of expression of the actin gene, independent of inflammation quotient (Graph 3.2). As the assessment is only semi-quantitative, confirmatory evidence from RT-PCR was necessary to validate the microarray data obtained. Quantitative RT-PCR generally confirms the correlation between transcriptional up regulation and level of inflammation observed in microarray experiments.

Overall the data provides a clear correlation between increasing expression of CXCL's1-3 and CCL20 with increasing acute and chronic inflammation quotient within the UC cohort, and to a lesser degree in the CD cohort. No samples in the non-IBD cohort exhibit significant up regulation of these chemokines. The variation in chemokine expression was not dependent on the anatomical origin of the biopsy. Real-time RT-PCR of colonic biopsy samples confirms the correlation between transcriptional up regulation and level of inflammation observed in microarray experiments. Statistical analysis from full thickness IBD sample RT-PCR data did not indicate a significant up regulation in CXCL's 1-3, CXCL8 and CCL20. This may well relate to drug treatment; the patients in the IBD biopsy cohort underwent colonoscopic examination for screening purposes, where as for the surgical resection cohort, the majority of patients had more active disease, and were almost all on some form of immunosuppressive agent. In the biopsy cohort, 1/8 UC and 2/6 CD patients were on immunosuppressive therapy, compared to 6/6 UC and 6/9 CD in the full thickness cohort (appendix 2.3 and 4.4).

CCL20 expression is of particular interest as this chemokine is specifically involved in mucosal immunity, particularly in human intestinal epithelium, where it induces local migration of dendritic cell subsets expressing the receptor CCR6. CXCL1 and its receptors CXCR1 and CXCR2 are thought to account for the initial destructive changes seen in UC, with a neutrophilic infiltration into the epithelium. The up regulated expression of CXCL's1-3 and CCL20 observed in inflamed UC colon biopsies was also noted in full-thickness UC samples, expression correlating with histopathological scoring for inflammation (graphs 3.23-3.35). However RT-PCR results for full thickness specimens did not reach levels of statistical significance. Overall, levels of CXCL's1-3 and CCL20 are generally lower than those seen from biopsy tissue which is likely to relate to a larger proportion of non-epithelial cells in comparison to biopsy samples, thus lowering the relative mRNA concentration of epithelial expressed genes. Data from array analysis of stripped epithelium and lamina propria is supportive of this, with higher expression of chemokines in the epithelial compartment, although direct conclusions are inappropriate on the basis of one patient.

Interestingly a number of CD samples also demonstrate the coordinated expression of CXCL's1-3 and CCL20 but independently of inflammation as judged by histological scoring. This is potentially due to the characteristically patchy nature of CD pathology, where even adjacent biopsies can show quite distinct focal inflammatory responses, and to the use of a histological

scoring index based on mucosal changes alone. The expression of CXCL's1-3 and CCL20 was enhanced in the full thickness specimens from CD patients in comparison to biopsies, suggesting origin within cells in the deeper layers.

Four specimens from a patient diagnosed with diverticulitis exhibited coordinated expression of CXCL's1-3 and CCL20, expression levels correlating with inflammatory quotient, suggesting that these are up regulated in gastrointestinal inflammation generally rather than IBD specimens.

Increased expression of CCL5 (RANTES) was observed in full thickness samples that was not detected at similar levels in any biopsy samples analysed in this study. These observations were confirmed using real-time quantitative RT-PCR and the analysis extended to the CCL5 receptor, CCR5. CCL5 and CCR5 are expressed at generally higher levels in the CD cohort than the UC and control cohorts, while no significant difference was found between UC and control. Levels of chemokine expression did not correlate with inflammatory quotient, again suggestive of the involvement of cells compartmentalised within the submucosa.

The levels of CXCL8 detected by the array were low in comparison to CXCL's 1-3, although there was an up regulation of this chemokine in inflamed UC and CD tissue. Both CXCR1 and CXCR2 act as receptors for the chemokines CXCL1 and CXCL8, whilst CXCR2 is also the receptor for CXCL2 and CXCL3 (Zlotnik et al, 2000). RT-PCR analysis did indicate an up regulation in each of these chemokines and receptors in inflamed IBD biopsy tissue.

Both CXCR1 and CXCR2 act as receptors for the chemokines CXCL1 and CXCL8, whilst CXCR2 is also the receptor for CXCL2 and CXCL3 (Zlotnik et al, 2000). CCR6 is a more unusual chemokine receptor in that it only binds a single chemokine, CCL20 (Yeung et al, 2000). As there was an observed up regulation in expression of CXCL's1-3, CXCL8 and CCL20, it is a reasonable assumption that cells expressing the cognate receptors for these ligands will be chemotactically recruited, resulting in a simultaneous detectable increase in receptor expression. Levels of transcript for these receptors were too low to be accurately detected by the array, so gene expression quantification by real-time RT-PCR was of value. In support of a functional role for this chemokine cluster in colonic IBD, the levels of expression for these receptors correlated well with both the expression of their cognate chemokines and scoring for inflammation in biopsy tissue. Within the specific cluster, several UC samples also exhibited expression of the CCR7 binding chemokines, CCL19 and the CXCR5 binding chemokine, CXCL13. CCR7 enable dendritic cells to be guided into draining lymph nodes by the lymphoid chemokine CCL21, the ligand for CCR7 (Nakayama et al, 2001). These antigen-presenting cells are crucial for the initiation of an immunological response, activating naïve T and B cells, which return to the site of inflammation. As homeostatic trafficking of B and T lymphocytes and dendritic cells into secondary lymphoid tissue is predominantly mediated by these chemokines, and organised lymphoid aggregates in the deep lamina propria are characteristic of UC, expression of these three chemokines presumably indicates the presence of lymphoid tissue within these particular biopsies (Baba et al, 1997), (Lindhout et al, 1999), (Yeung et al, 2000). However, this cannot be confirmed as histology was performed on adjacent biopsies. Taken together, these data lead to the proposal that gene expression of this defined chemokine subset consisting of CXCL1,

CXCL2, CXCL3, and CCL20 may be closely related to inflammatory events occurring in the colon of IBD subjects.

Chapter 4

Immunohistochemical localisation and quantification of CCR6, CCL20, CXCR1 and CXCR2, using the immunoperoxidase technique

4.1 Background

4.2 Immunohistochemical localisation CCL20 using the immunoperoxidase technique

- 4.2.1 Optimisation of pre-treatment method using appendix sections
- 4.2.2 Titration of primary antibody and finalisation of optimal pre-treatment method, using appendix and colonic surgical sections
- 4.2.3 Use of established immunohistochemistry technique on colonic biopsy sections
- 4.2.4 Titration of link antibody using colonic biopsy sections, and finalisation of pre-treatment method
- 4.2.5 Immunohistochemical localisation and scoring of CCL20 on colonic biopsy series

4.5.1 Optimisation of pre-treatment method using surgical colonic and appendix sections

4.5.2 Titration of primary antibodies using colonic biopsy sections

4.5.3 Immunohistochemical localisation and scoring of CXCR2 on colonic biopsies

4.6 Discussion

4.1 Background

Analysis of the microarray and PCR data indicated that a distinct subset of chemokines, consisting of CXCL's 1-3 and 8 and CCL20, was up regulated in active colonic IBD, compared to non-inflamed areas and tissue from controls. In order to confirm gene expression levels as determined by RNA analysis, immunohistochemical studies were undertaken to determine protein expression of CCL20, CCR6, CXCR1 and CXCR2 in adjacent biopsies. The immunoperoxidase technique used is described in section 2.2.4.

4.2 Immunohistochemical localisation of CCL20 using immunoperoxidase technique

The CCL20 antibody had not been previously tested for immunohistochemical studies on paraffin-embedded tissue, so a series of experiments were undertaken to determine optimal experimental conditions. The CCL20 antibody used was a goat antibody species, which necessitated use of a biotinylated rabbit anti-goat secondary antibody. In place of NHS, normal rabbit serum was used.

4.2.1 Optimisation of pre-treatment method using appendix sections

Aim: To establish the optimal link antibody pre-treatment method.

Tissue sections: 3μm sections of appendix tissue were used, prepared as standard.

Immunohistochemical staining: The sections were incubated 1 hour in the primary anti-CCL20 antibody at a dilution of 1/50 (2μg/ml), as recommended by the manufacturer.

Results: The 2 optimal pre-treatments methods were pressure cooker treatment with EDTA for 90 seconds and high-powered microwave treatment in citrate buffer for 25 minutes. There was immunohistochemical staining with CCL20 at 1/50 dilution (2μg/ml), although this was not clearly distinguishable from background staining. Furthermore, the genuine staining quite weak. Further work was required to elucidate optimal antibody dilution.

Conclusion: This initial experiment established 2 optimal pre-treatment preparations of the link conjugates for use in subsequent experiments, which were pressure cooker treatment in EDTA and high-powered microwave treatment in citrate buffer for 25 minutes. Due to inadequate genuine uptake with excessive background staining, primary antibody incubation was extended to overnight with the addition of a blocking agent.

4.2.2 Titration of link antibody and finalisation of optimal pre-treatment method, using appendix and colonic surgical sections

Aims: This experiment was designed to further optimise the pre-treatment method, the primary antibody dilution and application of a blocking agent. The pre-treatment methods used were those identified to be optimal in the previous experiment.

Methods: The tissue sections, blocking agents, pre-treatment methods and primary antibody dilutions are listed in table 4.1. The sections were incubated overnight (approximately 18 hours) at +4°C in a humidity chamber.

Results: The optimal pre-treatment method was pressure cooker treatment in EDTA for 90 seconds, at a dilution of 1/50 (2μg/ml), with inclusion of FCS as a blocking agent. Microwave treatment for 25 minutes in citrate buffer also gave similar staining, although not as strong.

Conclusion: The optimal pre-treatment, dilution and blocking agent had been established.

Table 4.1: List of sections, pre-treatments methods, primary antibody dilutions and blocking agents used in immunoperoxidase immunohistochemical optimisation for CCL20, as outlined in 4.2.2.

Surgical section	Pathology	Pre-treatment	Primary antibody dilution	Primary antibody solution	Blocking agent
Colon	UC	PC(EDTA)	Nil (control)	Nil	Nil
Colon	UC	PC(EDTA)	1/100 (1μg/ml)	2μl ab / 400μl TBS	Nil
Colon	UC	PC(EDTA)	1/100 (1μg/ml)	2μl ab + 20μl FCS/400μl TBS	FCS

4.2.3 Use of established immunohistochemical technique on colonic biopsy sections

Aims: The experiment was designed to use the CCL20 primary antibody at the established optimal dilution of 1/50 (2μg/ml), with the optimal pre-treatment method of pressure cooker EDTA or microwave cooking in citrate buffer, on colonic biopsy sections.

Methods: Tissue sections: 2 x 3μm paraffin embedded, formalin-fixed colonic biopsy tissue sections were used, from each of 3 patients: 1 with UC, 1 with CD, and 1 with no disease (control). In addition, 2 sections were used for control negative without primary antibody incubation. The sections were prepared as standard.

Immunohistochemistry technique: The pre-treatment method of 90 seconds of pressure-cooking treatment immersed in EDTA. Blockade of endogenous peroxide activity was achieved by of FCS in TBS buffer. The sections were incubated in the primary antibody overnight (approximately 18 hours) at +4°C in a humidity chamber, at a dilution of 1/50 (2μg/ml).

Results: Although the optimal dilution was found to be between 1/50 (2μg/ml) for surgical colonic sections, for these biopsy sections this dilution led to over-staining, with inadequate discernible difference between the cases.

Conclusion: A 1/50 dilution (2μg/ml) was too concentrated for colonic biopsy tissue.

4.2.4 Titration of link antibody using colonic biopsy sections, and finalisation of pre-treatment method

Aims: To optimise the primary antibody dilution in colonic biopsy tissue.

Methods: Tissue sections: 3μm paraffin embedded; formalin-fixed colonic biopsy tissue sections were used, from patients with UC and with no disease i.e. normal controls.

Immunohistochemistry technique: The 2 antigen retrieval methods used were microwave treatment 25 minutes in citrate buffer or pressure cooking treatment in EDTA. The primary antibody dilution was varied from1/65 (1.54μg/ml) to 1/100 (1μg/ml). FCS was used throughout as a blocking agent. The sections were incubated overnight (approximately 18 hours) at +4°C in a humidity chamber.

Results: The optimal pre-treatment condition was high-powered microwave treatment for 25 minutes in citrate buffer, at a primary antibody dilution of 1/65 (1.54μg/ml).

Conclusion: The optimal conditions have been established for staining of the CCL20 chemokine for colonic biopsies. These constitute high-powered microwave cooking in citrate buffer for 25 minutes, with an antibody dilution of 1/65, (1.54μg/ml) with a 5% FCS at the initial blocking step, primary antibody solutions, in addition to the secondary and tertiary dilutions.

4.2.5 Immunohistochemical localisation and scoring of CCL20 on colonic biopsy sections

Aims: Previous experiments had established the optimal conditions for staining of the CCL20 chemokine on colonic biopsies. These conditions were used on the study colonoscopic biopsies.

Methods: Tissue sections: 3μm paraffin-embedded, formalin-fixed colonic biopsy tissue sections used from the 10 patients: a total of 18 biopsies from patients with UC, 18 CD, 18 with no disease (normal control), from adjacent sites as those taken for microarray analysis. Sections were included from control patients 2, 6, 7, 13; from UC patients 14, 15, 16; and from CD patients 8, 11, 26, prepared as standard. The subset was chosen on the basis of the previous microarray data. Patient details are outlined in appendix table 2.3.

Immunohistochemistry technique: The optimal pre-treatment method of 25 minutes high-powered microwave was used. Blockade of endogenous peroxide activity was achieved by incubation in a 5% FCS solution in TBS buffer. 1/65 (1.5mg/ml) primary antibody in TBS buffer was applied, with 5% FCS. Sections were incubated overnight (18 hours approximately) at +4 °C in the primary ant-CCL20 antibody, in a humidity chamber.

Scoring: A semi-quantitative score from 0 (none) to 4 (dense confluent staining) was determined for epithelium, and percentage immunoreactive lamina propria cells determined (0=0%, 1= 25 %, 2=50%, 3=75%, 4=100%). The scoring was performed under blind conditions, whereby the slide identity was concealed, and all the slides were allocated a number randomly. Unblinding only took place when all the scoring was complete. The scores are listed in table 4.2. Once scoring reliability had been ensured statistically, the original scores were correlated with both microarray data and histopathology inflammation scores. For each biopsy, a corresponding biopsy from the

same area had been assessed by a consultant histopathologist, and scored on the basis of inflammation as detailed in appendix table 1.

Table 4.2: CCL20 immunohistochemistry scores for the colonic biopsy series, inflammatory scores and gene expression levels as determined by TaqMan real-time quantitative PCR values.

Statistical validation: As the scoring was semi-quantitative, it was important to statistically validate the scoring technique consistency and reliability. 11 slides were re-scored for all parameters, blind from the slide identity and the original score. Each value was paired with the initial scoring value. These pairs were incorporated into a student's t-test for paired parametric

data. Each of the first scores for 11 slides was paired with the corresponding second scores, as listed in table 4.3. This statistical test is useful for investigating a variable in two groups where there is a meaningful one-to-one correspondence between the data points in one group and those in the other. The null hypothesis states that there is no significant difference between the 2 groups.

Table 4.3: List of initial and repeat semi-quantitative immunohistochemistry scores for CCL20, to demonstrate reproducibility of scoring method.

Table 4.4: Values for statistical validation of CCL20 immunohistochemistry scores

Values	X_a	X_b	$X_a - X_b$
n	58	58	58
Sum	119.	116.5	3
Mean	2.0603	2.0086	0.0517
Sum_sq	277.75	264.25	3.5
SS	31.5388	30.2457	3.3448
Variance	0.5533	0.5306	0.0587
Standard Deviation	0.7838	0.7284	0.2422

$Mean_A - Mean_B = 0.0517$

$t = -1.63$, $df = 57$

Two-tailed $p = 0.109599$

On the basis of this $p>0.05$, the null hypothesis cannot be rejected, i.e. that there is no statistical difference between the original and repeat scoring values. Thus, the scoring reducibility is acceptable.

Results: The immunohistochemical scores are listed in table 4.2. There was no staining on the negative slides, where the primary antibody had been omitted (figure 4.1a). Weak epithelial staining is seen in control section, while stronger immunoreactivity is seen in both CD and UC, with increased density of subepithelial $CCL20^+$ cells (figures 4.1 b-d). Of 17 normal control *biopsies, 2 showed enhanced expression of CCL20 in crypt epithelium (score >2), compared to 11/16 UC and 6/15 CD specimens (4.1 c, g, h, I, j). Similar increase was seen in CCL20 expression in surface epithelium (1/17 control biopsies, 10/16 UC and 6/15 CD). There were some positive staining in sub-epithelial macrophages and intraepithelial lymphocytes. Lymphocytic staining was patchy. Occasional neutrophils stained, though not as strongly as for CCR6 (figures 4.1 k, l). $CCL20^+$ lamina propria cell density exceeded 50% of total cells in 2/17 controls, 12/16 UC and 12/15 CD (4.3 b, c, d, g, I, j).

Non-parametric correlation analyses between CCL20 immunohistochemical scores and corresponding RT-PCR values indicated a fair association. Spearman's correlation coefficients were as follows: 0.33* (p=0.023) for lamina propria, 0.31* (p=0.032) for surface epithelium, 0.38* (p=0.008) for crypt epithelium (illustrated below) and 0.38* (p=0.009) for vascular endothelium (* indicates statistical significance).

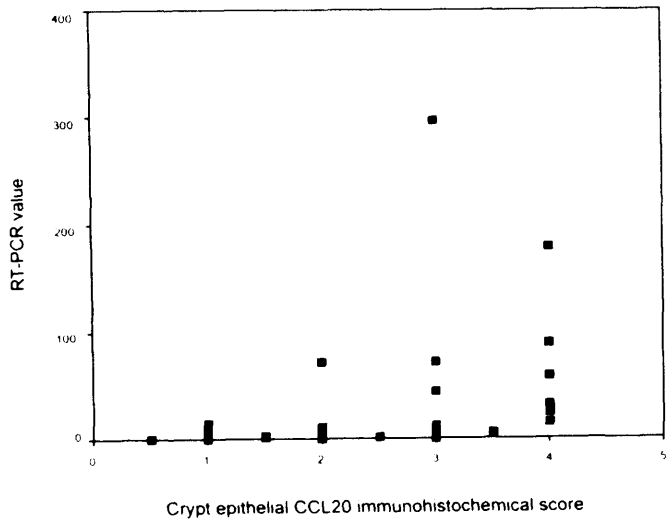

Figure 4.1: Colonic immunohistochemical staining for $CCL20^{+}$ cells using the immunoperoxidase technique. 4.1(a): Negative i.e. no primary antibody added, original magnification x10. 4.1(b): Normal control, original magnification x40. 4,1(c), (d), (e): UC, original magnification x 20 (c), x40 (d), (e).

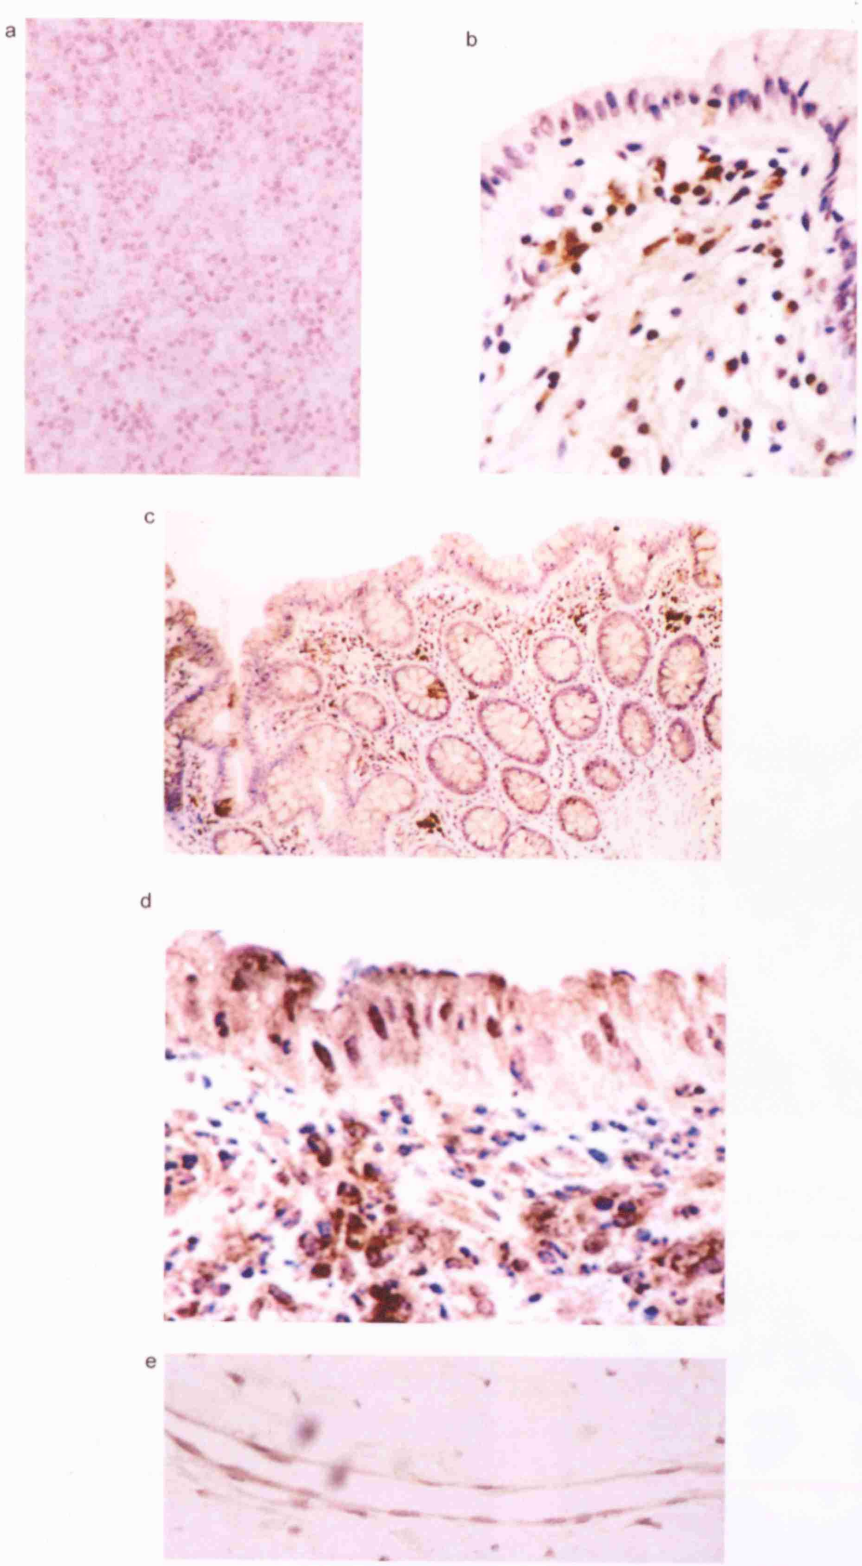

Figure 4.1: Colonic immunohistochemical staining for $CCL20^{+}$ cells in CD, using the immunoperoxidase technique. Original magnification x40 for (i), (j), (l) x20 for (f), (h), (k), x10 for (g). Neutrophilic staining is demonstrated in (k) and (l).

4.3 Immunohistochemical localisation of CCR6 using the immunoperoxidase technique

As this antibody had not been previously tested for immunohistochemical studies on paraffin-embedded tissue, a series of experiments were carried out to optimise conditions.

4.3.1 Optimisation of pre-treatment method using appendix sections

Aim: To establish optimum pre-treatment for horseradish peroxidase immunohistochemistry using a monoclonal CCR6 antibody.

Tissue sections: 3μm paraffin-embedded, formalin-fixed appendix tissue sections were used.

Immunohistochemical technique: Non-inflamed appendix tissue sections were ustilised, and NHS was incorporated as the blocking agent. The primary antibody was applied at a 1/25 dilution, i.e. 20μg/ml (64μl antibody in 1600μl TBS). The sections were incubated for 1 hour at room temperature in a humidity chamber at room temperature.

Results: There were 2 pre-treatment conditions that led to a higher quality of staining; 90 seconds in a pressure cooker immersed in EDTA, and the 25 minutes in a microwave (high power) in citrate buffer. However, although these 2 conditions were definably better, the slides were over stained. There was considerable background staining at the recommended dilution of 1/25 (20μg/ml).

Conclusion: This initial experiment established 2 optimal pre-treatment preparations of the link conjugates for use in subsequent experiments.

4.3.2 Titration of primary antibody using appendix sections

Aims: This experiment was designed to optimise the link CCR6 antibody dilution, using the pre-treatment methods selected in the previous experiment.

Tissue sections: 3μm paraffin-embedded, formalin-fixed appendix tissue sections were used.

Immunohistochemical technique: The optimal pre-treatment methods of 90 seconds in the pressure cooker immersed in EDTA or 25 minutes in citrate buffer in a microwave on high power were used. The sections were incubated in the primary antibody, at the dilutions ranging from 1/100 (5μg/ml) to 1/8000 (62.5ng/ml). The ensuing conditions were otherwise unchanged.

Results: The optimal dilution was found to be 1/1000 i.e. 0.5μg/ml, with background staining increased at higher concentrations and loss of specific staining at less than 1/2000 (i.e. 0.25μg/ml).

Conclusion: The results from the previous experiment enabled establishment of the optimal pre-treatment preparation of pressure cooker EDTA or microwave in citrate buffer. The results from this experiment implicated the optimal antibody dilution for CCR6 to be 1/1000 (0.5μ/ml) for appendix tissue.

4.3.3 Use of established immunohistochemical technique on colonic sections

Aims: This experiment was designed to establish which pre-treatment method enabled the optimal staining: pressure cooker treatment in EDTA or microwave cooking in citrate buffer. The CCR6 antibody was utilised at a dilution of 1/1000 (0.5μg/ml), on colonic biopsy sections.

Methods: Tissue sections: 2 x 3μm paraffin embedded, formalin-fixed colonic biopsy tissue sections used, from each of 3 patients: 1 with UC, 1 with CD, and 1 with no disease (control). In addition 2 slides were used as control negative, with no primary antibody.
Results: Although the optimal dilution was found to be between 1/1000 (0.5μg/ml) with surgical appendix sections, with these colonic sections there was over-staining, and little discernible difference between the cases, with marked over staining.
Conclusion: Previous experiments established the optimal pre-treatment preparation of pressure cooker treatment in EDTA or microwave 25 minutes, of the link conjugates for use in subsequent experiments, at a dilution of 1/1000 (0.5μg/ml) for appendix tissue. This experiment indicated that the optimal dilution for CCR6 staining was less this for colonic tissue, and further studies were needed.

4.3.4 Titration of link antibody using colonic sections, and finalisation of pre-treatment method

Aims: This experiment was designed to establish the optimal pre-treatment method and CCR6 antibody dilution specifically for colonic biopsies. Results from previous experiments indicated that the 2 optimal pre-treatment methods were pressure cooker in EDTA or high-powered microwave treatment for 25 minutes in citrate buffer. Analysis of results from experiment 4.3.3 also indicated that a dilution of less than 1/1000 (0.5μg/ml) was appropriate.
Tissue sections: 3μm paraffin embedded, formalin-fixed colonic biopsy tissue sections from patients with UC/control (i.e. no disease) were used. Appendix and splenic sections were also included.
Immunohistochemical technique: The optimal pre-treatment methods of 90 seconds in the pressure cooker immersed in EDTA or microwave treatment in citrate buffer on high power for 25 minutes were used. The blocking agent used was NHS, milk powder or FCS. The primary antibody dilution used varied from 1/2000 (0.25μg/ml) to 1/4000 (0.125μg/ml).
Results: The optimal pre-treatment method was high-powered microwave treatment in citrate buffer, with a primary antibody dilution of 1/3000 i.e. 0.167μg/ml.
Conclusion: The optimum conditions have been established for staining of the CCR6 chemokine for colonic biopsies i.e. high-powered microwave treatment in citrate buffer for 25 minutes. The optimal primary antibody dilution was 1/3000 (0.167μg/ml), with a 5% FCS at the initial blocking step, primary antibody solutions, in addition to the secondary and tertiary dilutions.

4.3.5 Immunohistochemical localisation and scoring of CCR6 on colonic biopsies

Aims: Previous experiments had established the optimum conditions for staining of the CCR6 chemokine on colonic biopsies, i.e. high-powered microwave cooking in citrate buffer for 25 minutes. The optimal antibody dilution was found to be 1/3000 (0.17μg/ml), with a 5% FCS at the initial blocking step, primary antibody solutions, in addition to the secondary and tertiary dilutions. This technique was used on a subset of colonic biopsy series, chosen on the basis of the previous microarray data.
Tissue sections: 3μm paraffin embedded, formalin-fixed colonic biopsy tissue sections used from the 10 patients, from control patients 2, 6, 7; 13; from UC patients 14, 15, 16; and from CD

8, 11, 26. In addition, 2 negative controls were included. Patient details are outlined in appendix table 2.3.

Immunohistochemical technique: The optimal pre-treatment method of high-powered microwave cooking for 25 minutes was used.

Scoring: A semi-quantitative score from 0 (none) to 4 (dense confluent staining) was determined for epithelium, and percentage immunoreactive lamina propria cells determined (0 = 0%, 4 = 100%). The scoring was performed under blind conditions, whereby the slide identity was concealed, and all the slides were allocated a number randomly. Unblinding only took place when all the scoring was complete. In some slides, the blood vessels could not be identified clearly, so this score was omitted where necessary. The scores obtained are listed in table 4.5. Once scoring reliability had been ensured statistically, the original scores were correlated with both microarray data and histopathology inflammation scores. For each biopsy, a corresponding biopsy from the same area had been assessed by a consultant histopathologist, and scored on the basis of inflammation as detailed in table 2.2.

Table 4.5: CCR6 immunohistochemistry semi-quantitative assessment scores for the colonic biopsy series, with histopathological inflammatory scores and gene expression levels as determined by taqman real-time quantitative RT-PCR values.

Patient	Biopsy number	Lamina propria	Lymphoid	Surface epithelium	Crypt epithelium	Vascular	A+C	RT-PCR value

Statistical validation: As the scoring was semi-quantitative, it was important to statistically validate the scoring technique consistency and reliability. 11 slides were re-scored for all parameters, blind from the slide identity and the original score. Each value was paired with the initial scoring value. These pairs were incorporated into a student's t-test for paired parametric data. Each of the first scores for 11 slides was paired with the corresponding second scores, as listed in table 4.6. This statistical test is useful for investigating a variable in two groups where there is a meaningful one-to-one correspondence between the data points in one group and

those in the other. The null hypothesis states that there is no significant difference between the 2 groups.

Table 4.6: List of initial and repeat semi-quantitative immunohistochemistry scores for CCR6, to demonstrate reproducibility of scoring method.

Table 4.7: Statistical validation table of CCR6 semi-quantitative immunohistochemistry scores.

Values	X_a	X_b	$X_a - X_b$
n	63	63	63
Sum	189.5	195	-5.5
Mean	3.0079	3.0952	-0.0873
Sum_sq	612.75	642.5	15.75
SS	42.746	38.9286	15.2698
Variance	0.6895	0.6279	0.2463
Standard Deviation	0.8303	0.7924	0.4963

$Mean_A - Mean_B = -0.873$

$t = -1.4$

$df = 62$

Two-tailed $p = 0.167619$

On the basis of this $p>0.05$, the null hypothesis cannot be rejected, i.e. that there is no statistical difference between the original and repeat scoring values. The scoring reducibility is therefore not un-acceptable statistically.

Results: There was no staining in the control negative slides, where no primary antibody had been applied, demonstrated in figure 4.2a. In areas of inflammation a population of lymphocytes stained in the pericellular area (figure 4.2 e,f). More lymphocytic $CCR6^+$ staining was evident in IBD cases. Lymphoid areas were consistently strongly stained, corresponding primarily to the T-areas (4.2b). Neutrophils stained strongly, corresponding to inflammatory areas (figure 4.2 g, h, i,). There was moderate vascular staining and variable surface and crypt epithelial staining, particularly on the basolateral layer. Generally, control immunoreactivity was more pronounced on the surface than crypt epithelium. Both UC and CD showed stronger immunoreactivity of both surface and crypt epithelium. The $CCR6^+$ cells were more dense in the upper third of the lamina propria, and subjacent to the epithelium (figure 4.2 c,d). Clear differences were apparent in the deeper lamina propria area between cases of IBD and control, although the differences were subtler in the subepithelial area, with $CCR6^+$ cells extending to the deeper lamina propria (figure 4.2c, d, f). An occasional dendritic cell was evident in the subepithelial area. Muscular tissue was consistently unstained.

Formal quantisation of the staining is listed in table 4.5, and graphically represented in figure 4.4. Slides from patients with IBD had higher deeper-lamina propria scores than the control group, with lymphocytes staining particularly. There were more than 50% of total cells $CCR6^+$ in 1/17 controls, 13/16 UC and 12/15 CD. The scoring correlated with the histological inflammatory score as described before, and with mRNA expression from array data.

Non-parametric correlation analyses between CCR6 immunohistochemical scores and corresponding RT-PCR did not indicate an association. Spearman's correlation coefficients were as follows: 0.11 (p=0.43) for lamina propria, -0.039 (p=0.79) for surface epithelium, 0.020 (p=0.89) for crypt epithelium and 0.018 (p=0.91) for vascular endothelium.

Figure 4.2a-f: Colonic immunohistochemical staining of $CCR6^{+}$ cells using the immunoperoxidase technique. Original magnification x10 for (a) and (b), x20 for (c), (d), and (f) x40 for (e). A control negative is demonstrated in (a) where no primary antibody was applied. Appendiceal section immunostaining is demonstrated in (b). Control tissue immunostaining is demonstrated in (c), CD tissue in (d), and UC tissue in (e) and (f).

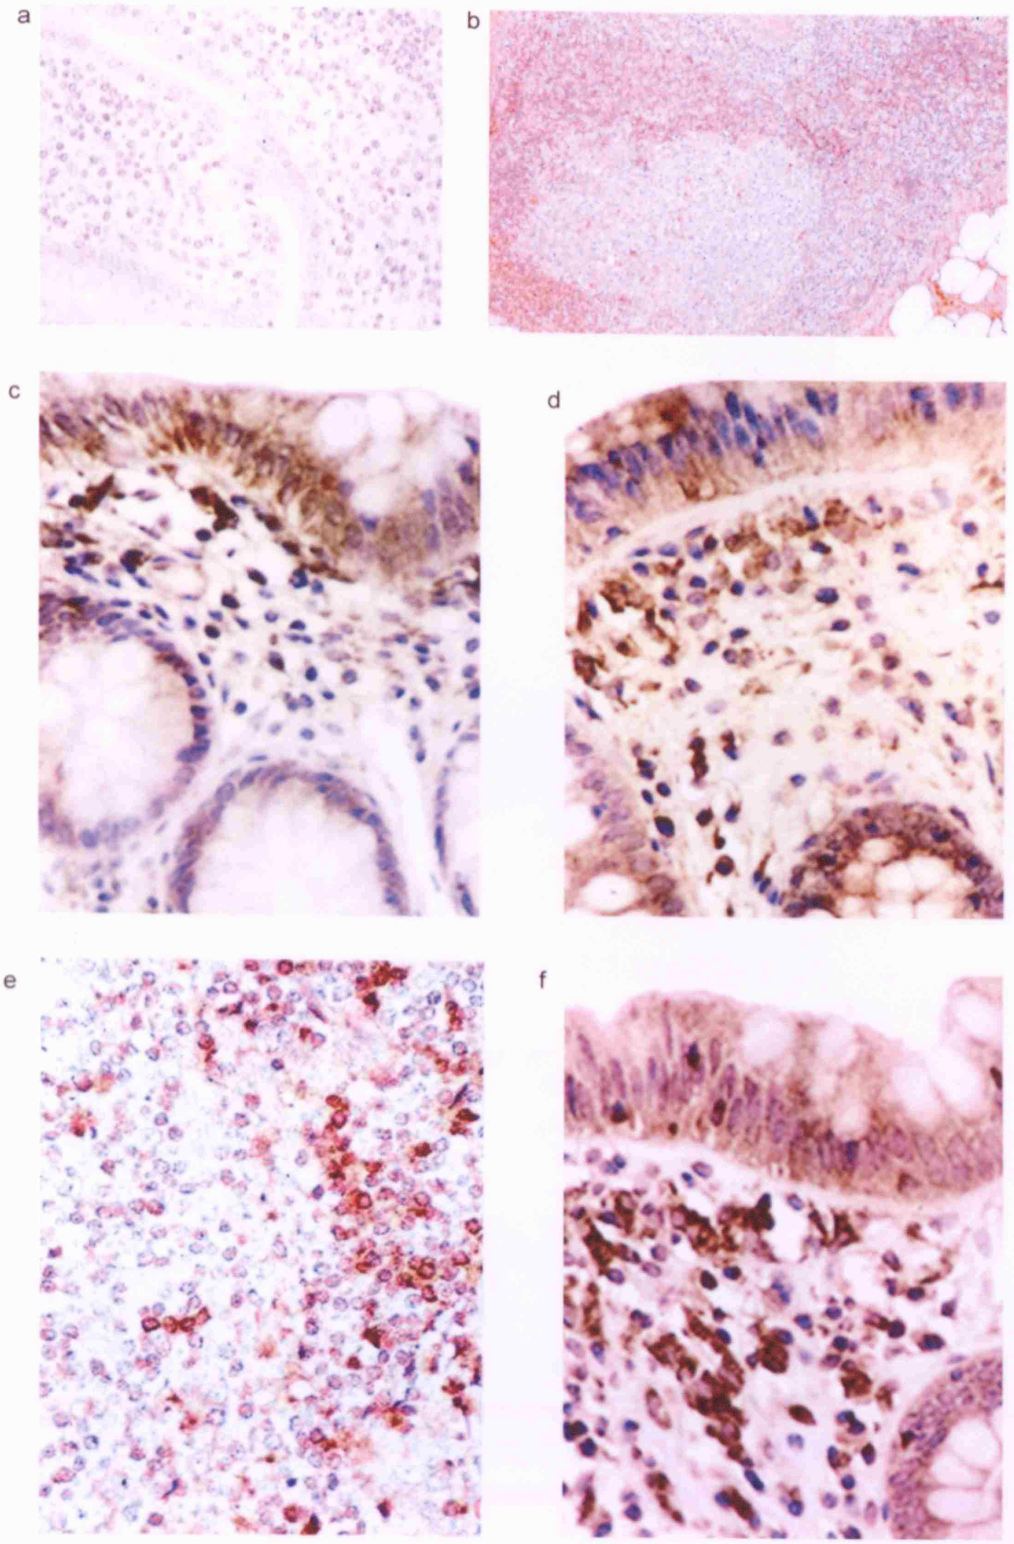

Figure 4.2g-l: Colonic immunohistochemical staining of $CCR6^+$ cells in CD, using the immunoperoxidase technique, original magnification x40. Neutrophilic staining is demonstrated.

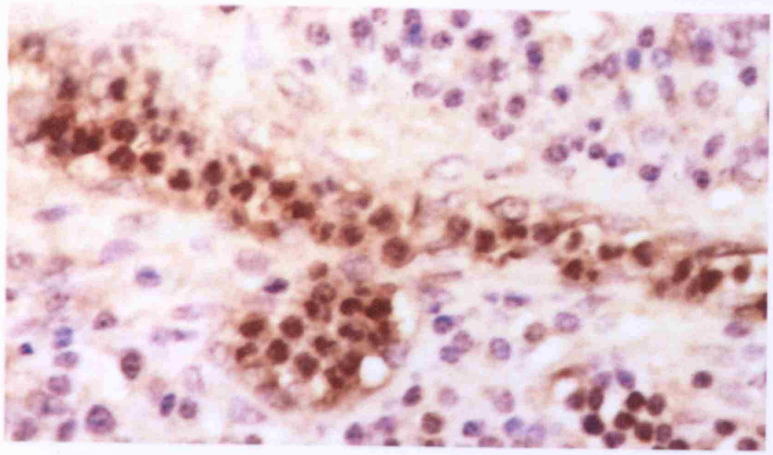
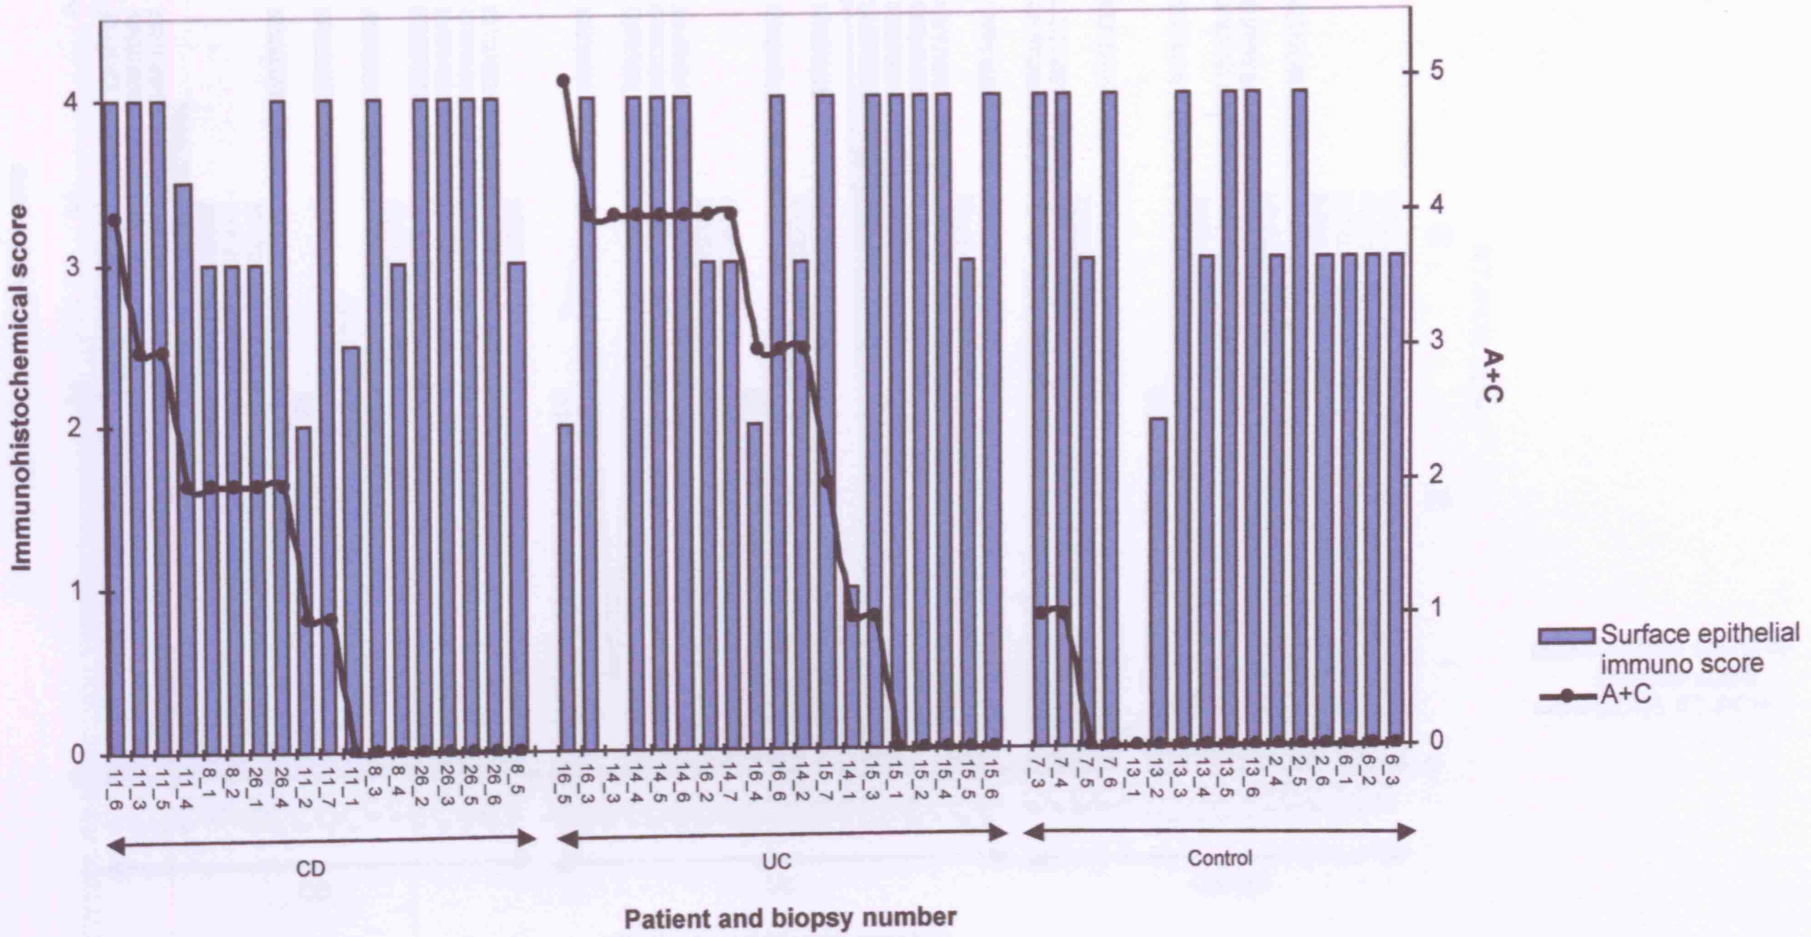
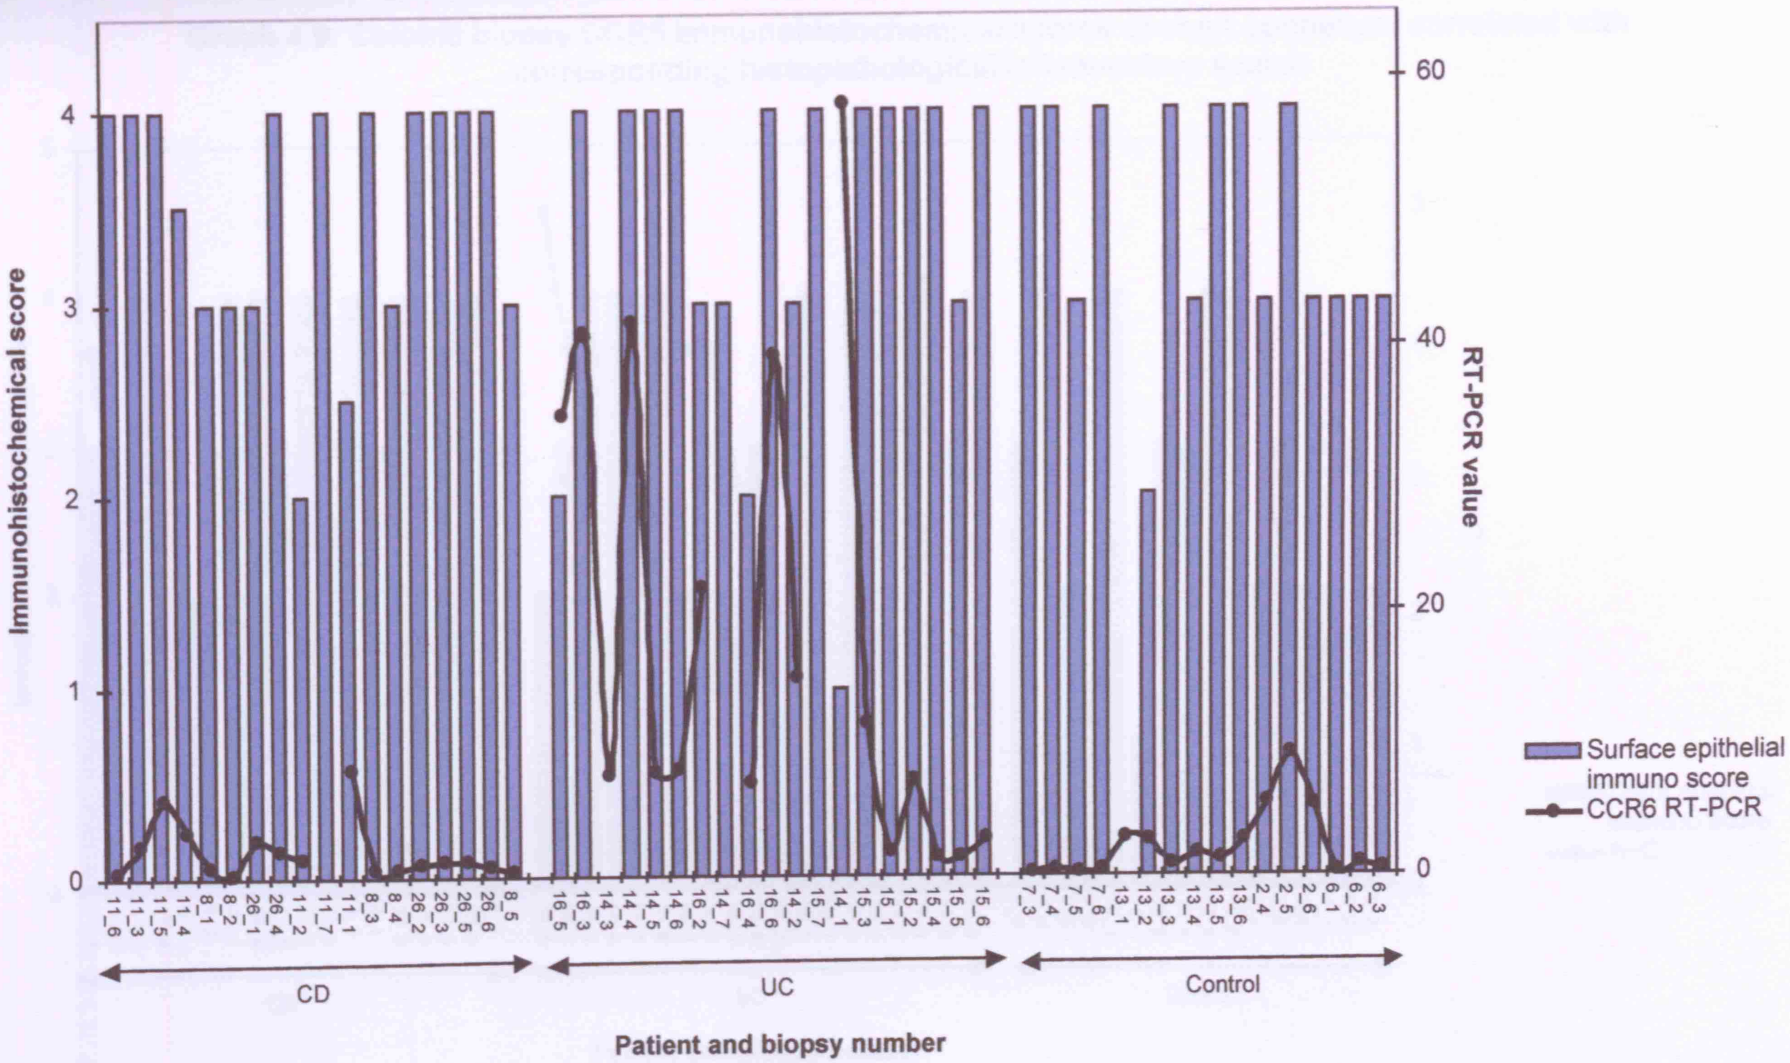


Graph 4.7: Colonic biopsy CCR6 immunohistochemical scores of surface epithelium correlated with corresponding histopathological inflammatory scores



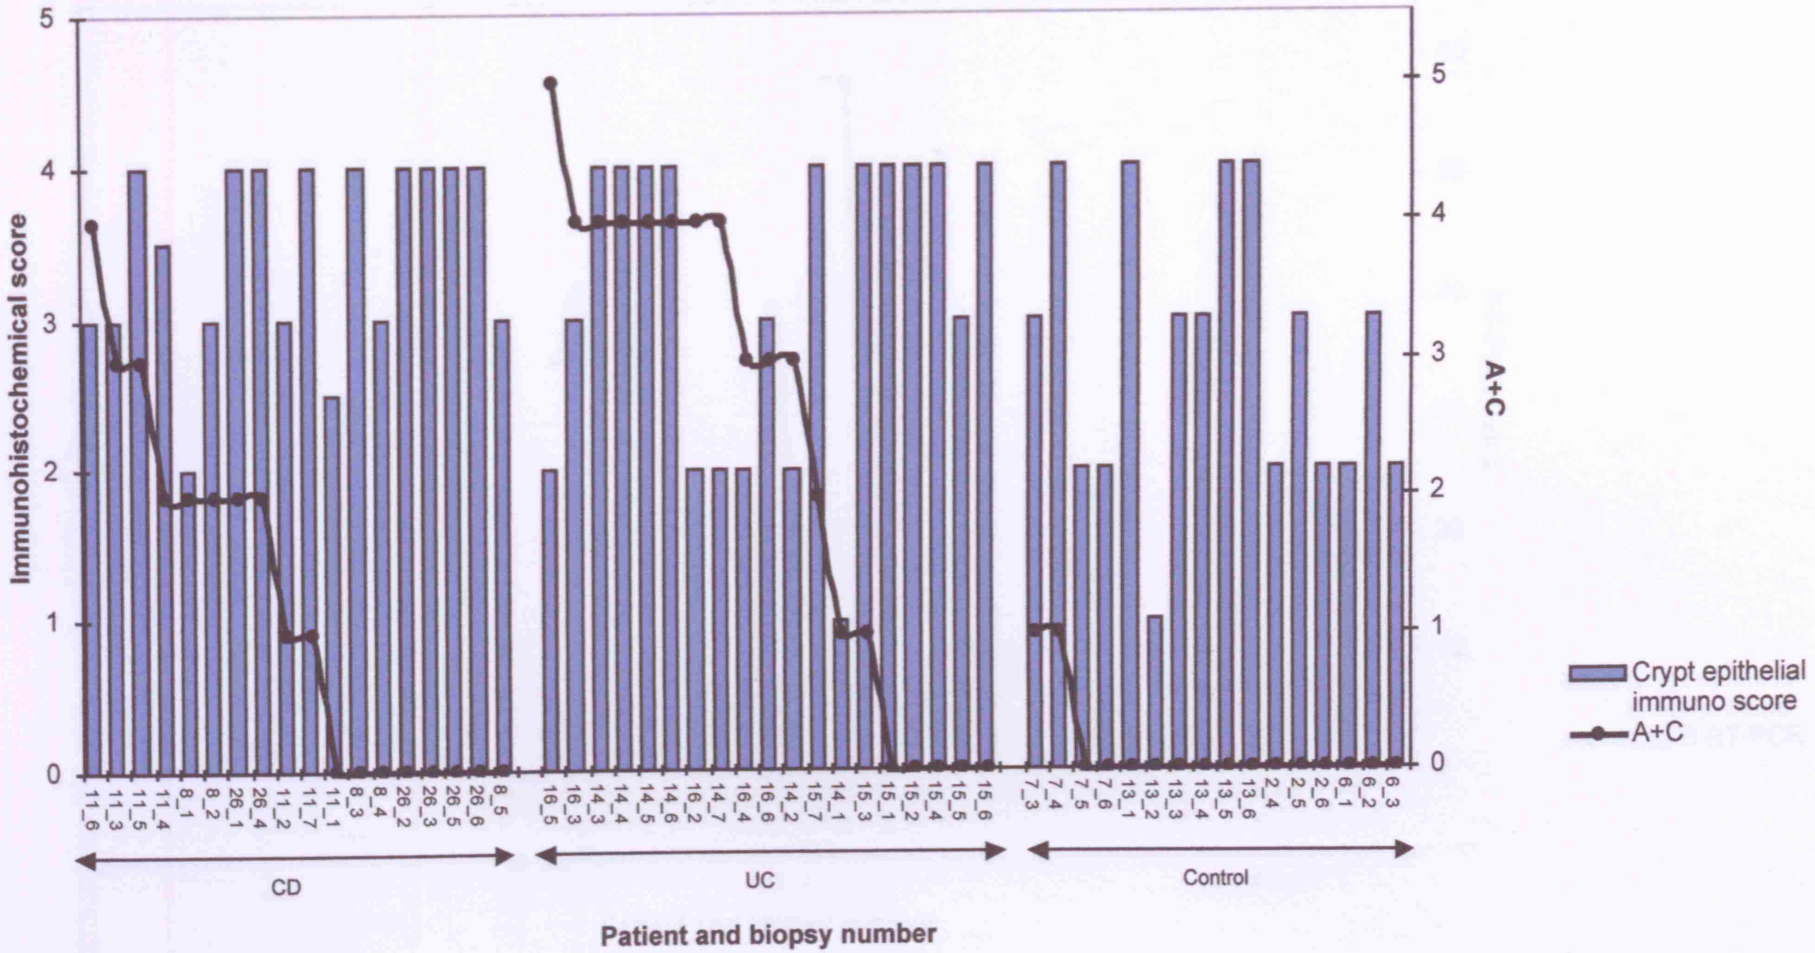
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C. Patient and sample details are outlined in appendix table 2.3, and immunohistochemical scores in table 3.8.

Graph 4.8: Colonic biopsy CCR6 immunohistochemical scores of surface epithelium correlated with corresponding RT- PCR taqman values



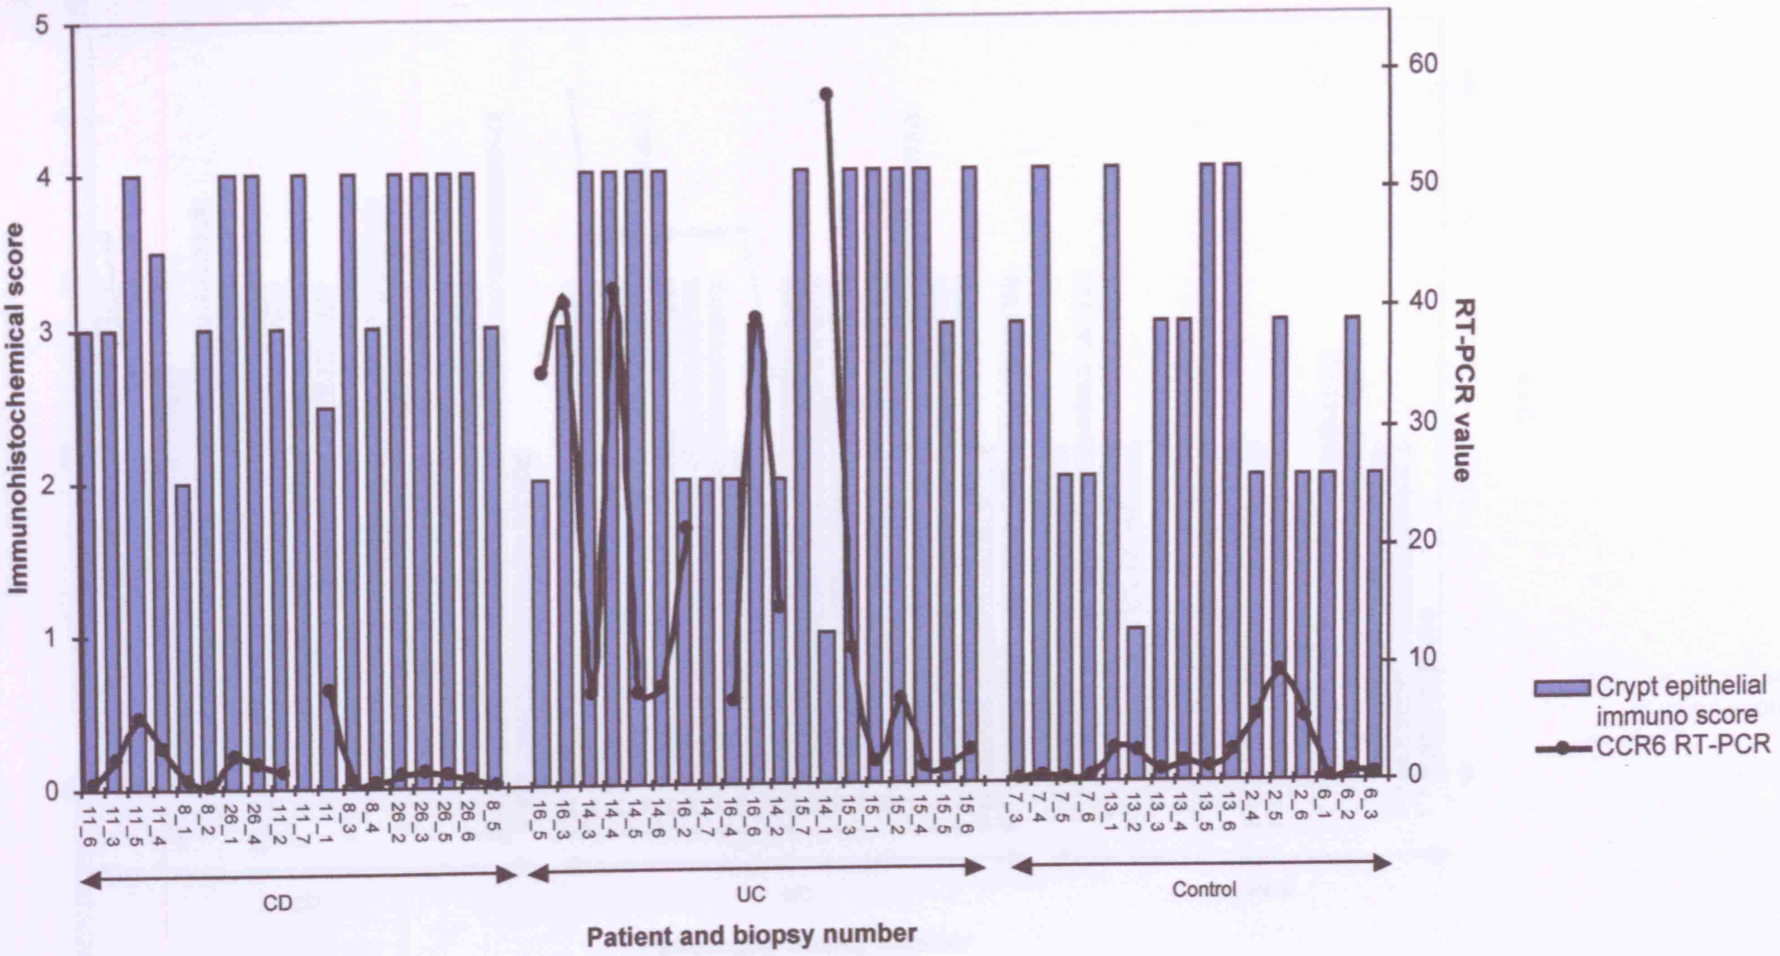
Patients are grouped according to disease. Patient and sample details are outlined in appendix table 2.3. Immunohistochemical scores are listed in table 4.5, and RT-PCR values in table 3.8.

Graph 4.9: Colonic biopsy CCR6 immunohistochemical scores of crypt epithelium correlated with corresponding histopathological inflammatory scores



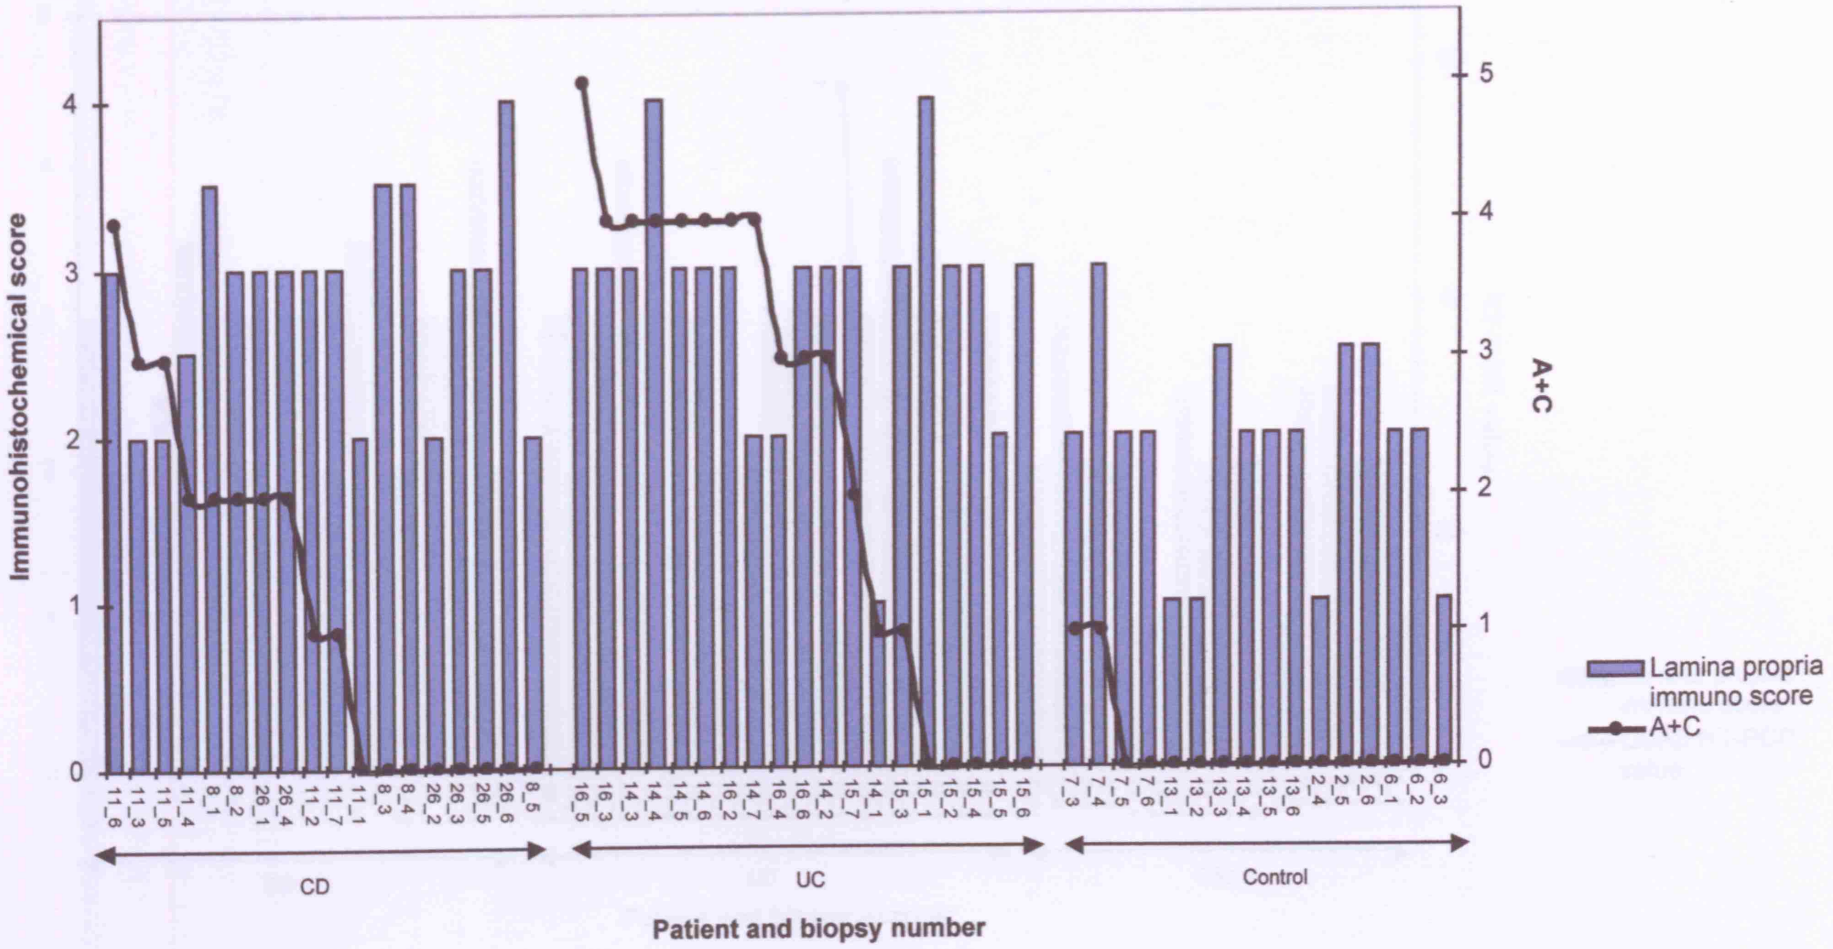
Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C. Patient and sample details are outlined in appendix table 2.3, and immunohistochemical scores in table 4.5.

Graph 4.10: Colonic biopsy CCR6 immunohistochemical scores of crypt epithelium correlated with corresponding RT-PCR taqman values



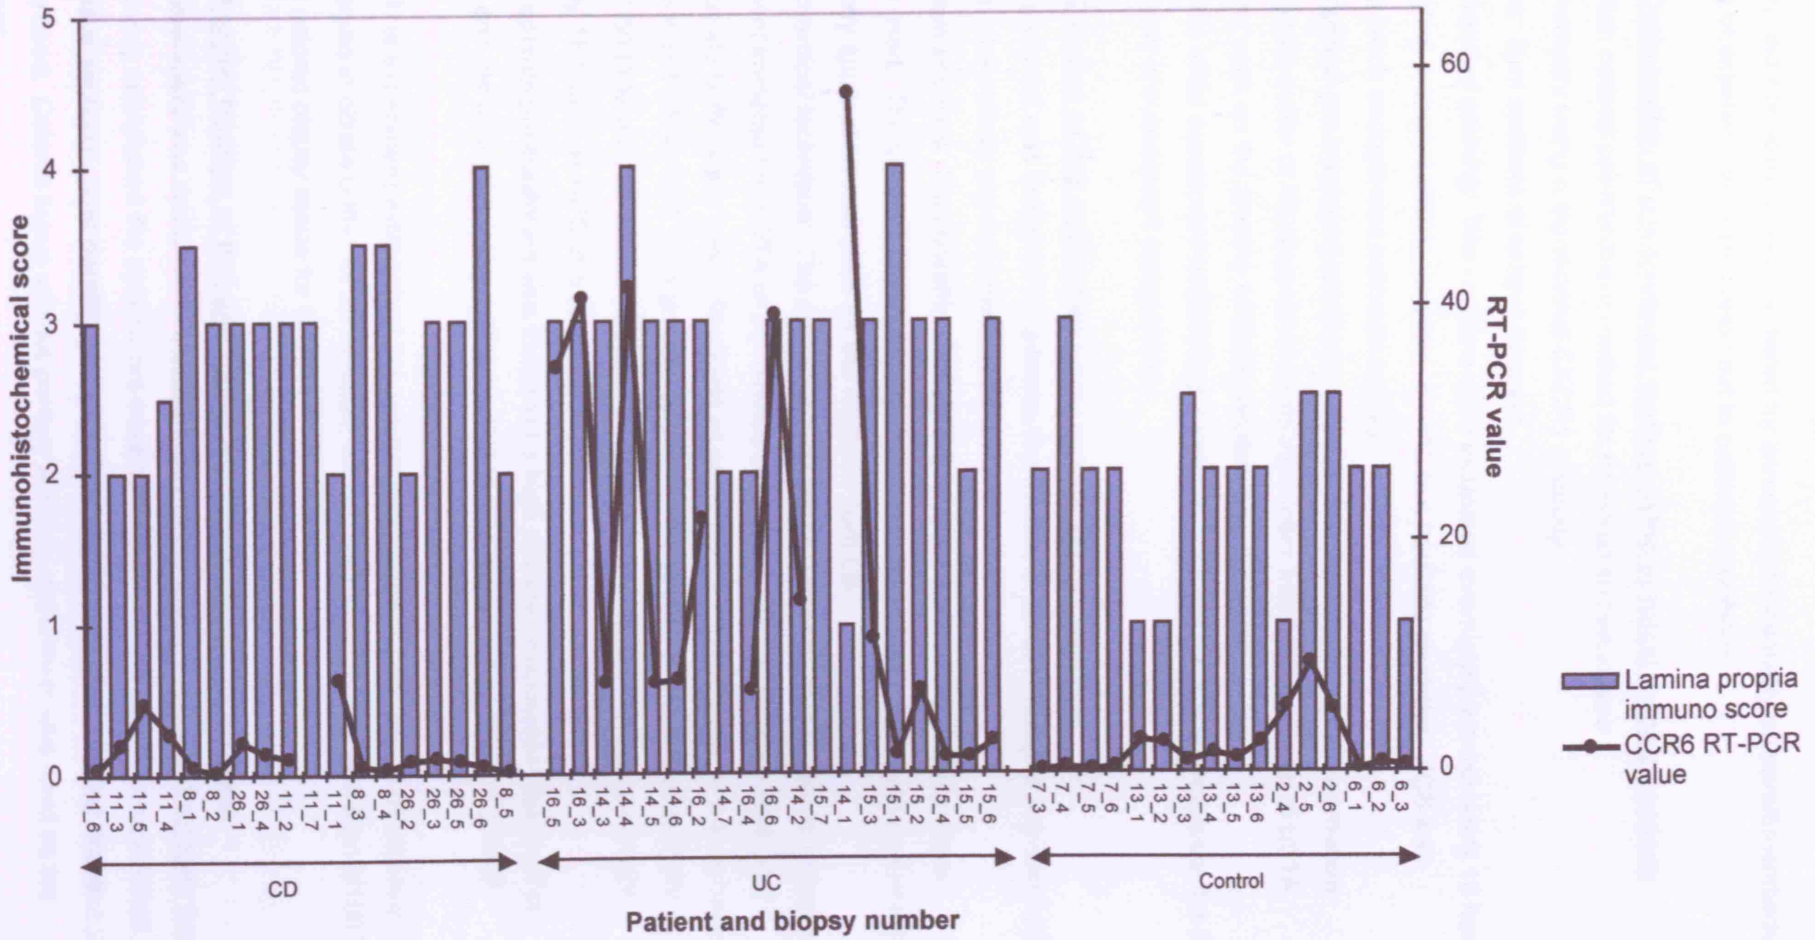
Patients are grouped according to disease. Patient and sample details are outlined in appendix table 2.3. Immunohistochemical scores are listed in table 4.5, and RT-PCR values in table 3.8.

Graph 4.11: Colonic biopsy CCR6 immunohistochemical scores of lamina propria correlated with corresponding histopathological inflammatory scores



Patients are grouped according to disease, and chronologically placed according to inflammatory scores A+C. Patient and sample details are outlined in appendix table 2.3, and immunohistochemical scores in table 3.8.

Graph 4.12: Colonic biopsy CCR6 immunohistochemical scores of lamina propria correlated with corresponding RT-PCR taqman values



Patients are grouped according to disease. Patient and sample details are outlined in appendix table 2.3. Immunohistochemical scores are listed in table 4.5, and RT-PCR values in table 3.8.

4.4 Immunohistochemical localisation of CXCR1 using the immunoperoxidase technique

As this antibody had not been previously tested for immunohistochemistry on paraffin-embedded tissue, a series of experiments were carried out to optimise conditions.

4.4.1 Optimisation of pre-treatment method using surgical colonic sections

Aim: To establish optimal pre-treatment method for horseradish peroxidase immunohistochemistry using a monoclonal CXCR1 antibody.

Tissue sections: 3μm sections of colonic biopsies.

Immunohistochemical staining: The sections were incubated overnight (approximately 18 hours) in a 1/50 (10μg/ml) primary antibody solution at +4°C in a humidity chamber. FCS was incorporated to block endogenous peroxide activity.

Results: The optimal pre-treatment conditions were 25 minutes high-powered microwave treatement in citrate buffer or 90 seconds of pressure-cooker treatmet immersed in EDTA. However, further work on the primary antibody dilution was necessary.

Conclusion: This initial experiment established 2 optimal pre-treatments preparations of the link conjugates for use in subsequent experiments.

4.4.2 Titration of link antibodies using colonic biopsy sections

Aims: This experiment was designed to optimise the dilution of CXCR1 receptor link antibodies, and to establish the optimal pre-treatment method.

Methods: Tissue sections: 3μm paraffin embedded, formalin-fixed colonic biopsy tissue sections were used. The sections were obtained from patients with UC. Colonic tissue without primary antibody application was used for the negative controls.

Immunohistochemical technique: The optimal pre-treatment methods of 90 seconds of pressure cooker treatment immersed in EDTA or 25 minutes of high powered-microwave treatment immersed in citrate buffer were used. Blockade of endogenous peroxide activity was achieved by a 5% solution of FCS in TBS. The primary antibody was applied at the following dilutions varying from 1/50 (10μg/ml) to 1/1000 (0.5μg/ml). The sections were incubated overnight (approximately 18 hours) at +4°C in a humidity chamber.

Results: The optimal pre-treatment was found to be high powered microwave-treatment in citrate buffer, and the optimal primary antibody dilution was found to be less than 1/1000 (0.5μg/ml).

Conclusion: This experiment established the optimal pre-treatment preparation of microwave cooking immersed in citrate buffer for 25 minutes, with an optimal dilution of less than 1/1000 (0.5μg/ml) for colonic biopsy tissue for CXCR1.

4.4.3 Further titration of link antibodies using colonic biopsy sections

Aims: This experiment was designed to establish the optimal dilution of CXCR1 receptor link antibodies, having established the optimal pre-treatment method in the previous experiment.

Methods: Tissue sections: 3μm paraffin embedded, formalin-fixed colonic biopsy tissue sections were used. Colonic tissue without primary antibody application was used as the negative control.

Immunohistochemical technique: The optimal pre-treatment technique of 25 minutes in citrate buffer in a microwave on high power was used. Blockade of endogenous peroxide activity, was achieved by of a 5% solution of FCS in TBS. The primary antibody was applied at dilutions varying from 1/1000 (0.5μg/ml) to 1/1400 (0.357μg/ml). The sections were incubated overnight (approximately 18 hours) at +4°C in a humidity chamber.

Results: The optimal primary antibody dilution was found to be 1/1400, corresponding to a protein concentration of 3.3μg/ml.

Conclusion: This experiment established the optimal dilution of CXCR1 antibodies for immunohistochemistry on colonic biopsies as 1/1400 (3.3μg/ml) with the use of FCS as a blocking agent, with high-powered microwave cooking immersed in citrate buffer for 25 minutes as the optimal pre-treatment method.

4.4.4 Immunohistochemical localisation and scoring of CXCR1 on colonic biopsies

Aims: Previous experiments had established the optimum conditions for staining of the CXCR1 chemokine on colonic biopsies. These include high-powered microwave cooking in citrate buffer for 25 minutes, with an antibody dilution of 1/1400 (0.357μg/ml), with a 5% FCS at the initial blocking step, primary antibody solutions, in addition to the secondary and tertiary dilutions. This technique was used on colonic biopsy series from 10 patients, obtained during colonoscopic examination.

Tissue sections: 3μm paraffin embedded, formalin-fixed colonic biopsy tissue sections used from the 10 patients: a total of 18 biopsies from 3 patients with UC, 18 biopsies from 3 patients with CD, 18 biopsies from 4 patients with no disease (control). Sections were used from control patients 2, 6, 7, 13; from UC patients 14, 15, 16; and from CD 8, 11, 26. In addition, 2 negative controls were included. Patient details are outlined in appendix table 2.3.

Immunohistochemical technique: The optimal pre-treatment method of high-powered microwave cooking was used. Blockade of endogenous peroxide activity was achieved by incubation in a 5% FCS. Sections were incubated overnight (18 hours approximately) at +4 °C in the primary anti-CCR6 antibody, in a humidity chamber at a dilution of 1/1400 (0.357μg/ml).

Scoring: A semi-quantitative score from 0 (none) to 4 (dense confluent staining) was determined for epithelium, and percentage immunoreactive lamina propria cells determined. The scoring was performed under blind conditions, whereby the slide identity was concealed, and all the slides were allocated a number randomly. Unblinding only took place when all the scoring was complete. In some slides, the blood vessels could not be identified clearly, so this score was omitted where necessary. The immunohistochemical scores are detailed in table 4.8. Once scoring reliability had been ensured statistically, the original scores were correlated with both microarray data and histopathology inflammation scores. For each biopsy, a corresponding biopsy from the same area had been assessed by a consultant histopathologist, and scored on the basis of inflammation as detailed in appendix table 1.

Table 4.8: CXCR1 immunohistochemistry semi-quantitative assessment scores for the colonic biopsy series, with histopathological inflammatory scores, CXCR1 gene array expression levels and CXCL1 taqman real-time quantitative RT-PCR values.

Mean	3.1759	3.1389	0.037
Sum_sq	564.75	553.25	5
SS	20.0787	21.2083	4.9259
Variance	0.3788	0.4002	0.0929
Standard Deviation	0.6155	0.6326	0.3049

$Mean_A - Mean_B = 0.037$

$t = 0.89$

$df = 53$

Two-tailed $p = 0.376504$

On the basis of this $p>0.05$, the null hypothesis cannot be rejected, i.e. there is no statistical difference between the original and repeat scoring values. The scoring reducibility is therefore not un-acceptable statistically.

Results: Where the primary antibody incubation had been omitted, there was no staining (figure 4.3a). CXCR1 immunoreactivity is seen to be widespread, on a number of cell types, including plasma cells, macrophages, dendritic cells, neutrophils, goblet cells, myofibroblasts. The normal controls showed no epithelial immunoreactivity (figures 4.3b). The $CXCR1^+$ lamina propria cell population was distributed differently to CCL20 and CCR6, with little staining of subepithelial cells in controls, but there was clear staining of small round cells within the deeper lamina propria (figures 4.3b). Both CD and UC specimens showed an upward extension of $CXCR1^+$ cells (figure 4.3c-f). There was strong vascular endothelial staining.

Non-parametric correlation analyses between CXCR1 immunohistochemical scores and corresponding RT-PCR values indicated no association. Spearman's correlation coefficients were as follows: 0.30 (p=0.034) for lamina propria, 0.14 (p=0.36) for surface epithelium, 0.067 (p=65) for crypt epithelium and 0.035 (p=0.83) for vascular endothelium.

Figure 4.3a, b: Colonic immunohistochemical staining of $CXCR1^+$ cells using the immunoperoxidase technique. Original magnification x10 (a), x40 (b). A negative control is demonstrated in (a). Control tissue staining is demonstrated in (b).

4.5 Immunohistochemical localisation of CXCR2 using immunoperoxidase technique

As this antibody had not been previously tested for immunohistochemistry on paraffin-embedded tissue, a series of experiments were carried out to optimise conditions.

4.5.1 Optimisation of pre-treatment method using surgically-obtained colonic and appendix sections

Aim: To establish optimal pre-treatment method for horseradish peroxidase immunohistochemistry using a monoclonal CXCR2 antibody.

Preparation of section: 3μm sections of colonic biopsy and surgically-obtained appendix tissue were used. Colonic and appendix tissue without primary antibody application were used as negative controls.

Immunohistochemical technique: Blockade of endogenous peroxide activity was achieved by incubation in 1% NHS. The sections were incubated overnight (approximately 18 hours) at +4°C in a humidity chamber in antibody dilutions varying from 1/50 (10μg/ml) to 1/100 (5μg/ml).

Results: There were 2 pre-treatment conditions that led to higher quality staining; 90 seconds of pressure cooker treatment immersed in EDTA, and 25 minutes of high powered-microwave treatment in citrate buffer. However, although these 2 conditions were definably better, the slides were over stained. There was considerable background staining, including on the control negative slide. The company had recommended 1/25 dilution (20μg/ml), and this was found to be too strong for appendix tissue.

Conclusion: This initial experiment established 2 optimal pre-treatment preparations of the link conjugates for use in subsequent experiments.

4.5.2 Titration of primary antibody on colonic biopsy sections

Aims: The aim of this experiment was to optimise the dilution of CXCR2 link antibodies using the 2 optimal pre-treatment methods.

Methods: Tissue sections: 3μm paraffin-embedded, formalin-fixed colonic biopsy tissue sections were used. Colonic tissue without primary antibody application was used as the negative control.

Immunohistochemical technique: The optimal pre-treatment methods of 90 seconds of pressure cooker treatment immersed in EDTA or 25 minutes of high-powered microwave treatment in citrate buffer were used. Blockade of endogenous peroxide activity was achieved by a 5% solution of FCS in TBS. The primary antibody dilutions used varied from 1/80 (6.25μg/ml) to 1/175 (2.86μg/ml). The sections were incubated overnight (approximately 18 hours) at +4°C in a humidity chamber.

Results: The optimal dilution was found to be 1/150 (0.36μg/ml), with high-powered microwave treatment in citrate buffer for 25 minutes.

Conclusion: This experiment established the optimal pre-treatment preparation of microwave cooking immersed in citrate buffer for 25 minutes, with an optimal dilution of 1/150 (3.33μg/ml) CXCR2 for colonic biopsy tissue.

4.5.3 Immunohistochemical localisation and scoring of CXCR2 on colonic biopsies

Aims: Previous experiments had established the optimum conditions for staining of the CXCR2 chemokine receptor on colonic biopsies. These include high-powered microwave cooking in citrate buffer for 25 minutes, with an antibody dilution of 1/150, with a 5% FCS at the initial blocking step, primary antibody solutions, in addition to the secondary and tertiary dilutions. This technique was used on colonic biopsy series from 10 patients, obtained during colonscopic examination.

Tissue sections: 3μm paraffin embedded, formalin-fixed colonic biopsy tissue sections used from the 10 patients: a total of 18 biopsies from 3 patients with UC, 18 biopsies from 3 patients with CD, 18 biopsies from 4 patients with no disease (control). In addition, 2 negative controls were included. The subset was chosen on the basis of the previous microarray data. Sections were used from control patients 2, 6, 7,13; from UC patients 14, 15, 16; and from CD patients 8, 11, 26. Patient details are outlined in appendix table 2.3.

Immunohistochemical technique: The optimal pre-treatment method of high-powered microwave cooking was used. Blockade of endogenous peroxide activity was achieved by incubation in a 5% FCS. Sections were incubated overnight (18 hours approximately) at +4 °C in the primary anti-CXCR2 antibody, in a humidity chamber, at a dilution of 1/150 (3.33μg/ml).

Scoring: A semi-quantitative score from 0 (none) to 4 (dense confluent staining) was determined for epithelium, and percentage immunoreactive lamina propria cells determined. The scoring was performed under blind conditions, whereby the slide identity was concealed, and all the slides were allocated a number randomly. Unblinding only took place when all the scoring was complete. In some slides, the blood vessels could not be identified clearly, so this score was omitted where necessary. The scores are listed in table 4.11.

Table 4.11: CXCR2 immunohistochemistry semi-quantitative assessment scores for the colonic biopsy series, with histopathological inflammatory scores, CXCR2 gene expression levels and CXCR2 TaqMan real-time quantitative RT-PCR values.

Statistical validation: As the scoring was semi-quantitative, it was important to statistically validate the scoring technique consistency and reliability. 11 slides were re-scored for all parameters, blind from the slide identity and the original score. Each value was paired with the initial scoring value. These pairs were incorporated into a student's t-test for paired parametric data. Each of the first scores for 11 slides was paired with the corresponding second scores, as listed in table 4.12. This statistical test is useful for investigating a variable in two groups where there is a meaningful one-to-one correspondence between the data points in one group and

those in the other. The null hypothesis states that there is no significant difference between the 2 groups.

Table 4.13: Statistical validation table of CXCR2 semi-quantitative immunohistochemistry scores.

Values	X_a	X_b	$X_a - X_b$
n	56	56	56
Sum	140	142	-2
Mean	2.5	2.5357	-0.0357
Sum_sq	386.5	397	3.5
SS	36.5	36.9286	3.4286
Variance	0.6636	0.6714	0.0623
Standard Deviation	0.8146	0.8194	0.2497

$Mean_A - Mean_B = -0.0357$

$t = -1.07$

$df = 55$

Two-tailed $p = 0.1446445$

On the basis of this $p>0.05$, the null hypothesis cannot be rejected, i.e. that there is no statistical difference between the original and repeat scoring values. The scoring reducibility is therefore not unacceptable statistically.

Results: Where the primary antibody incubation had been omitted, there was no staining (figure 4.4a). The density of $CXCR2^+$ cells were higher, with >75% of cells $CXCR2^+$ in 2/17 controls, 10/17 UC and 10/15 CD specimens. Patchy immunoreactivity is seen on surface epithelium in all groups, with no overall increase in IBD (figures 4.4b-d, g, i). The lamina propria infiltrate is denser in both CD and UC specimens, with most cells $CXCR2^+$ in the upper lamina propria (4.4c, d, g). Purulent exudate is almost totally $CXCR2^+$(figure 4.4f).

Non-parametric correlation analyses between CXCR2 immunohistochemical scores and corresponding RT-PCR values indicated no association. Spearman's correlation coefficients were as follows: 0.19 (p=0.20) for lamina propria, -0.22 (p=0.13) for surface epithelium, -0.11 (p=0.44) for crypt epithelium and 0.01 (p=0.95) for vascular endothelium.

4.6 Discussion

There was generally good correlation between immunohistochemical scores for CCL20, CCR6, CXCR1 and CXCR2 with mRNA expression. Of 17 normal control biopsies, 2 showed enhanced expression of CCL20 in crypt epithelium (score >2), compared to 11/16 UC and 6/15 CD specimens. Similar increase was seen in CCL20 expression in surface epithelium (1/17 control biopsies, 10/16 UC and 6/15 CD). CCL20-positive ($CCL20^+$) lamina propria cell density exceeded 50% of total cells in 2/17 controls, 12/16 UC and 12/15 CD specimens. $CCR6^+$ cells were particularly increased in the deep lamina propria, with >50% of total cells $CCR6^+$ in 1/17 controls, 13/16 UC and 12/15 CD specimens, while the density of $CXCR1^+$ and $CXCR2^+$ cells were higher, with >75% of cells $CXCR2^+$ in 2/17 controls, 10/17 UC and 10/15 CD specimens.

The increased surface and crypt epithelial expression of CCL20 in IBD tissue is consistent with its function in mucosal immunity, where it induces the local migration of dendritic cell subsets and lymphocyte subsets expressing its receptor CCR6, including B cells and memory T cells expressing gut-homing ($\alpha4\beta7$) and skin homing (CLA) Integrins (Liao et al, 1999), (Nakayama et al, 2001). This correlates well with results from other centres. For example, Dieu-Nosjean et al demonstrated that CCL20 is a major chemokine produced by activated epithelial cells, and selectively active on Langerhan cells and their precursors. This implicates CCL20 to be a pivotal chemokine in the control of Langerhan cell recruitment at inflamed epithelial surfaces and in the regulation of epithelial immunity (Dieu-Nosjean et al, 2000). *In situ* hybridisation has revealed that epithelial cells of intestinal tissues express CCL20, especially those lining lymphoid follicles. It has also been shown that CCL20 is chemotactic for memory T-cells and naïve B cells in Peyer's patches. Thus, this chemokine may well be physiologically involved in formation and function of the mucosal lymphoid tissues by attracting lymphocytes and dendritic cells toward epithelial cells (Tanaka et al. 1999).

The neutrophilic staining for CCL20 correlates well with a study by Scapini, which demonstrated that neutrophils produce CCL20 when cultured with either LPS or TNF-α (Scapini et al, 2001).

There was a moderate correlation between CCR6 mRNA expression and immunohistochemical receptor staining within the epithelium, although this association was weak for the lamina propria and vascular endothelium. Qualitatively, an increased expression in the lamina propria, occasional dendritic cell, vascular endothelium, lymphocyte subsets and crypt epithelium in IBD cases was observed. In addition, neutrophils exhibited staining, indicating these cells are likely to be involved in recruitment of lymphocytes and dendritic cells. Lymphoid staining primarily corresponded to T-areas.

CCR6 is required for the localisation of immature dendritic cells to the sub-epithelial zone. It is chemotactic to lymphocytes and dendritic cells, and is a mucosa-specific regulator of humoral immunity in the intestinal mucosa (Cook et al, 2000). The presence or absence of $CCR6^+$ cells does not implicate nor refute ongoing immunological activation, as the expression of CCR6 is down regulated following CCL20 binding to dendritic cells. CCR7 is then up regulated, facilitating dendritic migration to lymph nodes in response to a CCL19/21 chemokine gradient.

There was a predominance of $CCR6^+$ cells within the deeper lamina propria in IBD cases. Although it is difficult to be sure of the immunological significance, this pattern may well be part of CCR6 down regulation following dendritic cell activation.

There was weak correlation between mRNA expression and immunohistochemical staining for CXCR1. Specific interpretation of the staining was made difficult by widespread staining in a variety of cell types, as previously noted (Williams et al, 2000). CXCR1 immunoreactivity was noted on a variety of cell types including plasma cells, macrophages, dendritic cells, neutrophils, goblet cells and myofibroblasts within the lamina propria. There was also strong vascular endothelial immunoreactivity. $CXCR1^+$cells were broadly absent from the subepithelial cells in control tissue, with a clear staining within the deeper lamina propria. There was an upward extension in IBD, with $CXCR1^+$ cells prominent throughout the lamina propria including in the subepithelial area.

CXCR1 was seen to be up regulated in a sub-population of macrophages deep to the epithelium in UC, confirming William's et al paper, who also noted an up regulation of B and T cells outside the germinal centre areas in UC. However, they also noted a similar pattern in acute appendicitis, indicating that this may be not specific to IBD. Finally, this group demonstrated an intense up regulation of CXCR1 by the luminal epithelium in UC but not in acute appendicitis, so this may be specific to IBD.

There was moderate association between CXCR2 RT-PCR values and the epithelial immunohistochemical scores for corresponding biopsies although the association within the lamina propria and vascular endothelium was weak. There was patchy immunoreactivity on surface epithelium in all groups with no overall increase in IBD. Purulent exudate was almost totally $CXCR2^+$. The pattern of immunohistochemical staining for CXCR2 differed from that demonstrated in William's et al paper, with more widespread lamina propria staining in IBD tissue, particularly in the upper lamina propria. This CXCL8 receptor may have a role in mediating the immune response in the gastrointestinal tract. Further characterisation is necessary.

5.6 Discussion

5.1 Introduction

From the microarray data, a specific subset of chemokines was up regulated in inflamed IBD colon, consisting of CXCL's1-3, CXCL8 and CCL20. To characterise epithelial cell chemokine production further, *in vitro* study was undertaken using immortalised epithelial cell lines. The effect of pro-inflammatory stimulation on epithelial chemokine expression was assessed. A consistent pattern of chemokine production by Caco-2 and HT29 cells would provide further evidence for an epithelial cell chemokine response. The method of cell culture used is described in 2.2.5. Two cell lines were included to ensure the results were not merely anomalous to one cell line.

The human epithelial colon carcinoma cell lines Caco-2 and HT29 cells were chosen for studying expression of chemokines and cytokines, due to the spontaneous differentiation exhibited. In the pre-confluent state these cells are relatively undifferentiated. Several days post-confluency, these cells develop markers of a differentiated phenotype for absorptive enterocytes including the expression of digestive enzymes, tight junctions, a well developed brush-border, and a polarised morphology. For this reason, they were harvested at 48 hours post confluency, when they express a predominantly colonic phenotype so as to simulate in-vivo conditions as closely as possible, and allow correlation of data with those obtained from colonic biopsies (Engle et al 1998), (Ashburner et al, 2001). Study of Caco-2 cell lines is of particular relevance as they exhibit a similar pattern of inflammatory responsiveness to isolated colonocytes, more so than other colon cancer cell lines. Finally, primary epithelial cell culture was attempted using surgically obtained epithelial cells, to give a closer approximation to *in vivo* conditions.

Fujiie et al (2001) previously demonstrated human colon carcinoma cell lines express CCL20, up regulated by either TNF-α or IL-1β depending on lineage. In order to determine whether IL-1β and TNF-α were also capable of inducing human colon carcinoma cell lines to express the other chemokines identified as coordinately up regulated in inflamed IBD colon (CXCL's1-3 and CXCL8), the human chemokine array was used to profile gene expression of Caco-2 and HT-29 cells cultured with and without IL-1β, TNF-α, LPS, or IL-1β and TNF-α together. In order to investigate potential regulatory pathways previously implicated in epithelial CXC chemokine production, Caco-2 IL-1β and TNF-α dual stimulations were also performed in the presence of Trichostatin A (TSA) and benzamide to determine any involvement of histone deacetylation and poly (ADP-ribose) polymerase (PARP1) respectively (Wood et al, 1995), (Fusunyan et al, 1999), (Kawai et al, 2001), (Nirodi et al, 2001).

Many regulatory pathways, such as the transactivation of NF-κB have been implicated in epithelial CXC chemokine production (Wood et al, 1995), (Fusunyan et al, 1999), (Ashburner et al, 2001).

Validation of the measured chemokine response was undertaken at the protein level using ELISA on the supernatants collected from the stimulated Caco-2 cell culture plates at 2, 4 and

18 hours. These had been stored frozen at -70°C, and thawed at room temperature. The method used is described in 2.2.6.

5.2 Coordinate chemokine response in stimulated Caco-2 cells

5.2.1 Caco-2 cell count and viability assessment

Cell counts for passage number 4:

Live cell counts: 171, 203, 175, 185, 167, 158 (i.e. viable cells / standard grid sub-division)

Total live cell count in 6 grids = 1065, average = 176.5

Dead cell counts: 2, 0, 1, 2, 1, 0

Total dead cell counts in 6 grids = 6, average = 1

Number of live cells / total number cells x 100 = 99.44% viability

The cell count per volume was calculated using the following equation:

Total number of live cells x 10^4 x 2 (dilution factor) / ml = 3.53 x 10^6 cells/ml

In order to have 1.5 x 10^6 cells, 425 µl was added to 20 x 10cm petri dishes containing 10ml medium.

Cell counts for passage number 22:

Live cell counts: 94, 104, 112, 88, 138, 97, 88

Total live cell count in 6 grids = 633, average = 105.5

Dead cell counts: 4, 3, 6, 2, 4, 5

Total dead cell counts in 6 grids = 24, average = 4

Number of live cells / total number cells x 100= 96.35% viability

The cell count per volume was calculated using the following equation:

Total number of live cells x 10^4 x 2 (dilution factor) / ml = 2.11 x 10^6 cells/ml

In order to have 1.5 x 10^6 cells, 710.9µl were added to 30 x 10cm Petri dishes containing 10ml medium.

Cell counts for passage number 24:

Live cell counts: 203, 172, 202, 180, 149, 145

Total live cell count in 6 grids = 1051, average = 175.1666

Dead cell counts: 2, 3, 4, 1, 3, 6

Total dead cell counts in 6 grids = 19, average = 3.1666

Number of live cells / total number cells x 100 = 98.22% viability

The cell count per volume was calculated using the following equation:

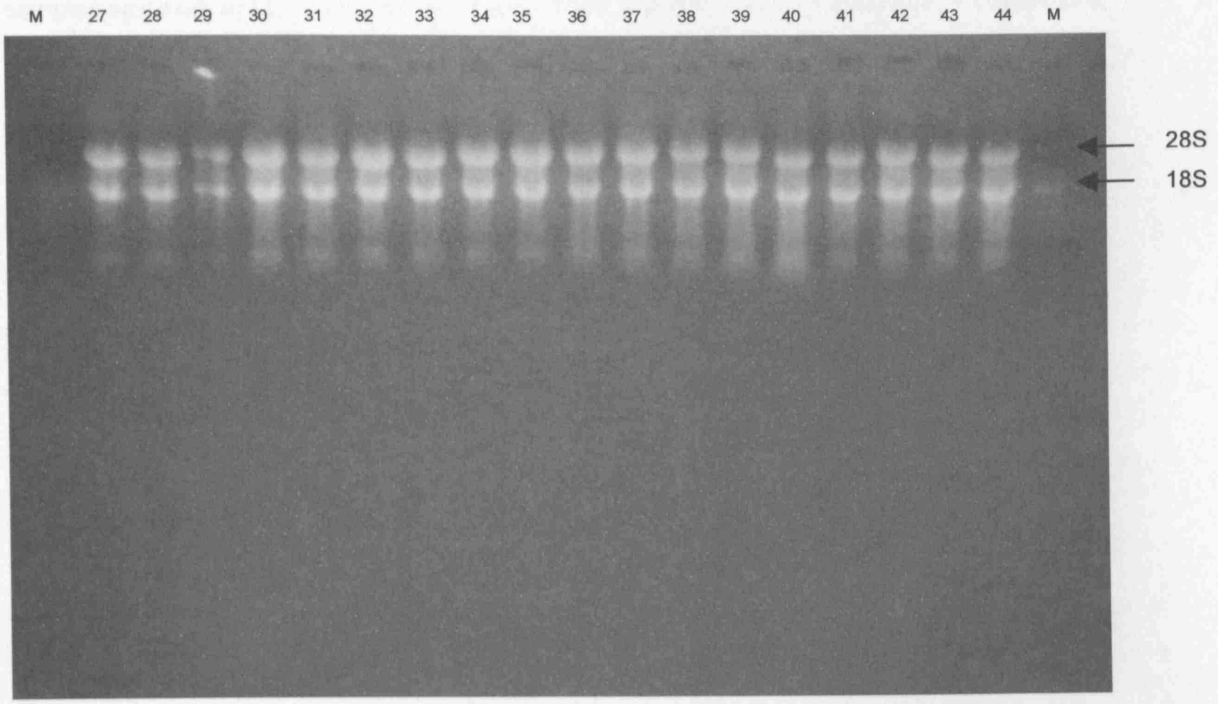
Total number of live cells x 10^4 x 2 (dilution factor) /ml = 3.503 x 10^6 cells/ml

In order to have 1.5 x 10^6 cells, 428.20µl was added to 20 x 10cm petri dishes containing 10ml medium.

5.2.2 RNA gel electrophoresis

The 18 and 28S ribosomal bands were clearly visible (figure 5.1).

Figure 5.1: Agarose gel electrophoresis for RNA extracted from Caco-2 cells. RNA was extracted from Caco-2 cells from passage numbers 4. This was loaded into an agarose gel, and run at 110V for 30 minutes. The 18 and 28S ribosomal bands are indicated.



5.2.3 Microarray results

The Microarray hybridised with cDNA probes derived from Caco-2 cells are represented in figure 5.2. with arrows demonstrating the spots for CCL20 pre- and post-stimulation with combinations of IL-1β, TNF-α, and LPS. Chromographic representation of hierarchical gene clustering is demonstrated in figure 5.3. The semi-quantitative results from the Caco-2 hierarchical clustering data are listed in table 5.1 and 5.2. As the chemokines were up regulated at 2 hours, the 4-hour samples were not analysed to conserve the limited number of arrays available. Furthermore, passage number 22 was not analysed.

Graphs 5.1-5.4 demonstrate the relative expression levels of selected chemokines by Caco-2 cells following 2 and 18 hours exposure to various stimuli, as measured by microarray analysis. Minimal expression was detected at 18 hours post-stimulation.

Figure 5.2: Hybridised genes for Caco-2 analysis, detected by radio labelling, with arrows demonstrating the spots corresponding to CCL20 pre- and post-stimulation with combinations of IL-1β, TNF-α and LPS.

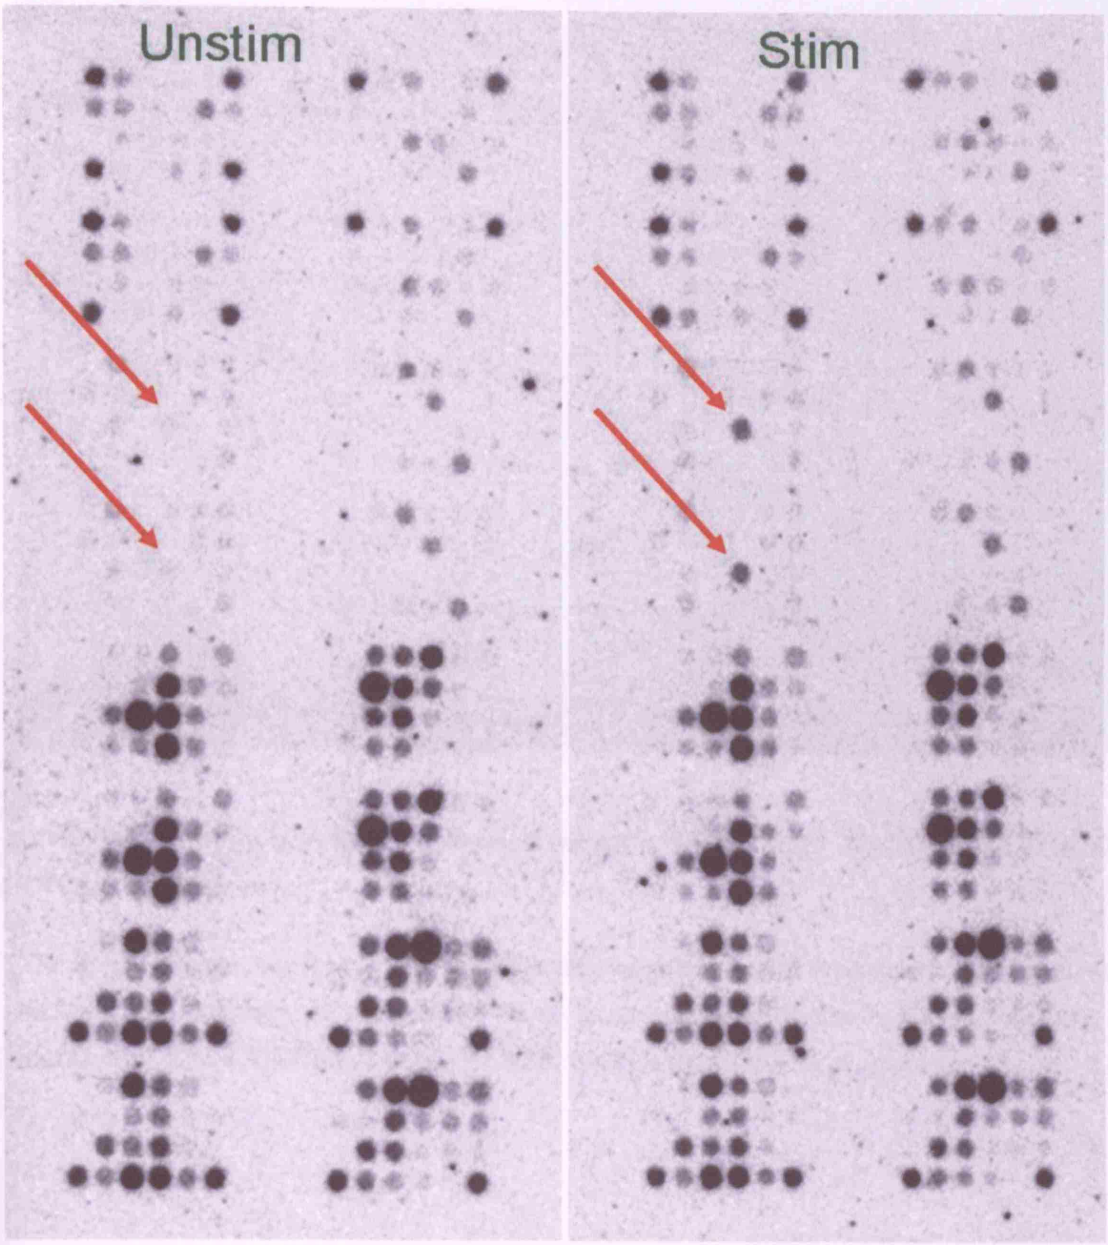


Figure 5.3: Hierarchical cluster of Caco-2 expression data at 2 hours

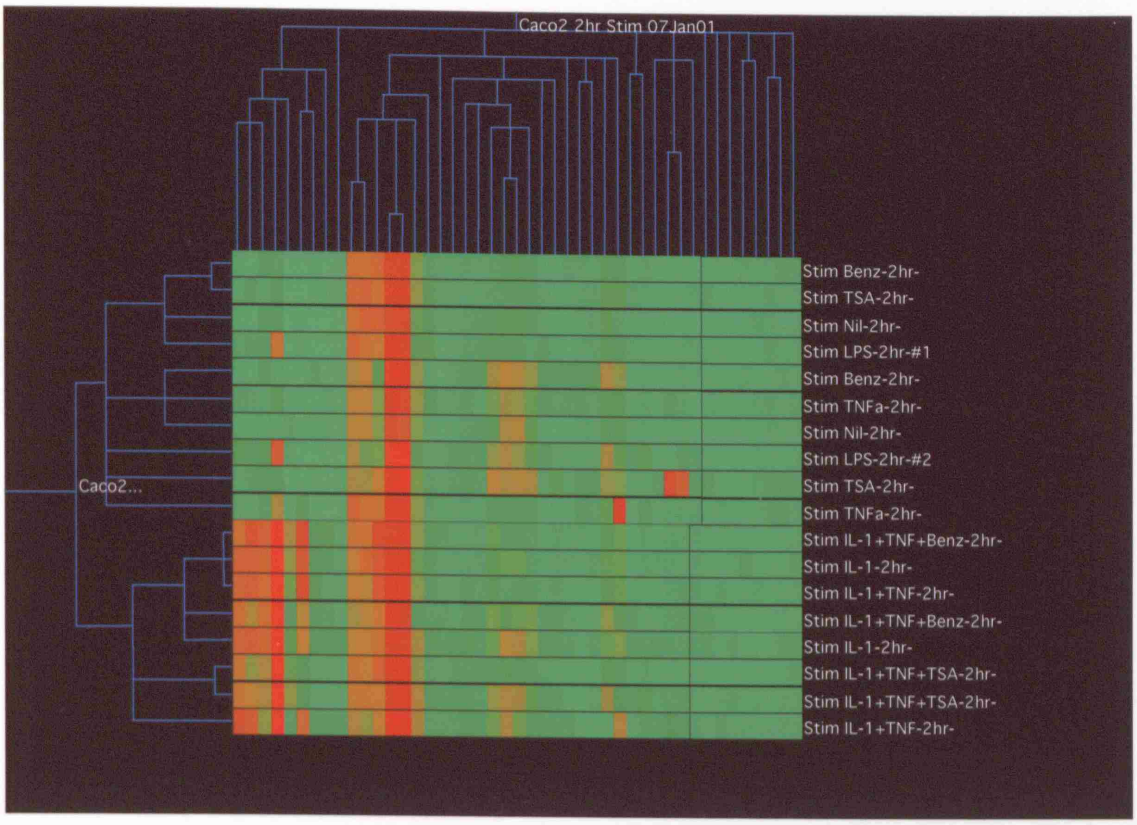

Chemokines are represented in columns from left to right: CXCL1, CXCL3, CXCL2, CCL20, CXCL8, CXCL10 etc.

The levels of gene expression are colour-coded whereby green represents a low level, and red represents a high level of expression. All IL-1β-stimulated cells cluster together due to increased CXCL1, CXCL3, CXCL2, CCL20, CXCL8 and CXCL10 expression.

Table 5.1: 2-hour normalised chemokine expression levels of CXCL1, 2, 3, 8, 10, CCL20 and actin from microarray analysis for Caco-2 cells stimulated with nil/IL-1β/ TNF-α/IL-1β + TNF-α/IL-1β +TSA/IL-1β + TNF-α + benzamide/TSA/LPS.

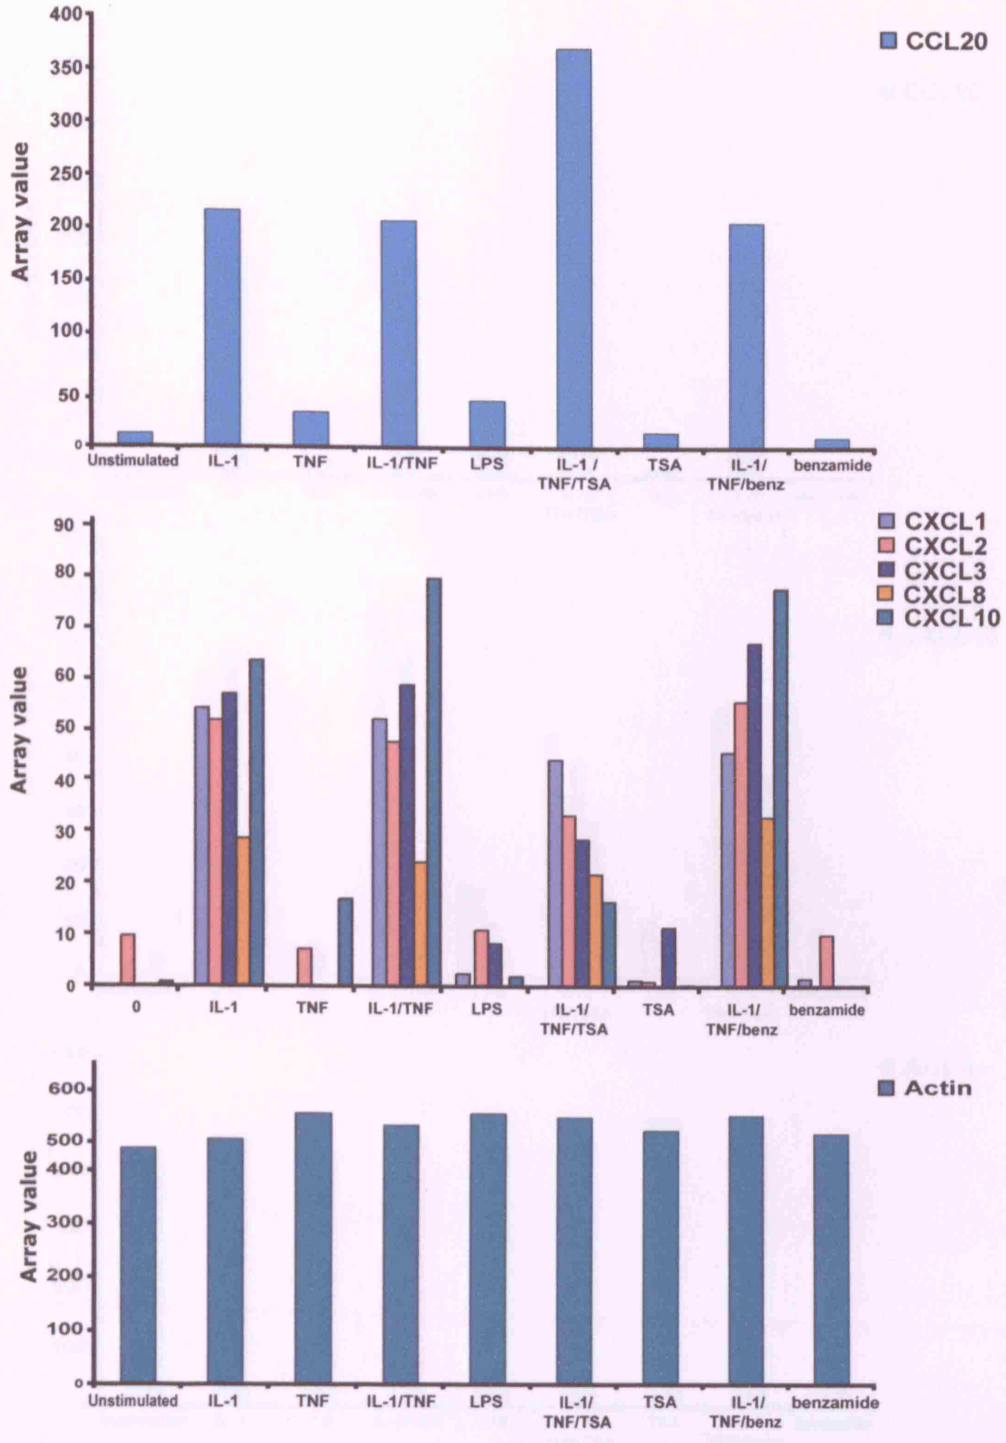
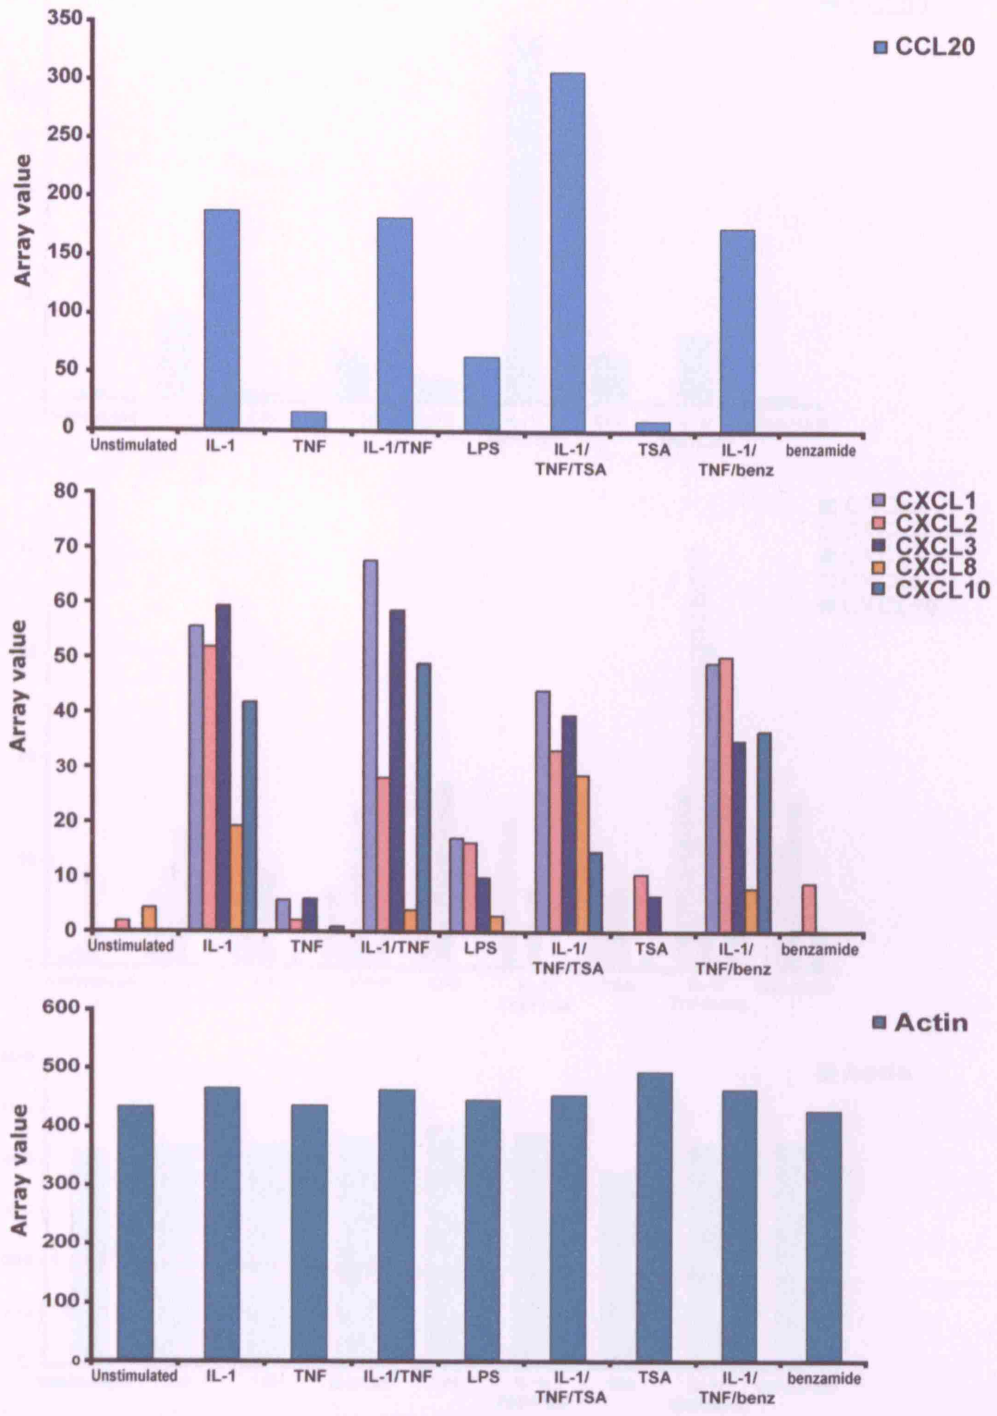
Graph 5.1: 2-hour chemokine expression levels from microarray analysis of Caco-2 cells post pro-inflammatory stimulation (passage 4).



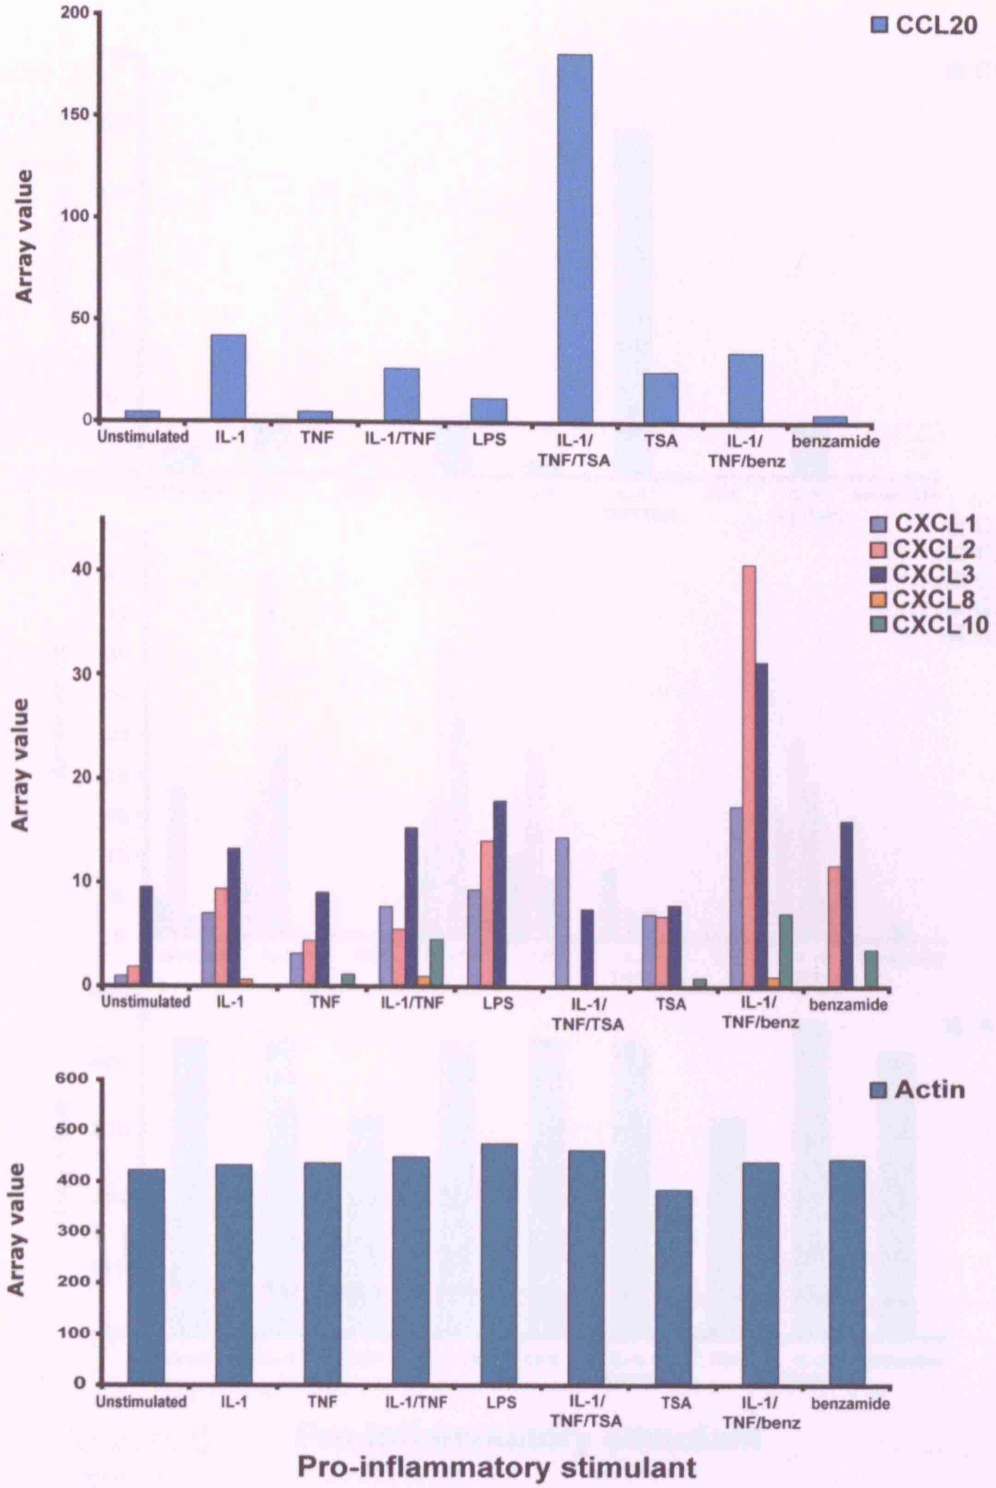
Graph 5.1 demonstrates chemokine induction following pro-inflammatory stimulation at 2 hours as measured by microarray analysis. Caco-2 cellular expression of CCL20, CXCL's1-3 and CXCL8 are primarily up regulated by IL-1β, without synergism by TNF-α. There is a consistent hybridisation signal for actin in all 2-hour samples analysed.

Graph 5.2: 2-hour chemokine expression levels from microarray analysis of Caco-2 cells post pro-inflammatory stimulation (passage 22).



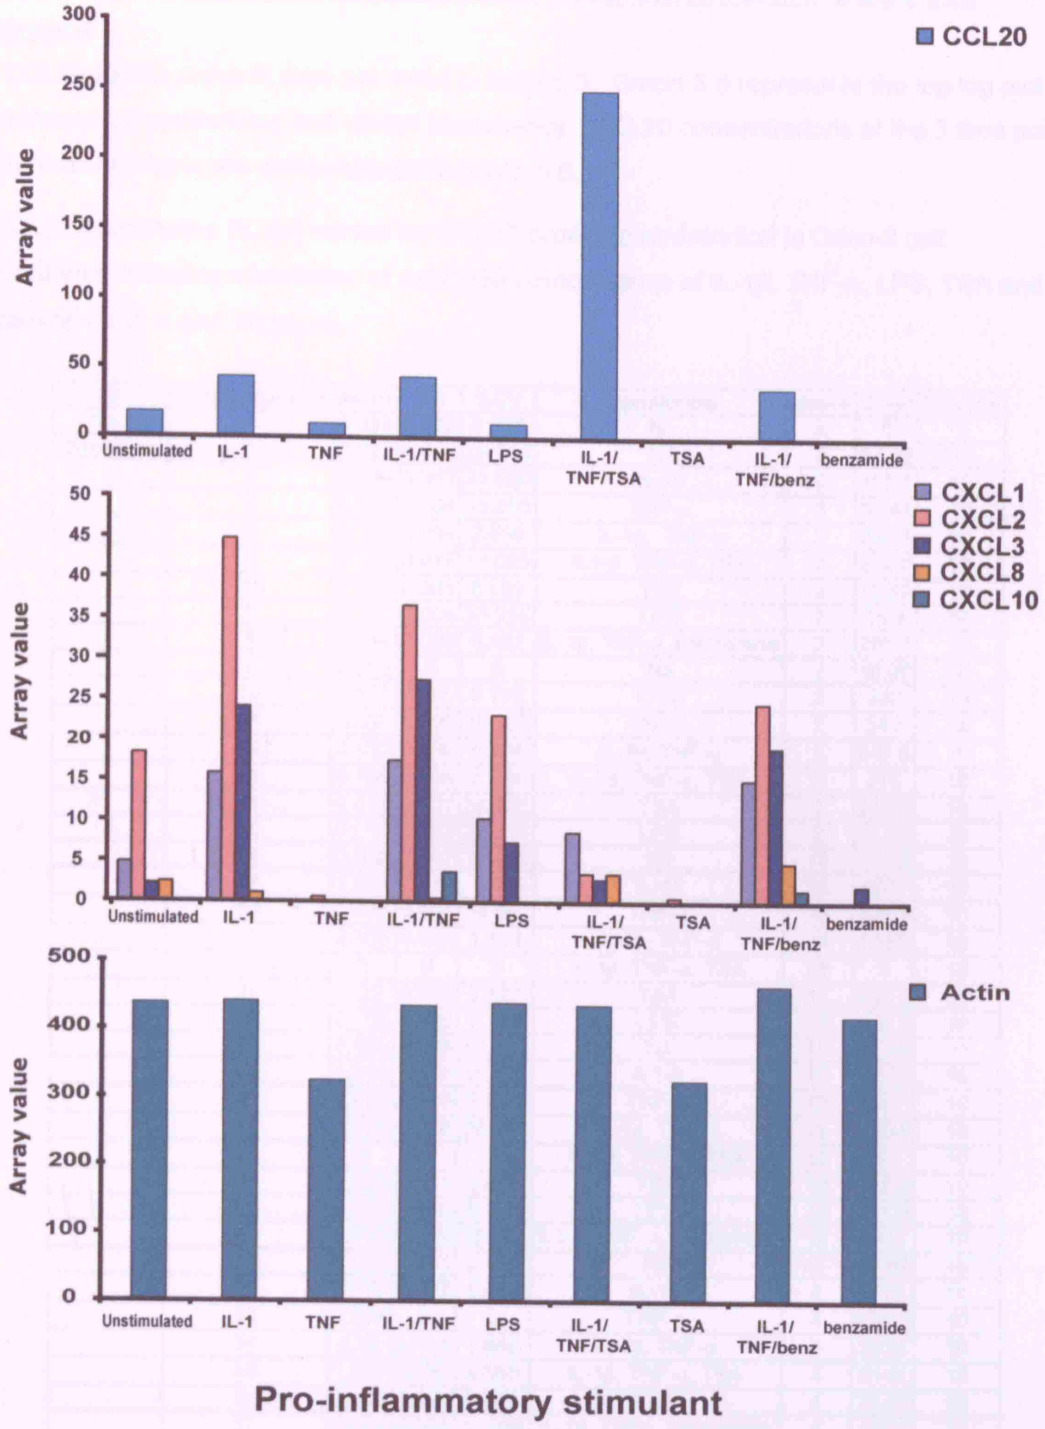
Graph 5.2 demonstrates chemokine induction following pro-inflammatory stimulation at 2 hours as measured by microarray analysis. Caco-2 cellular expression of CCL20, CXCL1-3's and CXCL8 are primarily up regulated by IL-1β, without synergism by TNF-α. There is a consistent hybridisation signal for actin in all 2-hour samples analysed.

Graph 5.3: 18-hour chemokine expression levels from microarray analysis of Caco-2 cells post pro-inflammatory stimulation (passage 4).



Graph 5.3 demonstrates chemokine induction following pro-inflammatory stimulation at 18 hours as measured by microarray analysis. Caco-2 cellular expression of CCL20, CXCL1-3's and CXCL8 are primarily up regulated by IL-1β, without synergism by TNF-α. There is a consistent hybridisation signal for actin in all 18-hour samples analysed.

Graph 5.4: 18-hour chemokine expression levels from microarray analysis of Caco-2 cells post pro-inflammatory stimulation (passage 22).



Graph 5.4 demonstrates chemokine induction following pro-inflammatory stimulation at 18 hours as measured by microarray analysis. Caco-2 cellular expression of CCL20, CXCL1-3's and CXCL8 are primarily up regulated by IL-1β, without synergism by TNF-α. There is a consistent hybridisation signal for actin in all 18-hour samples analysed.

5.2.4 Quantitative determination of chemokine protein concentrations in stimulated Caco-2 cell supernatants

ELISA was performed on Caco-2 supernatants, as outlined in 2.2.5.

5.2.4.1 Quantitative determination of CCL20 protein concentration in Caco-2 cells supernatant

The CCL20 ELISA curve fit data are listed in table 5.3. Graph 5.5 represents the log-log plot of the standard concentrations and optical absorbency. CCL20 concentrations at the 3 time points in different conditions are demonstrated in graph 5.6.

Table 5.3: Quantitative ELISA values for CCL20 protein concentration in Caco-2 cell supernatants, following stimulation of cells with combinations of IL-1β, TNF-α, LPS, TSA and benzamide for 2, 4 and 18 hours.

5.2.4 Quantitative determination of chemokine protein concentrations in stimulated Caco-2 cell supernatants

ELISA was performed on Caco-2 supernatants, as outlined in 2.2.5.

5.2.4.1 Quantitative determination of CCL20 protein concentration in Caco-2 cells supernatant

The CCL20 ELISA curve fit data are listed in table 5.3. Graph 5.5 represents the log-log plot of the standard concentrations and optical absorbency. CCL20 concentrations at the 3 time points in different conditions are demonstrated in graph 5.6.

Table 5.3: Quantitative ELISA values for CCL20 protein concentration in Caco-2 cell supernatants, following stimulation of cells with combinations of IL-1β, TNF-α, LPS, TSA and benzamide for 2, 4 and 18 hours.

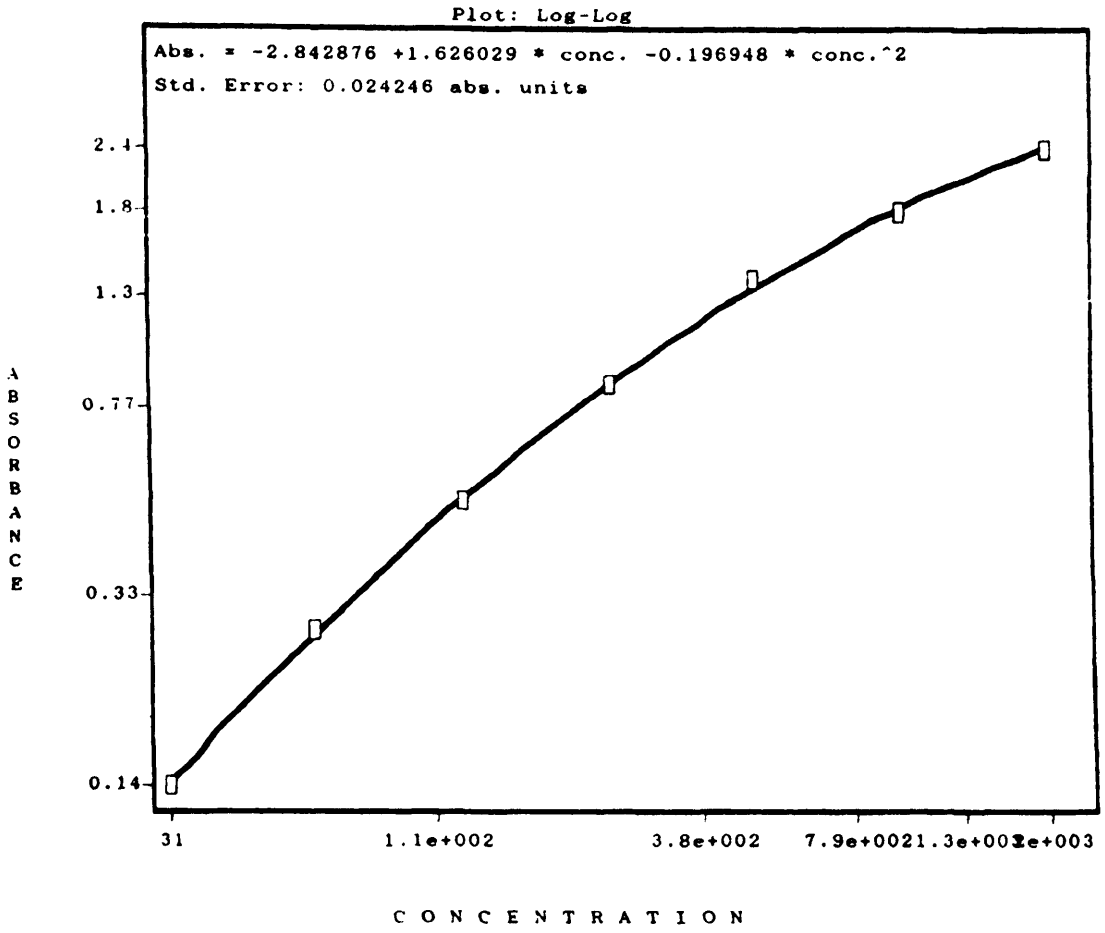
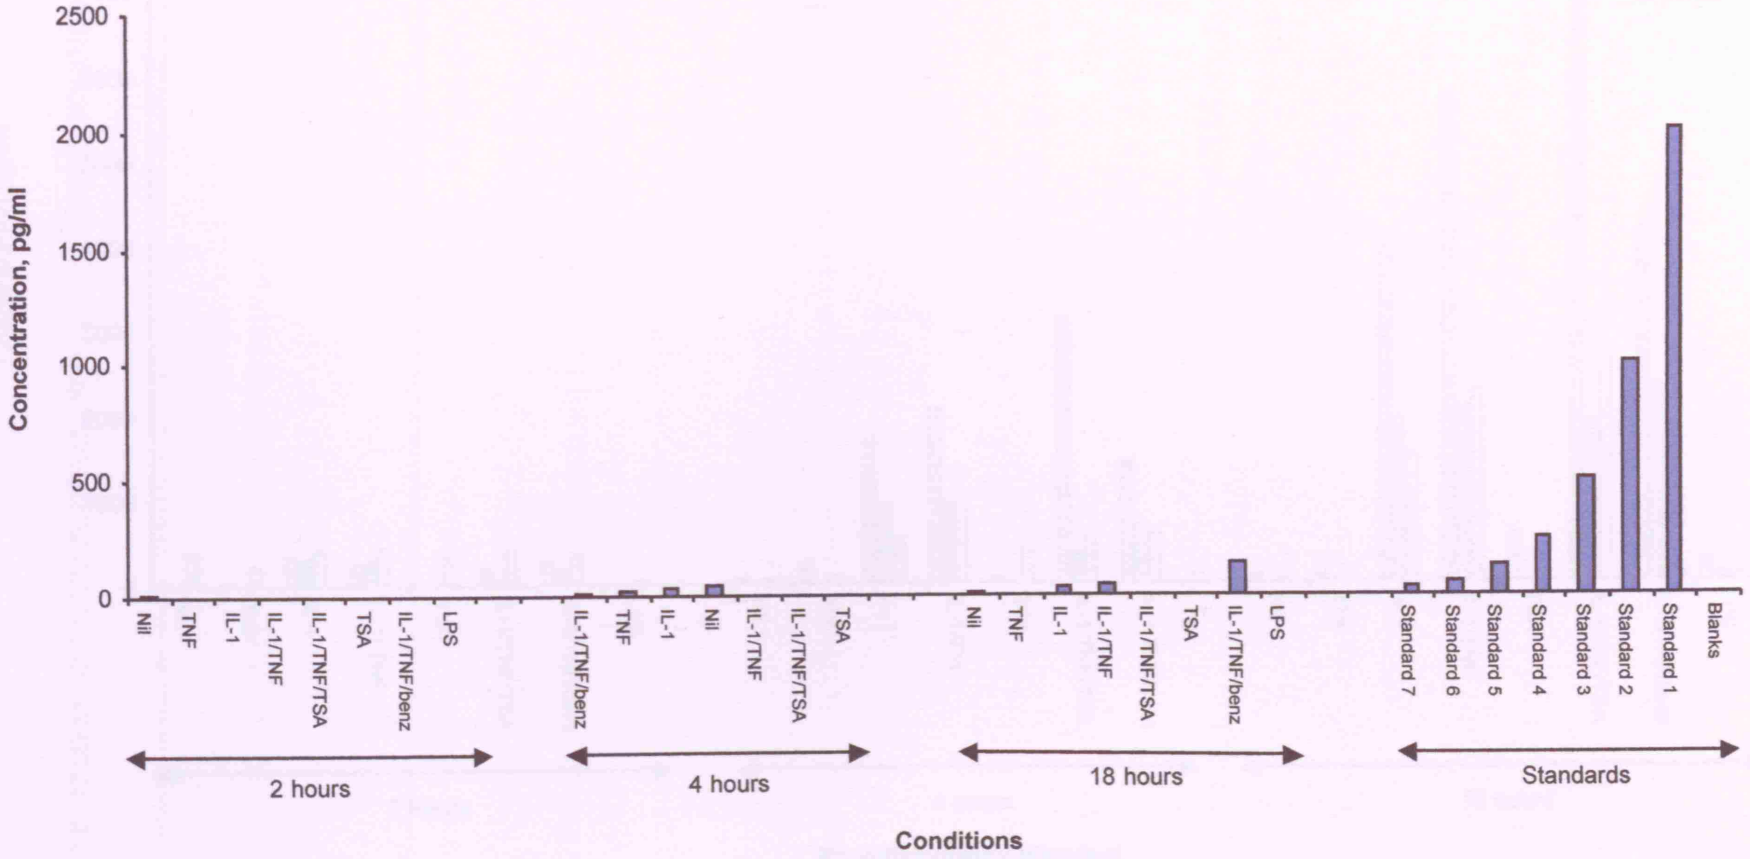
Graph 5.11: Log-log plot of CCL5 standard concentrations and optical absorbency

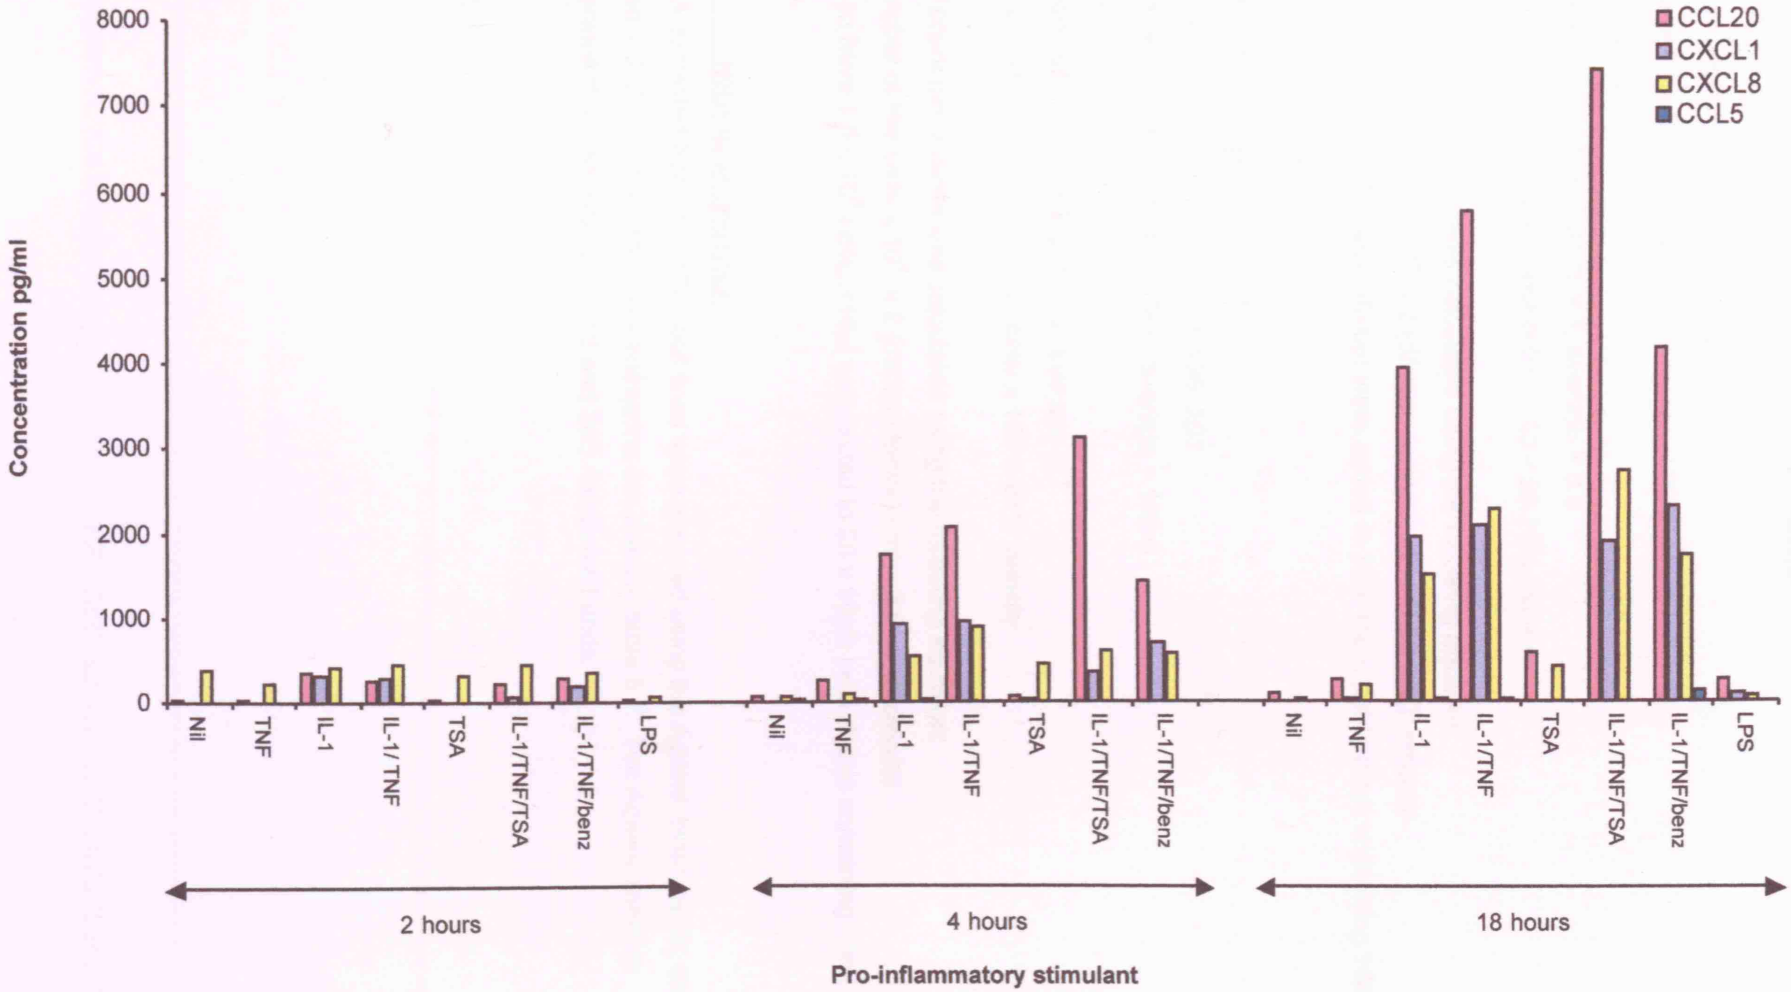


Graph 5.12: Concentrations of CCL5 protein in supernatants of stimulated Caco-2 cells at 2, 4 and 18 hours



Graph 5.12 demonstrates no significant increase of CCL5 follwing pro-inflammatory stimulation.

Graph 5.13: Quantitative CCL20, CXCL1, CXCL8 and CCL5 protein concentration in stimulated Caco-2 cell supernatants at 2, 4, 18 hours



Graph 5.13 demonstrates that there is some synergy between IL-1 and TNF, althogh TNF alone had little chemokine stimulatory effect. TSA increases the induction of CCL20 and CXCL8. The ELISA data are consistent with the array data.

5.3 Coordinate chemokine response in stimulated HT29 cells

5.3.1 HT29 cell count and viability assessment

Cell counts for passage number 4:

Live cell counts: 71, 54, 77, 91, 72, 92

Total live cell count in 6 grids = 457, average = 76.2

Dead cell counts: 0, 0, 1, 1, 0, 1

Total dead cell counts in 6 grids = 3, average = 0.5

Number of live cells / total number cells x 100 = 99.25% viability

The cell count per volume was calculated using the following equation:

Total number of live cells x 10^4 x 2 (dilution factor) / ml = 1.523 x 10^6 cells/ml

In order to have 1.5 x 10^6 cells, 1000µl were added to 30 x 10cm petri dishes containing 10ml medium.

Cell counts for passage number 6:

Live cell counts: 193, 175, 170, 149, 196, 201

Total live cell count in 6 grids = 1084, average = 180.6

Dead cell counts: 2, 3, 3, 1, 6, 7

Total dead cell counts in 6 grids: 22, average 3.7

Number of live cells / total number cells x 100 = 98% viability

The cell count per volume was calculated using the following equation:

Total number of live cells x 10^4 x 2 (dilution factor) / ml = 3.6 x 10^6 cells/ml

In order to have 1.5 x 10^6 cells, 416µl was added to 20 x 10cm petri dishes containing 10ml medium.

5.3.2 RNA quantification

The RNA extracted from the HT29 cell lines were assayed using the Agilent bioanalyser, as described in 2.2.1.4. The RNA concentrations are listed in table 5.7. The Agilent analysis demonstrated the presence of the 18 and 28S ribosomal bands.

Table 5.7: Details of stimulatory conditions used in HT29 cell culture, corresponding with semi-quantified RNA concentrations (ng/μl) obtained via the Agilent bioanalyser.

Sample description	RNA Concentration (ng/μl)	rRNA ratio 28S/18S
Nil added, 2 hours	797.33	1.63
IL-1β added, 2hours	433.27	1.67

5.4 Coordinate chemokine response in stimulated primary colonic epithelial cells

5.4.1 Primary colonic epithelial microarray results

Primary colonic epithelial cells were stimulated as described in 2.2.8. The biopsies were obtained from patient 28-colonoscopy study 1. This patient had UC. The results are listed in table 5.10, and graphically represented in figure 5.18.

Table 5.10: 2-hour and 4-hour normalised CXCL's1-3, CXCL8, CXCL10, CCL20, actin expression levels from microarray analysis of primary colonic epithelial cells stimulated with nil/IL-1β/ TNF-α/IL-1β + TNF-α/LPS.

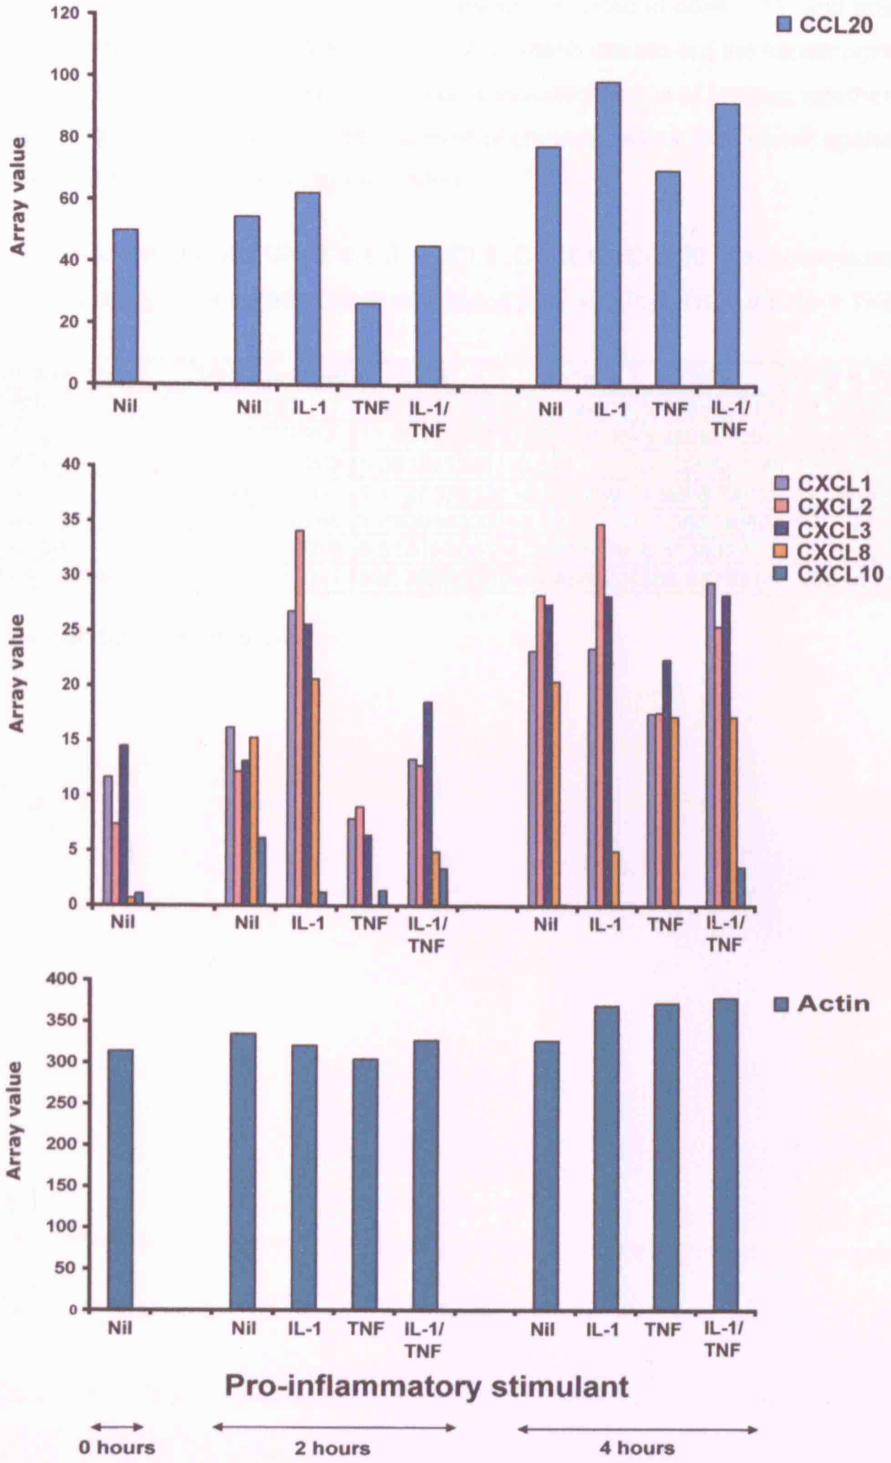
Graph 5.17: 2-hour and 4-hour chemokine expression levels from microarray analysis of primary colonic epithelial cells post pro-inflammatory stimulation.



Graph 5.17 demonstrates induction of CCL20, CXCL's1-3 and CXCL8 in cultured primary colonic epithelial cells following stimulation with IL-1β or TNF-α. The results are of limited value as one set of biopsies were included in this study.

5.5 Coordinate chemokine response in stimulated keratinocytes and lung primary epithelial cells

Celltech group members found synergy between IL-1β and TNF-α for induction of CCL20, CXCL's 1-3 and CXCL8 in keratinocytes. The results are listed in table 5.11, and graphically represented in graph 5.19. Mr S Makh, at Slough Celltech carried out the keratinocyte cell culture (Platt et al, unpublished data). The data is included as it is of interest whether non-mucosal epithelial cells express the same subset of chemokines as the colonic epithelial cell lines in response to pro-inflammatory stimulation.

Table 5.11: 2-hour normalised CXCL's 1-3, CXCL8, CXCL10, CCL20, actin expression levels from microarray analysis of keratinocytes stimulated with nil/IL-1β/ TNF-α/IL-1β + TNF-α/LPS.

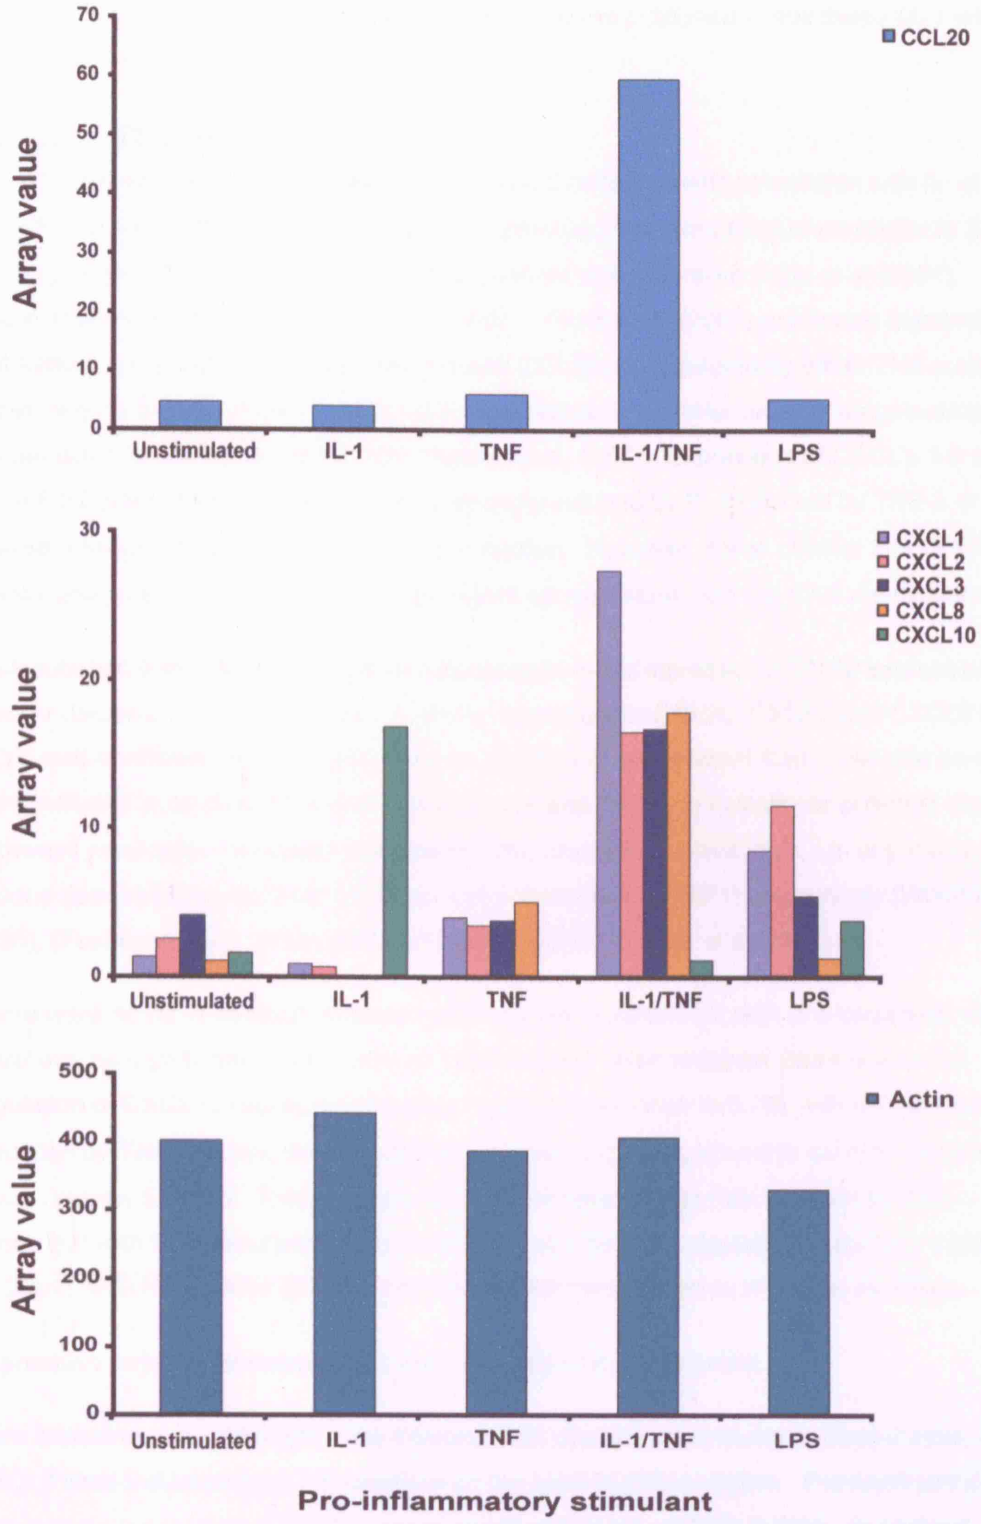
(18-hour data not available)

Graph; 5.18: 2-hour chemokine expression levels from microarray analysis of stimulated keratinocytes.



Graph 5.18 demonstrates synergy between IL-1β and TNF-α for induction of CCL20, CXCL's1-3 and CXCL8 in keratinocytes. The actin array levels were consistent.

Celltech group members found the same coordinated chemokine response following combined IL-1β and TNF-α stimulation of a lung epithelial primary cell line, human bronchial epithelium. This data is subject to company confidentiality, so is not published in this thesis (A. Platt et al, unpublished, personal communication).

5.6 Discussion

CCL20 expression was strongly induced in Caco-2 cells following stimulation with IL-1β but not by TNF-α or LPS, while levels of expression following dual stimulation were similar to IL-1β alone (graphs 5.1-5.4, 5.6, 5.13). This is consistent with data from Fujiie et al (2001), Izadapanah et al (2001), and Kwon et al (2002). Fujiie et al, (2001) previously demonstrated that human colon carcinoma cell lines express CCL20, up regulated by either TNF-α or IL-1β depending on lineage. Caco-2 cells secrete cytokines in a similar order of magnitude to that of normal isolated colonic epithelial cells (Huang et al, 1997). Expression of CXCL's 1-3 and CXCL8 followed the same pattern, being strongly induced by IL-1β but not by TNF-α or LPS, dual stimulation being equivalent to IL-1β induction. However, it was notable that CCL20 mRNA and protein showed substantially higher up regulation than the CXC chemokines.

Co-incubation with TSA resulted in an approximate 2-fold increase in CCL20 expression and a modest decrease in CXCL3 levels. A similar response for CCL20, CXCL1 and CXCL8 but not CCL5 was confirmed at the protein level on analysis of supernatant fluid. TSA and benzamide were included in co incubation studies with IL-1β and TNF-α to investigate potential regulatory pathways previously implicated in epithelial CXC chemokine production, i.e. any involvement of histone deacetylation and poly (ADP-ribose) polymerase (PARP1) respectively (Wood et al, 1995), (Fusunyan et al, 1999), (Ashburner et al, 2001), (Nirodi et al, 2001).

There were no other obvious induction of chemokine expression, with one exception: although there was no significant up regulation in inflamed IBD colon biopsies, there was an up regulation of CXCL10 expression by Caco-2 cells in response to IL-1β, with only a small induction by TNF-α alone, the dual stimulation resulting in a cumulative expression level at 18 hours (graphs 5.1-5.4). This induced CXCL10 expression was fully inhibited by TSA, consistent with its distinct pathway of induction via interferon regulatory factor (IRF)-3 (Kawai et al, 2001), which regulates gene expression by histone acetylation (Panja et al, 1998).

Expression levels of all chemokines were unaffected by benzamide.

Care should be taken though in the interpretation of expression levels in Caco-2 cells, as CXCL8 level induction by IL-1β depends on the level of differentiation. Pre-confluent Caco-2 cells can be induced by IL-1β to express significant levels of CXCL8 RNA. In contrast, differentiated post-confluent cells express much less CXCL8 mRNA in response to IL-1β (Huang et al, 1997). In order to ensure that the results were not merely anomalous to Caco-2 cells, HT29 cells study was important. The inflammatory response in Caco-2 cells, as in

isolated colonocytes, can be initiated by Il-1β but not TNF-α. This is in contrast to most other colon cancer cell lines, which respond to stimulation with either IL-1β or TNF-α.

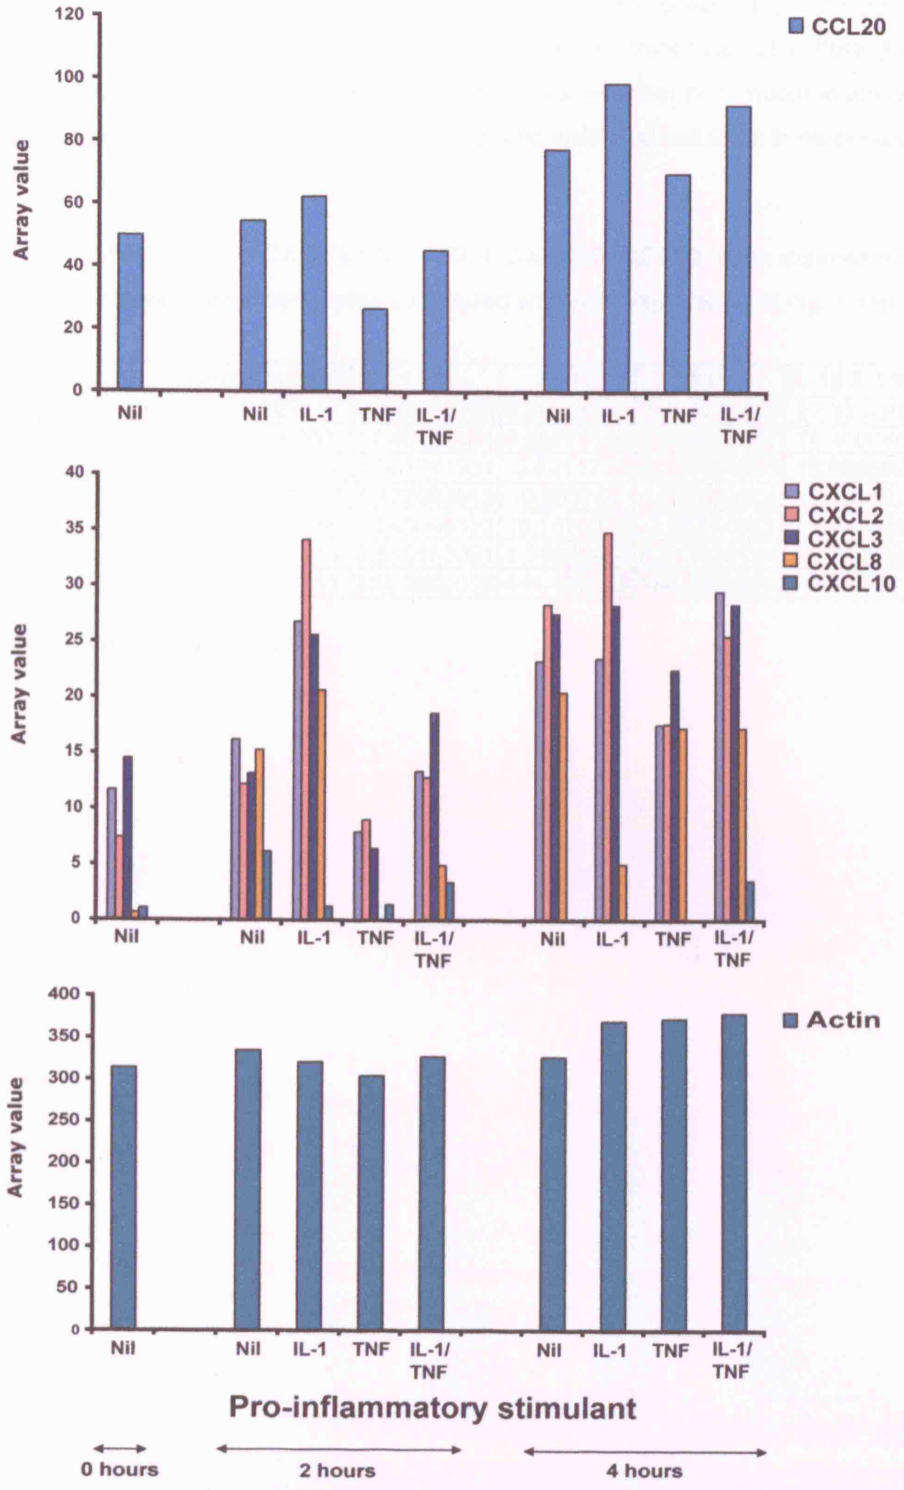
In contrast to Caco-2 cells, stimulation of HT-29 cells with TNF-α resulted in a significant induction of CCL20 expression (graph 5.14) consistent with previous observations (Izadapanah et al, 2001), (Kwon et al, 2002). IL-1β and IL-1β+TNF-α stimulation also resulted in a significant up regulation of CCL20, although dual stimulation was not synergistic. Expression of CXCL's 1-3 and CXCL8 was significantly induced following treatment with either IL-1β, TNF-α, or IL-1β and TNF-α together. No other chemokine was observed to significantly up regulated following treatment with IL-1β and/or TNF-α.

The primary colonic epithelial cell cultures results were of limited value, as biopsies were only included from one patient. This was undertaken as a pilot study rather than for purposes of scientific conclusions.

Keratinocyte cell culture studies were undertaken to determine if non-mucosal epithelial cells expressed the same subset of chemokines as stimulated Caco-2 and HT-29 cells. In contrast to the Caco-2 cells, IL-1β alone did not stimulate significant levels of expression of CXCL's1-3, CXCL8 and CCL20 in primary keratinocytes, but simultaneous stimulation with TNF-α did induce the coordinated chemokine response. This is consistent with Nakayama et al (2001), who demonstrated greatly increased levels of CCL20 expression when keratinocytes were stimulated with IL-1β and TNF-α in concert.

The same coordinated chemokine response was seen following combined IL-1β and TNF-α stimulation of a lung epithelial primary cell line, human bronchial epithelium (A. Platt et al, unpublished, personal communication).

Graph 5.17: 2-hour and 4-hour chemokine expression levels from microarray analysis of primary colonic epithelial cells post pro-inflammatory stimulation.



Graph 5.17 demonstrates induction of CCL20, CXCL's1-3 and CXCL8 in cultured primary colonic epithelial cells following stimulation with IL-1β or TNF-α. The results are of limited value as one set of biopsies were included in this study.

5.5 Coordinate chemokine response in stimulated keratinocytes and lung primary epithelial cells

Celltech group members found synergy between IL-1β and TNF-α for induction of CCL20, CXCL's1-3 and CXCL8. The results are listed in table 5.11, and graphically represented in graph 5.19. Mr S Makh, at Slough Celltech carried out the keratinocyte cell culture (Platt et al, unpublished data). The data is included as it is of interest whether non-mucosal epithelial cells express the same subset of chemokines as the colonic epithelial cell lines in response to pro-inflammatory stimulation.

Table 5.11: 2-hour normalised CXCL's1-3, CXCL8, CXCL10, CCL20, actin expression levels from microarray analysis of keratinocytes stimulated with nil/IL-1β/ TNF-α/IL-1β + TNF-α/LPS.

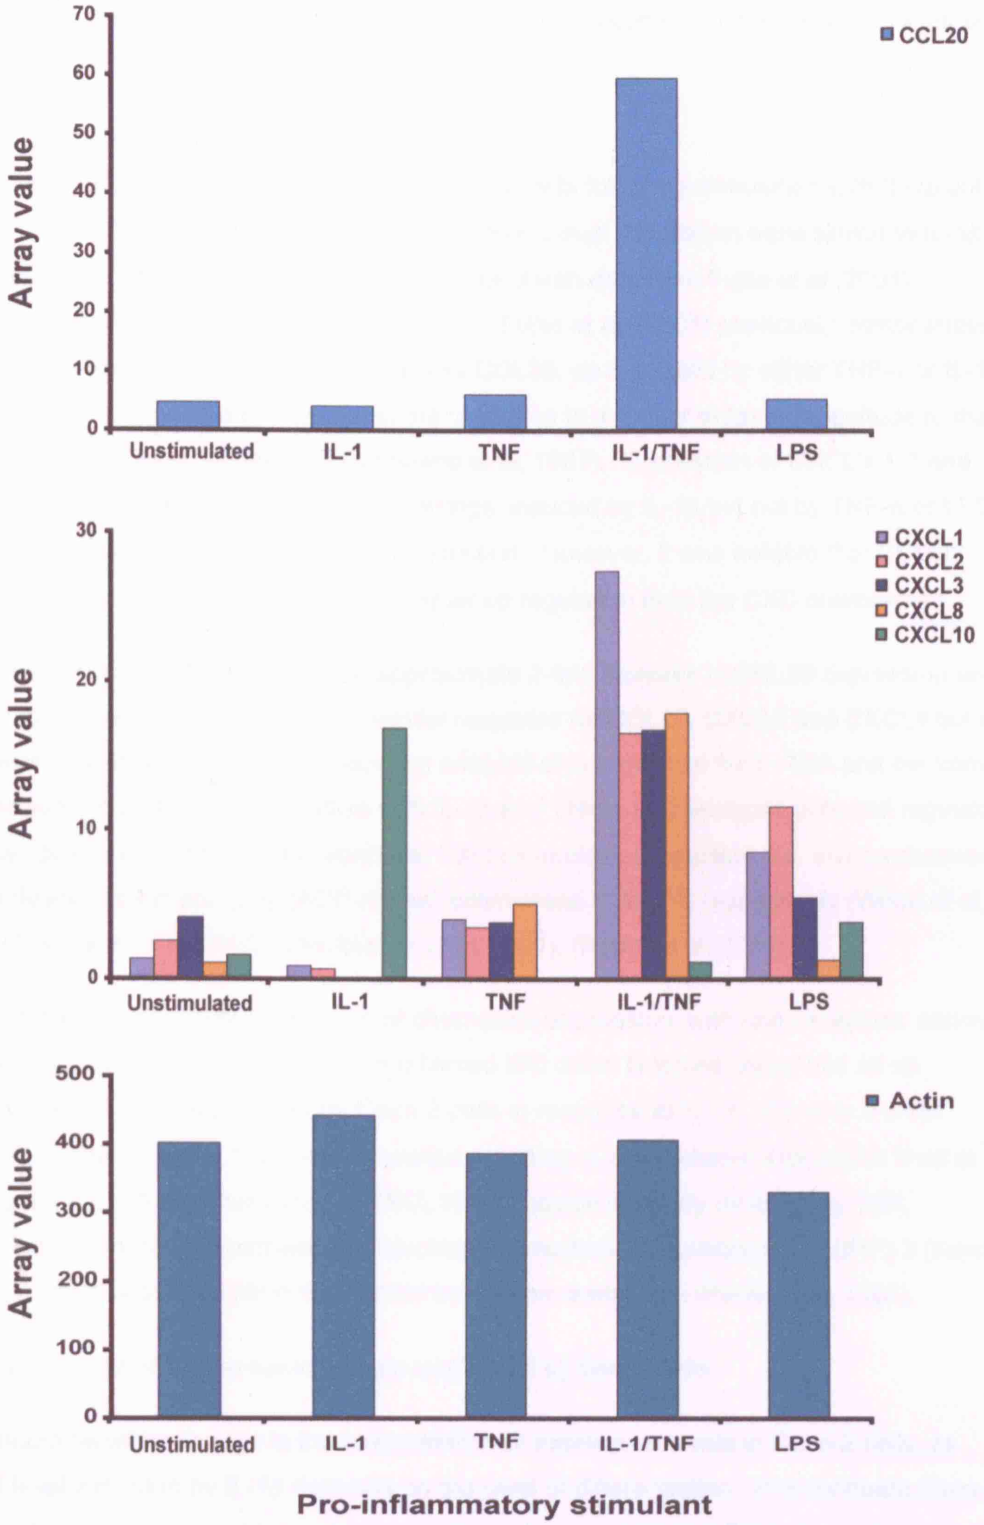
(18-hour data not available)

Graph; 5.18: 2-hour chemokine expression levels from microarray analysis of stimulated keratinocytes.



Graph 5.18 demonstrates synergy between IL-1β and TNF-α for induction of CCL20, CXCL's1-3 and CXCL8 in keratinocytes. The actin array levels were consistent.

Celltech group members found the same coordinated chemokine response following combined IL-1β and TNF-α stimulation of a lung epithelial primary cell line, human bronchial epithelium. This data is subject to company confidentiality, so is not published in this thesis (A . Platt et al, unpublished, personal communication).

5.6 Discussion

CCL20 expression was strongly induced in Caco-2 cells following stimulation with IL-1β but not by TNF-α or LPS, while levels of expression following dual stimulation were similar to IL-1β alone (graphs 5.1-5.4, 5.6, 5.13). This is consistent with data from Fujiie et al (2001), Izadapanah et al (2001), and Kwon et al (2002). Fujiie et al, (2001) previously demonstrated that human colon carcinoma cell lines express CCL20, up regulated by either TNF-α or IL-1β depending on lineage. Caco-2 cells secrete cytokines in a similar order of magnitude to that of normal isolated colonic epithelial cells (Huang et al, 1997). Expression of CXCL's 1-3 and CXCL8 followed the same pattern, being strongly induced by IL-1β but not by TNF-α or LPS, dual stimulation being equivalent to IL-1β induction. However, it was notable that CCL20 mRNA and protein showed substantially higher up regulation than the CXC chemokines.

Co-incubation with TSA resulted in an approximate 2-fold increase in CCL20 expression and a modest decrease in CXCL3 levels. A similar response for CCL20, CXCL1 and CXCL8 but not CCL5 was confirmed at the protein level on analysis of supernatant fluid. TSA and benzamide were included in co incubation studies with IL-1β and TNF-α to investigate potential regulatory pathways previously implicated in epithelial CXC chemokine production, i.e. any involvement of histone deacetylation and poly (ADP-ribose) polymerase (PARP1) respectively (Wood et al, 1995), (Fusunyan et al, 1999), (Ashburner et al, 2001), (Nirodi et al, 2001).

There were no other obvious induction of chemokine expression, with one exception: although there was no significant up regulation in inflamed IBD colon biopsies, there was an up regulation of CXCL10 expression by Caco-2 cells in response to IL-1β, with only a small induction by TNF-α alone, the dual stimulation resulting in a cumulative expression level at 18 hours (graphs 5.1-5.4). This induced CXCL10 expression was fully inhibited by TSA, consistent with its distinct pathway of induction via interferon regulatory factor (IRF)-3 (Kawai et al, 2001), which regulates gene expression by histone acetylation (Panja et al, 1998).

Expression levels of all chemokines were unaffected by benzamide.

Care should be taken though in the interpretation of expression levels in Caco-2 cells, as CXCL8 level induction by IL-1β depends on the level of differentiation. Pre-confluent Caco-2 cells can be induced by IL-1β to express significant levels of CXCL8 RNA. In contrast, differentiated post-confluent cells express much less CXCL8 mRNA in response to IL-1β (Huang et al, 1997). In order to ensure that the results were not merely anomalous to Caco-2 cells, HT29 cells study was important. The inflammatory response in Caco-2 cells, as in

isolated colonocytes, can be initiated by Il-1β but not TNF-α. This is in contrast to most other colon cancer cell lines, which respond to stimulation with either IL-1β or TNF-α.

In contrast to Caco-2 cells, stimulation of HT-29 cells with TNF-α resulted in a significant induction of CCL20 expression (graph 5.14) consistent with previous observations (Izadapanah et al, 2001), (Kwon et al, 2002). IL-1β and IL-1β+TNF-α stimulation also resulted in a significant up regulation of CCL20, although dual stimulation was not synergistic. Expression of CXCL's 1-3 and CXCL8 was significantly induced following treatment with either IL-1β, TNF-α, or IL-1β and TNF-α together. No other chemokine was observed to significantly up regulated following treatment with IL-1β and/or TNF-α.

The primary colonic epithelial cell cultures results were of limited value, as biopsies were only included from one patient. This was undertaken as a pilot study rather than for purposes of scientific conclusions.

Keratinocyte cell culture studies were undertaken to determine if non-mucosal epithelial cells expressed the same subset of chemokines as stimulated Caco-2 and HT-29 cells. In contrast to the Caco-2 cells, IL-1β alone did not stimulate significant levels of expression of CXCL's1-3, CXCL8 and CCL20 in primary keratinocytes, but simultaneous stimulation with TNF-α did induce the coordinated chemokine response. This is consistent with Nakayama et al (2001), who demonstrated greatly increased levels of CCL20 expression when keratinocytes were stimulated with IL-1β and TNF-α in concert.

The same coordinated chemokine response was seen following combined IL-1β and TNF-α stimulation of a lung epithelial primary cell line, human bronchial epithelium (A. Platt et al, unpublished, personal communication).

Chapter 6

Flow cytometric analysis on mucosally derived cells

6.1 Background

6.2 Results

6.3 Discussion

6.1 Background

Tissue was taken from surgically removed colon, from patients with IBD or colonic carcinoma. In the former, 2 square cm of tissue were taken from 3 separate areas. In the latter, 1 square cm was taken from 1 normal area. This was done with full consent of the patients, and with full ethical approval.

Flow cytometric analysis was performed on mucosally derived cells extracted from 3 colectomy specimens (1 uninflamed control, requiring resection for colon carcinoma, 1 with UC and 1 with CD). The method used is described in 2.2.5. Several sites were examined from each specimen, including both severely inflamed and mildly inflamed areas from both IBD specimens.

6.2 Results

Separate examination of both lamina propria and epithelial compartments showed widespread expression of the cognate chemokine receptors in both inflamed and control tissue, involving antigen presenting cells, B and T lymphocytes and monocytes. The intensity of CCL20 expression on epithelial cells was enhanced in IBD specimens, particularly in severe disease (graph. 6.1A). Increased percentages of $CCR6^+$ CD14 cells, and $CXCR1^+$ and $CXCR2^+$ cells of all lineages were detected. In addition to $CD45^+$ leukocytes (graph 6.1 B, C, D), CXCR's 1 and 2 were expressed on CD3, CD4 and CD8 T cells, CD19 B cells, and CD138 plasma cells, in addition to CD14 monocytes and cells expressing Fcγ receptors I and II (CD16, CD32) and CD86. The proportion of $CCR6^+$ cells was lower, except amongst antigen presenting cells, but $CCR6^+$ cells were identified in both T and B cells compartments and monocytes.

6.3 Discussion

The cognate receptors for the chemokine subset, CXCR1, CXCR2 and CCR6, were up regulated on T and B lymphocytes, macrophages, polymorph neutrophils and antigen presenting cells.

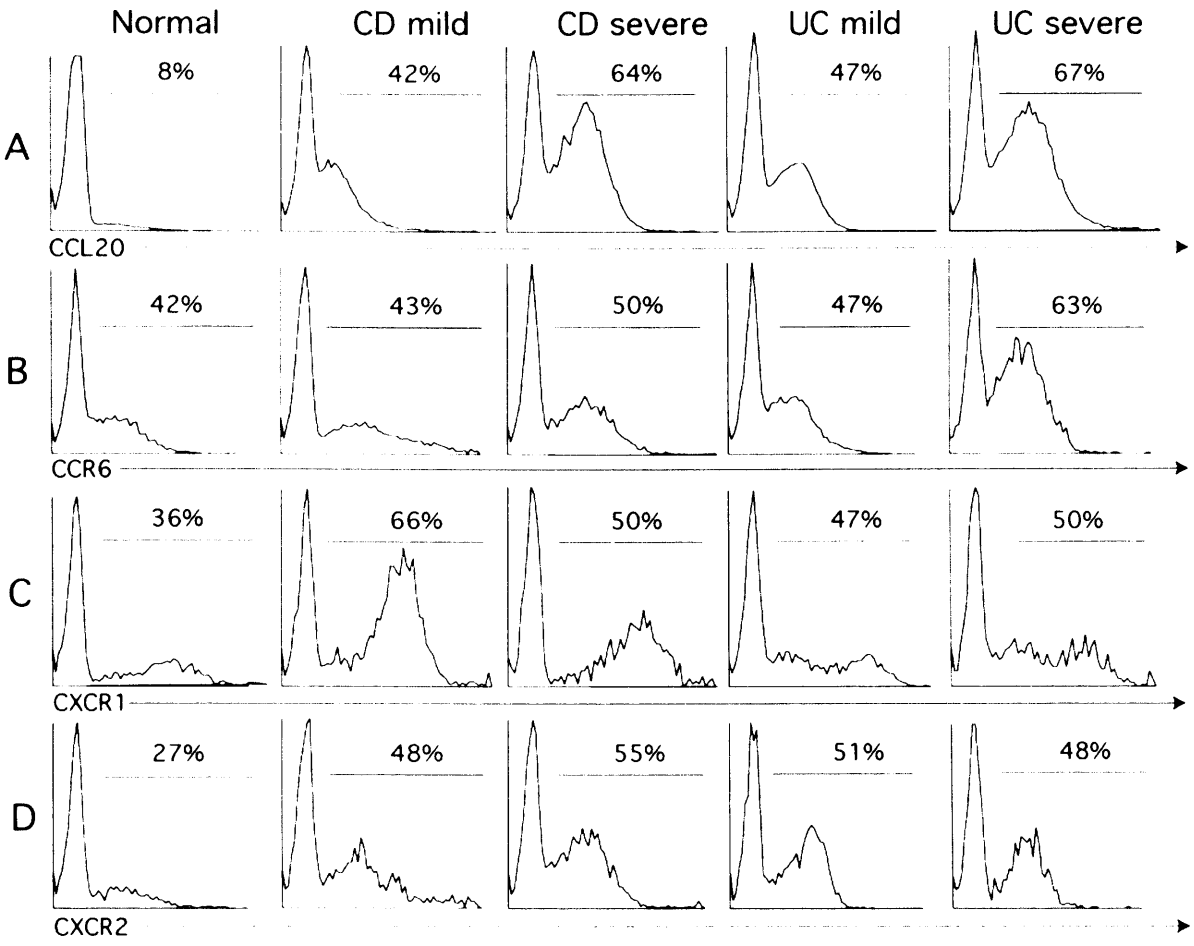
Graph 6.1: Flow cytometric analysis of chemokine and ligand expression in normal colon compared to CD (mildly inflamed and severe) and UC (mildly inflamed and severe), including CCL20, CCR6, CXCR1, CXCR2.

A. CCL20 in cytokeratin$^+$ colonocytes. Compared to normal colonocytes, there is substantially increased frequency of CCL20$^+$ cells in active IBD, with further increase in severely inflamed tissue.

B. CCR6 expression in lamina propria CD14$^+$ cells, showing increase in severe UC.

C. CXCR1 expression is increased on CD45$^+$ lamina propria cells in active disease.

D. CXCR2 expression shows similar increase amongst CD45$^+$ lamina propria cells in active disease.



Chapter 7

Immunohistochemical localisation and quantification of CCL20 and CCR6 in necrotising enterocolitis, using the immunoperoxidase technique

7.1 Background

7.2 H&E and immunohistochemical staining of NEC and control tissue to investigate potential immune-neural interactions

7.3 Results

7.4 Discussion

7.1 Background

Necrotising enterocolitis (NEC) is a necrotic ulcerative bowel disorder in neonates. Approximately 50% of babies developing NEC require surgery, and the mortality rate of NEC is 20-40%. Of those who survive, approximately 25% develop long term sequelae. Research into this condition is therefore of great importance.

The aetiology is unknown, although predisposing factors include: extreme prematurity, formula feeds, dysmotility, reduced mesenteric blood flow, dysbiosis. Ninety percent of babies with NEC are pre-term.

Several groups are currently investigating the fundamental centrality of ganglionic nerve plexus pathology as a potential primary cause of the disorder. NEC-like lesions have been induced experimentally by targeted deletion of enteric glial cells in transgenic mice (Bush et al, 1998). Two groups have found a characteristic loss of nerve cells within the plexus, with absence of vasoactive intestinal polypeptide and nitric oxide synthetase (Sigge et al, 1998), (Wedel et al, 1998).

There are a number of features in common with IBD, such as the characteristic mucosal ulceration. As the receptor/ligand pair CCL20/CCR6 are of pivotal importance in IBD, their expression in necrotising enterocolitis is of great interest.

7.2 H&E and immunohistochemical staining of NEC and control tissue to investigate potential immune-neural interactions

The paediatric gastroenterology group at the Royal Free Hospital have been studying potential immune-neural interactions, including lymphocyte infiltrate, neural structures, and glial cells using immunohistochemical staining of the following:

- *Immunological:* CD3 (T cell marker), HLA-DR (Class II MHC), IL-12 (Th1-assocaited cytokine, TGF-β (regulatory cytokine)
- *Neural / glial:* Glial Fibrillary Acidic Protein (GFAP), Nerve Growth Factor Receptor (NGFR), Neural Fibrillary Protein (NFP), Neuron Specific Enolase (NSE)

The method used is as described in 2.2.3, by a member of the paediatric research group, Dr Fagbemi. The study cohort included 20 infants with NEC, (mean gestation 29 weeks (25-33), body weight 1050g (500-2340), surgery at 17 days (3-41); 11 small bowel, 8 ileocaecal, 1 colonic resection, and follow-up specimens at ileostomy closure in 8. The non-NEC controls included 13 pre-term infants (33-38 weeks gestation, 2000-2980g) who required intestinal resection (1-60 days); 6 with small bowel atresia, 4 with perforation, 2 with mesenteric infarction and 1 with bowel stenosis. In view of the demonstrated mucosal significance of CCL20/CCR6 in IBD, the sections were also stained for CCL20 and CCR6 using the methods described in 2.2.3.

7.3 Results

Microscopic examination of H&E stained bowel sections, and immunohistochemically-stained sections for neural fibrillary protein and neural growth factor (NGFR) enabled identification of a number of differences between NEC and control sections, as demonstrated in figure 7.1-7.3. The myenteric and submucous plexi were intact in all controls, although there was neural disruption observed in NEC cases, with intact innervation in 8/20, loss of submucus plexi and mucosal nerves in 10/20, patchy loss in 2/20. In NEC, there was submucosal neural disruption associated with loss of glial cells in myenteric plexus, and a focal lymphocyte infiltration seen in myenteric plexi. Neural disruption was not related to disease severity seen even if inflammation was apparently limited to mucosa. The neural disruption was strongly associated with myenteric plexus abnormalities.

Immunohistochemical staining of CCR6 and CCL20 demonstrated expression in NEC (figure 7.4, tables 7.1, 7.2). Follow-up at ileostomy closure demonstrated normal innervation pattern in 6/8. There was persistent disruption in 2/8, with a complex course with recurrent NEC and persistent glial CCL20 expression (negative in the other 6 cases).

7.4 Discussion

There was perineural T cell infiltration and glial disruption occurred in the myenteric plexus of 12/20 infants with NEC. This response was focal, associated with disruption of the submucosal plexi and mucosal nerves. Glial cells were immunoreactive for effector cytokines and chemokines: CCL20 is a potential cause of T cell infiltration. These changes may contribute to dysmotility and inflammation in NEC. Experimental data suggests that glial loss alone may induce NEC-like lesion, and raises the possibility of primary neural pathology in some cases. The cause for the focal glial CCL20 expression and T cell infiltration remain uncertain, though viral infection more likely than bacterial translocation. Chronic cases may be autoimmune related.

Chapter 8

Discussion and conclusion

8.1 Discussion
8.2 Conclusions

8.1 Discussion

Collective data from the research presented, incorporating colonic tissue microarray and RT-PCR, immunohistochemistry, cultured cell lines from colon, skin, and lung epithelia, and flow cytometry demonstrate a previously unrecognised coordinated epithelial chemokine response in active IBD, including CXCL's 1-3, CXCL8 and CCL20. This is the first report of coordinated expression of a distinct subset of the chemokine superfamily within human tissue. The four major CXC chemokines from the 4q.12 cluster, CXCL's 1-3 and 8 are up regulated together with the CC chemokine CCL20, with inducing stimulus varying with cell lineage. Chemokine receptors CXCR's 1 and 2 and CCR6, were also up regulated, primarily on T and B lymphocytes, macrophages, polymorph neutrophils and antigen presenting cells.

The proposed pathogenic mechanism for IBD incorporates an excessive immune response to environmental factors such as intestinal pathogens involving the chemokine subset described, in genetically susceptible individuals. Evidence indicates that rather than a specific pathogenic organism, the inflammatory process is likely to relate at least in part to an interaction between intestinal flora and the mucosa (Macpherson et al, 1996), (Martin et al, 2000), (Leiper et al, 2001).

The chemokine subset described dominates the total mucosal response in moderate to severe colitis, with expression stronger in colon biopsies from the UC than CD cohort, at similar degrees of mucosal inflammation. The concordance with inflammation was particularly notable for UC, with non-inflamed areas correlating with non-inflamed controls. Chemokine expression was independent of the anatomical origin of colonic biopsies, with array values statistically correlating between anatomical sites within normal control patients. Expression levels were higher in full thickness CD samples than CD biopsies, suggesting origin in deeper layers. Statistical analysis of RT-PCR data from full thickness IBD samples did not indicate a significant up regulation in CXCL's 1-3, CXCL8 and CCL20. This may well relate to drug treatment; the patients in the IBD biopsy cohort underwent colonoscopic examination for screening purposes, where the majority of patients in the surgical resection cohort had more active disease, and were almost all on some form of immunosuppressive agent. In the biopsy cohort, 1/8 UC and 2/6 CD patients were on immunosuppressive therapy, compared to 6/6 UC and 6/9 CD in the full thickness cohort (appendix 2.3 and 4.4). This presents a recruitment challenge for further similar research projects of this nature involving full thickness colonic samples in IBD cohorts if all patients on immunosuppressive therapy are to be excluded.

Analysis of inflamed full thickness sections taken from a single diverticulitis patient also demonstrates expression of the same chemokine subset, while colon biopsies from two infectious colitis patients were inconclusive given the low histopathological scoring for inflammation. Study of larger numbers of patients of defined genotype will be required both to determine whether subgroups of patients with CD may show similar elevation of these chemokines, and also to determine whether or not the coordinated chemokine expression pattern can be distinguished from that of non-IBD patients with acute colitis. It is likely that the coordinated chemokine response described will be invoked transiently in infectious colitis, and

further studies will be required to elucidate the role of this response in other mucosal inflammatory states.

These findings are compatible with other published data. In an early microarray analysis of three specimens of CD mucosa, CXCL3 was found to be elevated (Heller et al, 1997), and analysis of a small number of full thickness IBD and normal colon specimens indicates up regulation of CCL20 expression in CD but not UC (Kwon et al, 2002). Banks et al (2003) demonstrated up regulated chemokine expression correlated with disease activity, suggesting that the degree of tissue damage in IBD is dependent on the local expression of specific chemokines within IBD tissue. Previous research has also demonstrated that chemokines secreted by epithelial cells directly regulate the inflammatory intestinal response (Ohtsuka et al, 2001).

CCL20 up regulation is of particular importance, as this chemokine is specifically involved in mucosal immunity, especially in the human intestinal epithelium, where it induces local migration of dendritic cell subsets expressing the receptor CCR6 (Liao et al, 1999), (Dieu-Nosjean et al, 2000), (Nakayama et al, 2001), (Kwon et al, 2002), (Kaser et al, 2004). Presented data for epithelial expression of CCL20 have been collated from several different experimental modalities, including microarray, immunohistochemistry and flow cytometry. CCL20 is widely expressed by human intestinal epithelium, particularly in Peyer's patches, and the findings are compatible with this chemokine being a vital constituent of epithelial immunity. The absence of dendritic cells in Peyer's' patches in CCR6-deficient mice implicates a central role of CCL20 in the regulation of organised mucosa-associated lymphoid tissue (MALT) (Cook et al, 2000).

Immunohistochemical staining undertaken within this research demonstrates stronger CCL20 and CCR6 epithelial staining in IBD samples compared to controls. Furthermore, there are differential patterns of cellular density and locality within the lamina propria. For CCR6, in addition to the subepithelial locality seen in controls, $CCR6^{+}$ cells extend deep into the lamina propria in IBD cases. Conversely, $CC20^{+}$ cells are notable in the same subepithelial area as controls, although in greater numbers. This may well be crucial to dendritic cell activation during inflammation. While infiltrating leukocytes will contribute to the total chemokine response, undoubtedly including members of this coordinate response, the very modest up regulation of other known leukocyte chemokines seen in active UC suggests that a major contribution to the mucosal response is likely to be epithelial. Such epithelial dominance is consistent with the concept that epithelial activation may be a central determinant of colonic inflammation (Fiocchi et al, 1997), (Shao et al, 2001). Chemokine up regulation in epidermal cells occurs in response to external assault, and is thought to relate to an attempt to counteract potential antigenic invasion during the period of impaired barrier function, which is, not surprisingly, concordant with the proposed intestinal mucosal mechanism (Schmuth et al, 2002).

After binding of CCL20 to dendritic cells, the expression of CCR6 is down regulated, and CCR7 is up regulated. The change in expression levels of CCR6 and CCR7 contributes to the functional changes that are characteristic of dendritic maturation (Dieu et al 1998). Within the specific chemokine cluster identified, several UC samples also exhibited expression of the

CCR7-binding chemokines, CCL19 and CCL21, and the CXCR5 binding chemokine, CXCL13. CCR7 is a chemokine receptor of pivotal immunological importance, as it enables antigen-loaded mature dendritic cells to be guided into draining T cell-rich areas of lymph nodes by CCL19 and CCL21 (Nakayama et al, 2001), (Caux et al, 2002). These antigen-presenting cells are crucial for the initiation, continuation and regulation of an immunological response, activating naïve T and B cells, which subsequently return to the site of inflammation. After taking up antigen, dendritic cells become unresponsive to inflammatory chemokines and concomitantly acquire CCR7 expression. Maturing dendritic cells enter the lymph stream under the guidance of CCL19 and CCL21, which are expressed on lymphatic vessels (Caux et al, 2002), (Cravens et al, 2002). They therefore leave the inflamed tissue and enter draining lymph nodes. Concomitantly, CCR7-expressing naïve T cells enter lymph nodes in response to the production of CCL21 by HEVs, located primarily in the T-zone. Few HEV segments pass through the B-zones in lymph nodes (Campbell et al, 2003). CCR7 ligands are widely distributed in T-zone. Furthermore, the newly arriving dendritic cells may themselves be sources of CCL19 and CCL21, thus facilitating further amplification. Most of these pathways are uncharacterised, and the published data vary. However, the fact that these two chemokines can attract both dendritic cells and lymphocytes clearly implicates their role in the essential encounter between antigen-loaded dendritic cells and antigen-specific T cells. In mice lacking these two chemokines, or with B cells that lack CCR7, antigen engagement fails to cause movement to the T zone (Reif et al, 2002). There seems to be a carefully maintained chemokine balance within the lymphoid zones to facilitate appropriate cellular positioning within these two separate but adjacent zones. Following this encounter, dendritic cells produce many chemokines facilitating $CD4^+$ T cell interaction with $CD8^+$ T cells and B cells (Caux et al, 2002). Dendritic cells are also crucial to tolerisation (McColl et al, 2002). One possible pathogenic mechanism in IBD is a lack of T cell tolerisation which could lead to an over-active immune response with CCR7/CCL21/CCL19 potentially central to the ensuing inflammatory response.

As homeostatic trafficking of B and T lymphocytes and dendritic cells into secondary lymphoid tissue is predominantly mediated by CCL19 and CCL21, and organised lymphoid aggregates in the deep lamina propria are characteristic of UC, expression of these three chemokines presumably indicates the presence of lymphoid tissue within these particular biopsies (Yeung et al, 2000). However, this cannot be confirmed as histology was performed on adjacent biopsies.

CCR6 may well be pivotal for entry into lymphoid tissue, via HEV's. It is interesting to note that within lymphoid tissue, $CCR6^+$ immunoreactive cells are primarily limited to T cell areas. This is consistent with other research that has demonstrated CCR6 to be absent from germinal centre B cells of secondary lymphoid organs, although it is present in bone marrow- and peripheral blood-derived naïve and /or memory B cells (Krzysiek et al, 2000). CCR6 is down regulated following B cell antigen triggering, and is only up regulated after the clonal expansion into immunoglobulin -secreting plasma cells, at the post-germinal centre memory cell stage (Krzysiek et al, 2000). Thus, CCR6 is essentially restricted within the B cell compartment to B cells capable of antigenic challenge. Restricted CCR6 expression is likely to be central to the B cell maturation process.

Immunohistochemical staining of CXCR1 and CXCR2 demonstrates a clear upwards extension of immunoreactive cells towards the epithelium in IBD compared to controls, although there is no significant change in epithelial immunoreactivity. Although this cellular distribution has not yet been fully characterised, cellular positioning within the mucosa is likely to be of importance. *In vitro* studies using epithelial cell lines have demonstrated the capacity of lymphocyte and macrophage derived peptide factors to induce intestinal epithelial cell restitution (Mahida et al, 1997). Furthermore, following removal of surface epithelium, large numbers of lymphocytes, macrophages and eosinophils migrate out of the intestinal lamina propria. The migration occurs via tunnels in the extracellular matrix and is likely to be part of the host defence elicited following epithelial injury (McAlindon et al, 1998). The increased density of CCL20-, CXCR1- and CXCR2-staining cells in the subepithelial lamina propria is consistent with this, and chemokines are likely to direct the repositioning of cells during such inflammation.

The receptors CXCR1 and CXCR2 in conjunction with two of their cognate chemokines CXCL1 and CXCL8, are thought to account for the initial destructive changes seen in UC, with a neutrophilic infiltration into the epithelium (Williams et al, 2000). CXCR2 is also the receptor for CXCL2 and CXCL3 (Zlotnik et al, 2000). CXCL8 is known to attract neutrophils, macrophages and T lymphocytes and may well be pivotal in IBD inflammation. It activates CXCR1 and CXCR2 on microvascular endothelial cells using different signal transduction, which may contribute to the increased vascular permeability and leukocyte adhesiveness observed in acute inflammation (Schraufstatter et al, 2001). The precise role of CXCL8 is yet to be ascertained; although CXCL8 has previously been shown to be elevated in IBD tissue, with elevated levels also in quiescent IBD compared to control (Banks et al, 2003). This is not substantiated by the results from this thesis, which indicate that non-inflamed UC tissue has the same chemokine expression generally as control tissue. Up regulation in CD tissue did not however correlate with inflammation.

In previous research, CXCL8 levels have been found in *Helicobacter pylori* mediated gastritis in association with CXCL5, CXCL8, CXCL10 and CXCL13. Furthermore, an increased expression of CXCL8 and CCL3 was found in association with peptic ulceration. Eradication of *Helicobacter pylori* was demonstrated to reduce such chemokine expression (Ajuebor et al, 2002)[2]. The role for CXCL8 in the intestine is therefore not limited to the colon.

A further notable result from the research presented is increased expression of CCL5 and CCR5 in full thickness CD tissue that did not correlate with inflammation. However, colonic epithelial cell culture study did not indicate an induction of CCL5 following stimulation with pro-inflammatory cytokines. Qin et al (1997) suggested that CCR5 marks subsets of lymphocytes with a capacity for migration to inflammatory sites, or else that CCR5 is induced following inflammatory cytokine stimulation. Although this thesis does support the latter, other published data indicate up regulation of CCR5 by IL-2 (Baggioloni et al, 1998), which was not tested in this research, but may be a valuable experiment for future investigative study. The elevated levels of CCR5 and CCL5 in full thickness CD tissue remains uncharacterised, but these results are consistent with previous suggestions that CD is a Th1 disease, as CCR5 is expressed primarily

by Th1 cells (Baggioloni et al, 1998), (Sallusto et al, 1998)[1], (Monteleone et al, 2002). CCR5 is also expressed by immature dendritic cells (Sallusto et al, 1998)[2]. Several years ago, the second extracellular loop of CCR5 was identified as an ideal target for the development of inhibitors, as the chemokine pattern of binding is relatively simple. Furthermore, CCR5 functions as the principal co receptor for macrophage strains of HIV-1 (Wu et al, 1997).

Previously, it has been shown that CCL20 can be up regulated by stimulation by pro-inflammatory cytokines (Izadpanah et al, 2001). Furthermore, colonic epithelial cells freshly isolated from IBD patients and normal controls show strong expression of receptors for IL-1β but not TNF-α, and respond only to IL-1β. Cell culture results presented here is confirmatory of this. Data from stimulated gut-derived Caco-2 cells demonstrate that IL-1β up regulates CXCL's 1-3, CXCL8 and CCL20, while both IL-1β and TNF-α induce expression from HT-29 cells. Previous research has indicated that both IL-1β and TNF-α together are required to induce this group of chemokines in epithelial cells derived from the skin. This group substantially dominates the epithelial response by orders of magnitude over any other chemokines. In addition, the anti-inflammatory chemokine CXCL10 was induced in Caco-2 cells following pro-inflammatory stimulation with IL-1β and to a lesser extent TNF-α. IL-1β and TNF-α together led to a cumulative induction, which is consistent with published data (Parekh et al, 1999).

Results from cultured epithelial cell line chemokine response have to be interpreted with some caution, as Caco-2 cells are not always predictive for the response *in vivo*. They are differentiated tumour cells, which do not entirely respond as intestinal epithelial cells do. Experimentation using cell culture lines is complicated by the dynamic nature in cellular maturation in surface villous epithelial cells. The migration from the crypt base to the surface of the colon is accompanied by cellular differentiation that leads to important morphological and functional changes. Cellular differentiation of HT29 cells selectively impairs the IL-1β signalling pathway inhibiting NF-κB activity in response to IL-1β. This may result from an increased expression of the decoy IL-1RII, which does not transduce signal. Published research indicates that LPS- and IL-1β-induced CXCL8 secretion are impaired in differentiated cells which is contrary to the findings from this research, where CXCL8 levels were induced by IL-1β. Other published data indicate there is loss of IL-1β induced CXCL8 production in both HT-29 and Caco-2 cells on differentiation towards a small intestinal phenotype (Huang et al, 1997), (Bocker et al, 2000). To optimise the conditions of the cultured Caco-2 and HT29 cell lines, the cells were harvested just post-confluence, when they retain colonic phenotype rather than small intestinal (Engle et al, 1998) and appear to represent a physiologically relevant model of human colonocytes in respect of TNF-α and IL-1β responses (Fujiie et al, 2001), (Yang et al, 1997). This relative unresponsiveness to IL-1β following cellular differentiation may represent an important regulatory mechanism of differentiated intestinal epithelial cells (Bocker et al, 2000). TNF-α mediated NF-κB activity is unaffected by cellular differentiation. Although TNF-α and IL-1β transduce many of their shared pro-inflammatory responses through a common pathway of NF-κB induction, there are differences in their proximal signal pathways. There is also evidence from monocyte lines that they use differential regulatory steps in IκB kinase induction and IκBα

degradation (Nashuhara et al, 1999), (Hong et al, 2001). Further analysis of the differential response to IL-1β and TNF-α in gut-derived cell lines may give insight into the signalling pathways that differentiate colonic from small bowel IBD. In this initial investigative study, the cell lines included do provide initial valuable evidence that provide a basis for further primary epithelial study.

The transcription factor NF-κB is of great importance in the gastrointestinal tract, being a key regulator of gene expression involved with gastrointestinal immunity and inflammation. It regulates chemokines including CCL20, acute phase proteins, cytokines and growth factors in the inflamed mucosa of IBD patients (Fujie et al, 2001), (Izadapanah et al, 2001), and is essential for cell growth, oncogenesis and escape from apoptosis (Dhawan et al, 2002). Once released from an inactive cytoplasmic complex, NF-κB dimers translocate to the nucleus and bind to specific sequences to promote transcription (Dijkastra et al, 2002). Many of the drugs utilised for IBD are beneficial in part from their inhibition of NF-κB, such as mesalazine and steroids. Mesalasine prevents the IL-1 induced phosphorylation of the p65 subunit of NF-κB. Steroids maintain the NF-κB in the inactive cytoplasmic form (Dijkastra et al, 2002). IL-10 also inhibits NF-κB activation. Dysregulation of this transcription factor leads to constitutive expression of chemokines and cytokines. Several other cofactors and repressors are involved in chemokine regulation such as PARP. Identification of specific NF-κB inhibitors may be of great therapeutic benefit. The Caco-2 cell culture data presented indicates that TSA enhanced CCL20 production two-fold in conjunction with IL-1β, and fully inhibited IL-1β induction of CXCL10. This is consistent with a TSA distinct pathway of induction via reduction of histone deacetylase co-repressor proteins. Since acetylation of the histone tail induces transcription through chromatin remodelling, a reduction in deacetylation promotes chemokine production. Specific inhibitors of NF-κB may well be of therapeutic benefit in many diseases including IBD. Selective agents such as antisense p65 are likely to be more effective and less toxic that current therapeutic agents.

Primary epithelial cell culture is a more appropriate model than colonic carcinoma cell lines, and further research in this area is warranted. The pilot primary epithelial cell culture study yielded interesting results, with induction of CXCL' s1-3, CXCL8 and CCL20 following stimulation with IL-1β or TNF-α, which is concordant with other published data (Kwon et al, 2002). Kwon et al also found that colonic epithelial cells are an important source of CCL20 and postulated that increased production may be important in recruitment of $CD4^+$ T lymphocytes and immature dendritic cells to the epithelial layer in IBD. However, the greatest value of this small study was in establishing the viability of primary colonic cell culture in this manner, and further research is required.

Immunostaining of NEC sections for CCL20 and CCR6 illustrates the potential application of this technique to other diseases apart from IBD. Perineural T cell infiltration, glial disruption and $CCL20^+$ infiltration into the myenteric plexus have been demonstrated. Delineation of cause and effect is not possible from this research, although as CCL20 becomes increasingly characterised with time, its relevance in NEC should become more apparent. Furthermore, this provides a

potential target for therapeutic intervention, for example via CCR6 blockade. Furthermore, immunohistochemical examination of myenteric infiltration with CCL20/CCR6^{+} cells in IBD patients would be a valuable study. Double immunostaining of full thickness intestinal sections for CCL20 and CCR6 would probably yield interesting results and may help characterise these pathways. This was infact attempted towards the end of the research period, although as the CCR6 antibody was a mouse antibody species and the CCL20 a goat antibody species, results were unsatisfactory and further work is required. A primary entero-neural pathological process is unlikely to be causal of IBD, but may explain the associated dysmotility (Vrees et al, 2002). Previous research has established that enteric glia play an essential role in maintaining the integrity of the bowel, and their loss or dysfunction may contribute to the cellular mechanisms of IBD (Bush et al, 1998), (Bush, 2002). Disruption of the enteric glial network has also been hypothesised to contribute to the enhanced mucosal permeability and vascular dysfunction in IBD (Cabarrocas et al, 2003). IL-1β has been shown to suppress enteric glial proliferation and enhance further pro-inflammatory cytokine production (Cabarrocas et al, 2003). These glial cells therefore are clearly able to respond to inflammatory stimuli.

As chemokines and pro-inflammatory cytokines determine the intensity of the inflammatory response, therapeutic inhibition of the coordinate epithelial chemokine response is likely to provide significant clinical benefit in UC. Although manipulation of chemokine expression for therapeutic benefit has been accomplished for years with corticosteroids, cyclosporin A, etc., the production of more specific agents acting at individual cytokine levels remains an attractive and increasingly plausible option in the treatment of chronic inflammatory disorders.

The focal expression of CCL20 makes its interaction with CCR6 an attractive target for therapy, as this is unlikely to affect systemic immune responses. A further feature of the CCR6 receptor that makes it an ideal potential therapeutic target is the lack of promiscuity, with binding only to two ligands; CCL20 and β-defensin (Yeung et al, 2000). Blockade of this receptor may well be an effective and specific agent with minimal toxicity, not only in IBD but in other inflammatory epithelial conditions. Other possible targets include CCR5 in CD, which has previously been identified as potential target in other diseases including MS (Balashov et al, 1999).

The data presented here suggest that therapeutic inhibition of the interaction between IL-1β and colonic epithelium may remove one of the pro-inflammatory drivers in moderate/severe UC. Effective IL-1β inhibitory therapy may mediate a specific and effective anti-inflammatory response in UC. The evidence that different intestinal epithelial lines have distinct responses to IL-1β and TNF-α in the induction of members of this coordinate chemokine response suggests that IL-1β may be an important therapeutic target in its own right, particularly in UC (Bocker et al, 2000), (Fujiie et al, 2001), (Wen et al, 2001).

Multiple independent lines of evidence support the pivotal role of IL-1β: IL-1 receptor antagonist therapy is extremely effective in experimental colitis in rabbits (Cominelli et al, 1990), mice with targeted deletion of IL-1β converting enzyme are highly protected from colitis (Siegmund et al, 2001), polymorphism of both the IL-1β promoter and IL-1 receptor antagonist are associated

with IBD and may influence severity (Nemetz et al, 1999), (Carter et al, 2001), and significant reduction of the IL-1 receptor antagonist: IL-1 ratio occurs in active disease (Andus et al, 1997). Cominelli's study demonstrated that administration of the antagonist decreases IL-1 levels; specific blockade of IL-1 receptors reduces the inflammatory responses associated with experimental colitis (Cominelli et al, 1990). IL-1 gene expression and synthesis occur early in the course of immune complex-induced colitis, with tissue levels of IL-1 correlating with the degree of tissue inflammation.

Reducing the biological activities of IL-1 and TNF may be accomplished by several different, but highly specific strategies, including neutralising antibodies, soluble receptors, receptor antagonist, and inhibitors of proteases that convert inactive precursors to active, mature molecules. Blocking IL-1 and TNF has been highly successful in patients with rheumatoid arthritis and graft-versus-host disease but has not been successful in humans with sepsis (Deon et al, 2001). Clearly TNF-α is an important therapeutic target in CD, as TNF-α monoclonal antibodies have induced substantial clinical responses in previously resistant disease (Baert et al, 1999). Inhibition of IL-1β-converting enzyme (ICE) is a further anti-inflammatory strategy for IBD as it is a key contributor in intestinal inflammation. This enzyme is the intracellular protease that cleaves the precursors of IL-1β and IL-18 into active cytokines. Its naturally occurring inhibitor, IL-1Ra maintains an effective balance. Mice deficient in IL-1Ra develop spontaneous rheumatoid arthritis and lethal arteritis, but IL-1Ra administration reduces disease severity.

8.2 Conclusions

These data identify a previously unrecognised coordinated epithelial chemokine response in active IBD, including CXCL's 1-3, CXCL8 and CCL20. IL-1β appears to be the pivotal mediator of an epithelial response that dominates the chemokine environment in UC. Several new therapeutic targets have been identified that may well enable new specific non-toxic agents to be developed in the treatment of active IBD. The focal expression of CCL20 makes its interaction with CCR6 an attractive target for therapy, as this is unlikely to affect systemic immune responses. IL-1 receptor antagonism is also of potential therapeutic benefit in IBD.

Furthermore, the use of microarray hybridisation has been applied to IBD. DNA Microarray analysis represents one of the major recent advances in functional genomics, enabling the study of many genes within an investigative clinical setting.
