1 Abstract

- 2
- 3

4	Previous research on young children's knowledge of prosodic focus marking has
5	revealed an apparent paradox, with comprehension appearing to lag behind
6	production. Comprehension of prosodic focus is difficult to study experimentally due
7	to its subtle and ambiguous contribution to pragmatic meaning. We designed a novel
8	comprehension task, which revealed that 3-6-year-old children show adult-like
9	comprehension of the prosodic marking of subject and object focus. Our findings thus
10	support the view that production does not precede comprehension in the acquisition of
11	focus. We tested participants speaking English, German and French. All three
12	languages allow prosodic subject and object focus marking, but use additional
13	syntactic marking to varying degrees (English: dispreferred; German: possible;
14	French preferred). French participants produced fewer subject marked responses than
15	English participants. We found no other cross-linguistic differences. Participants
16	interpreted prosodic focus marking similarly and in an adult-like fashion in all three
17	languages.
18	

19 Keywords:

20 Focus, acquisition of focus, production before comprehension paradox, prosodic

21 focus marking, cross-linguistic comparative acquisition, correction task

1 Introduction

2

Focus in natural language has an important communicative function: it indicates to
the hearer what the speaker intends to assert. For successful communication, children
need to learn to correctly identify, comprehend and produce utterances with focus.

6

7 Previous research on how young children comprehend and produce focus has revealed 8 an apparent paradox. Children as young as 2-3 years of age appear to produce 9 prosodically marked focus correctly (Baltaxe, 1984; Furrow, 1984; Hornby & Hass, 10 1970; Wieman, 1976), but they do not seem to comprehend it in an adult-like manner 11 before 6 years of age (Gualmini, Maciukaite, & Crain, 2003; Hornby, 1971; Paterson, 12 Liversedge, Rowland, & Filik, 2003; Szendrői, 2004). Does focus constitute a 13 genuine case in language development whereby comprehension lags behind 14 production? Or can children's failure to understand prosodically marked focus in an 15 adult-like fashion early in language development be attributed to task-effects or 16 language-external cognitive limitations? The purpose of the current study is to address this question, suggesting that with appropriately designed experimental tasks, children 17 18 can show adult-like focus comprehension early on.

19

20 Focus marking in the world's languages

21

The focus of an utterance may be identified using the *wh*-question test: the part of the utterance that responds to the question is in focus (Chomsky, 1971). For example, in (1a), the focus is on the subject and in (1b), it is on the object. Across languages, there is variation with respect to the linguistic means that mark information structure. While

1	in sor	ne lang	uages intonation may be the major device, in others	syntactic means like	
2	word order variation or morphological markers may be more important (see e.g.				
3	Vallduvi & Engdahl, 1996). In English, the focal part of an utterance bears prosodic				
4	prom	inence.	(Capital letters indicate main stress throughout the p	aper.)	
5					
6	(1)	a.	Subject focus:	ENGLISH	
7			Q: Who has the bottle?		
8			A: The BIRDIE has the bottle.		
9		b.	Object focus:		
10			Q: What does the birdie have?		
11			A: The birdie has the BOTTLE.		
12					
13	Giver	n its inf	ormation structural highlighting function, it is not su	rprising that focus is	
14	often	(or per	haps always) marked prosodically in many languag	ges including English	
15	(1), 6	German	(2) and French (3).		
16					
17	(2)	a.	Subject focus:	GERMAN	
18			Der VOGEL hat die Flasche.		
19			the bird has the bottle		
20			The BIRD has the bottle.		
21		b.	Object focus:		
22			Der Vogel hat die FLASCHE.		
23			the bird has the bottle		
24			'The bird has the BOTTLE.'		
25					

1	(3)	a.	Subject focus:	FRENCH
2			L'OISEAU a la bouteille.	
3			the bird has the bottle	
4			The BIRD has the bottle.	
5		b.	Object focus:	
6			L'oiseau a la BOUTEILLE.	
7			the bird has the bottle	
8			'The bird has the BOTTLE.'	
9				

10 Furthermore, there is a theoretical asymmetry (Reinhart, 2004) between utterances 11 with subject focus, like (1a) and utterances with object focus, like (1b). The neutral 12 position of prosodic prominence in sentences like (1-3) is believed to be on the object 13 in these languages (Reinhart, 2004; Cinque, 1993). The subject can get prominence by 14 an extra prosodic operation, stress shift. One important consequence of this account is that object focus utterances are default, as they represent neutral prosody, while 15 16 subject focus utterances are marked. Given this asymmetry, it is potentially possible 17 that speakers treat utterances with stress shift on the subject and utterances with 18 neutral, object stress differently.

19

At the same time, even though all three languages have default main stress on the object, they differ in how much flexibility they have in deviating from this default (Vallduví 1992, Vallduví & Engdahl 1996). English is highly flexible, because in this language stress shifting and marked pitch accent to the focal constituent can target essentially any constituent. In French, subject focus marked by shifting prosodic prominence to the subject is possible (3a), as in English, but the preferred method is

1	to use a specific syntactic construction, the cleft (4) (Hamlaoui, 2008, 2009;
2	Lambrecht, 1994).
3	
4	(4) C'est l'OISEAU qui a la bouteille. FRENCH
5	it is the bird who has the bottle
6	'The BIRDIE has the bottle'
7	
8	German primarily uses prosody like English (2a). However, in addition to stress shift
9	syntactic operations, e.g. change in word order are also available (5) . ¹
10	
11	(5) Die FLASCHE hat der Vogel. GERMAN
12	the bottle has the bird
13	'The bird has the BOTTLE.'
14	
15	Given such cross-linguistic differences, it is possible that prosodic focus marking is
16	processed differently and acquired at a different rate in different languages. It could
17	be that in English, children acquire prosodic focus marking earlier, especially in the
18	case of shifted stress, than in French, where there is greater variation due to the
19	prosodic accent shift option being only one of the options used by adults (Beyssade,

20 Hemforth, Marandin, & Portes, 2009). The behaviour of German children is expected

¹ Sentence initial focus has a special pragmatic import in German, expressing contrast. But contrast need not be expressed by sentence-initial accent, it is merely an option to do so. In this paper we are concerned with prosodic focus placement and leave word order variations associated with focus for future research.

to be more similar to that of English children, given that German also allows stress
shift freely.²

3

4 Apart from cross-linguistic differences regarding the use of prosodic focus marking, 5 there are two further important points to note. First, prosodic focus marking is not a 6 stable cue. Phonetically, a wide range of pitch movements can be used for focus 7 marking by different speakers in different contexts. Partly this is because prosodic 8 focus marking interacts with other aspects of intonational marking, such as clause-9 typing (e.g. declarative), givenness marking (i.e. deaccentuation of constituents that 10 are accessible in the discourse context). It is also subject to a high degree of phonetic 11 variation due to speaker variation, speech rate etc. Second, prosodic accents do not 12 exclusively mark focus. They may have other functions, such as expressing emotional 13 attitude of the speaker (e.g. surprise or disapproval: The birdie has the BOTTLE ?!). 14 Which means that the hearer has different options when trying to interpret prosodic 15 accent: it could mark the focus or the speaker could have used it to signal their 16 emotional attitude or other pragmatic functions.

17

Perhaps unsurprisingly, given its ambiguous nature, in real-life discourse, prosodic focus marking is often a near-superfluous information structural cue. The focused constituent of a particular utterance is often predictable with a high probability from the preceding discourse. This is why it is mostly unnecessary to indicate focal prosody in writing: when reading a text, we can predict the correct accent placement

² In future studies, it would make sense to investigate any potential effect of the availability of non-neutral word order in German, in addition to the availability of stress shift.

1 from the discourse context and from the grammatical structure of the sentence. 2 Consequently, listeners are hardly ever confronted with a discourse situation where 3 their only cue to identify the focus of the utterance would be prosodic focus marking. 4 For this reason, in any study where participants have to rely only on this subtle 5 prosodic cue to determine the correct response, we can expect a relatively small 6 effect. But prosodic focus marking is crucial for successful communication in 7 precisely those situations where the focus of the utterance is not the only possible one 8 given previous discourse.

- 9
- 10

11 **The acquisition of focus**

12

13 Given the ambiguous nature of prosodic focus marking, it is perhaps not surprising 14 that previous findings on its acquisition show a seemingly paradoxical behaviour: 15 children have been found to produce prosodic focus marking correctly at least in 16 certain pragmatic contexts as young as 2 years (Furrow, 1984 and Wieman, 1976 for 17 spontaneous speech; Hornby & Hass, 1970 for a picture description task; Baltaxe, 18 1984 for elicited production), while they seem to find it problematic to interpret focal 19 accent in an adult-like manner (again, at least in certain contexts) at least until the age 20 of 6 (Lahey, 1974 for an act-out task; Bates, 1976 for an imitation task; Paterson, 21 Liversedge, Rowland, & Filik, 2003 for a picture selection task with children up to 12 22 years; Gualmini et al., 2003, Szendrői, 2004 for truth-value judgment tasks). In fact, 23 Hornby (1971) found that the very same children who showed good production, had 24 comprehension problems.

As far as production is concerned, the available literature is largely based on 1 2 spontaneous data. It is hard to design an elicitation task, as children often answer 3 elicitation questions with a single-constituent reply. A. Chen (2010) employed a 4 robot, which presented the answer in an abnormal prosody constructed from a 5 randomised word list read by a native speaker. The children were instructed to 'reconstruct the robot's answer in his/her intonation'. A. Chen found that both 6 7 children and adults accented focal constituents (both subjects and objects) in over 8 90% of the cases. However, she also found that the non-focal, given constituent was 9 also often accented both by children and adults, and at least in the sentence-final 10 position, more so by children. She interpreted this as evidence of partial competence 11 of focus marking. In our interpretation, the fact that children almost always accented 12 the focal constituent is evidence of full competence of prosodic focus marking. Adults 13 can appropriately apply deaccenting to the sentence-final, given constituent, but 14 children have difficulties doing so, ending up with a correctly placed focal accent and 15 an additional incorrect default accent on the sentence-final constituent. There are at 16 least two possible explanations that may account for why children show such over-17 accentuation. First, it is possible that they cannot successfully over-ride default accent 18 placement in the sentence-final position due to inhibition problems, which are widely 19 documented to influence pre-schoolers' linguistic abilities (Hamburger & Crain, 1984; 20 Trueswell, Sekerina, Hill & Logrip, 1998). Second, it is possible that children have 21 not yet fully acquired givenness marking. There are other studies reporting deficient 22 competence with respect to givenness marking in children (e.g. Schaeffer & Matthewson, 2005; De Cat, 2009).³ Using a method similar to A. Chen's, Müller, 23

³ Interestingly, the divergent acquisition evidence in terms of focus marking and givenness marking, i.e. that children show early competence with the former but not

Höhle, Schmitz and Weissenborn (2009) provided evidence that German 4-to-5-year olds marked focus with a high pitch independently of the grammatical role and the sentence position of the constituent, further supporting our interpretation that the production of focus competence is in place by this age. We conclude then that A. Chen's production findings are thus consistent with the possibility that children are in fact fully competent with prosodic focus marking.

7

8 In comprehension, much of the previous research involved explicit judgment tasks 9 (Paterson et al., 2003; Szendrői, 2004). But there is reason to believe that the nature of 10 these tasks may have influenced the results. Explicit judgment tasks come in two 11 types. The first type involves the truth-value judgment task. For instance, Szendrői 12 (2004) compared sentences like (6a) and (6b) with focal stress on the indirect object 13 and the direct object, respectively. Such sentences are true and false in different 14 situations: (6a) is true if Tigger did not throw a chair to any other creature apart from 15 Piglet, and it is false if Tigger also threw a chair to another creature, say Winnie the 16 Pooh. In contrast, (6b) is true if Tigger did not throw any other object to Piglet apart 17 from a chair, and false if Tigger also threw another object, say a table to Piglet.

18

19 (6) a. Tigger only threw a chair to PIGLET.

- 20 b. Tigger only threw a CHAIR to Piglet.
- 21

Crucially, this truth-conditional difference is due to the presence of *only* in the test
 sentences. To see this, compare the sentences in (6) with their minimal pairs without
 the latter, pose a serious empirical problem for theories of focus that treat the two as two sides of the same coin (e.g. Wagner, 2012).

1	only in (7) in the two situations described above. Both (7a) and (7b) are semantically
2	true so long as Tigger threw a chair to Piglet, irrespective of what other events may or
3	may not have taken place. So, in contrast to (6a), (7a) is not false in a situation where
4	Tigger threw a chair to Piglet and also to Winnie the Pooh. It is pragmatically
5	inappropriate to place marked focal stress on the indirect object, Piglet, in such a
6	situation. But this does not make the utterance semantically false in this situation.
7	Similarly, (7b) is not false in a situation where Tigger threw a chair and also a table to
8	Piglet. It is, again, pragmatically inappropriate (in other words infelicitous) to use
9	marked focal stress on the direct object chair, but not semantically false.
10	
11	(7) a. Tigger threw a chair to PIGLET.
12	b. Tigger threw a CHAIR to Piglet.
13	
14	For this reason, judgment tasks relying on a different truth-value between the
15	utterances with different focal stress placement always involve a semantic operator,
16	such as only, which ensures that the pragmatic difference between the utterances
17	involving different prosodic foci is augmented to a semantic difference affecting
18	truth-conditions (see also Hüttner, Drenhaus, van der Vijver, & Weissenborn, 2004;
19	Zhou, Su, Crain, Gao, & Zhan, 2012 for similar studies). This is potentially
20	problematic because such tasks therefore also test children's ability to comprehend
21	such operators, which may influence the results.

22

The second type of explicit judgment task taps directly into the pragmatic (in)felicity
of the different focal stress placements in certain discourse situations. For instance, A.
Chen (2010) relies on the fact, already illustrated above in (1), that in question-answer

1	pairs	, focal	stress p	lacement in the answer is determined by the wh-constituent. In
2	particular, the declarative utterances in (8a) and (8b) are pragmatically inappropriate			
3	respo	onses to	the que	stions provided because their foci do not match the wh-element of
4	the co	orrespo	nding qu	uestions. (Pragmatic infelicity is marked by #.)
5				
6	(8)	a.	Q:	Who did Tigger throw a chair to?
7			A:	#Tigger threw a CHAIR to Piglet.
8		b.	Q:	What did Tigger throw to Piglet?

#Tigger threw a chair to PIGLET.

10

9

A:

11 In accordance with this, A. Chen (2010) asked participants to determine whether a 12 character gives a correct answer to another character's question in a dialogue that the 13 child hears. But, contrary to her expectations, both children and adult participants 14 interpreted answers that were pragmatically infelicitous, but semantically truthful as 15 correct. It is nevertheless possible that children, and especially adults, are able to 16 determine the focus based on accentual information, but they do not consider the 17 inappropriate focus placement a strong enough reason to judge the question-answer 18 pair as incorrect. After all, it is possible to interpret correctness as simply providing 19 an answer that is semantically truthful. Chierchia, Crain, Guasti, Gualmini, and 20 Meroni (2001), Gualmini, Crain, Meroni, Chierchia, and Guasti (2001) and 21 Papafragou and Musolino (2003) make similar observations in other areas of the 22 semantics-pragmatics interface in children.

23

This interpretation of the results might be supported by the fact that in A. Chen's comprehension task children had a significantly longer reaction time judging

1 pragmatically infelicitous question-answer pairs, suggesting that they were aware of 2 the inappropriate focal accent placement of such declarative utterances in the context. 3 Similarly, implicit measures, in this case eye fixation patterns indicated sensitivity to 4 focal accent placement in a study involving children's interpretation of sentences with 5 the German particle auch 'too' (Höhle, Berger, Müller, Schmitz, & Weissenborn, 6 2009), while explicit picture selection was non-adultlike (Hüttner et al., 2004). Zhou 7 et al. (2012) also found delayed but adult-like patterns in a visual-world eye tracking 8 task involving Mandarin-speaking children using the operator *zhiyou* 'only', but non-9 adult-like explicit judgments. Höhle et al. attribute the variation in children's 10 performance in different tasks to different constraints the tasks place on the 11 manifestation of the underlying knowledge, while Zhou et al. argue that the prosody-12 pragmatics connection is less developed in children compared to adults.

13

14 Note that it is also unlikely that the comprehension problems reported in the literature 15 would be the result of perceptual problems related to pitch or prosodic processing, 16 given the range of evidence suggesting that even infants are highly sensitive to 17 prosodic information, such as pitch and lexical stress patterns (e.g. Höhle, Bijeljac-18 Babic, Herold, Weisenborn & Nazzi, 2009; Sansavini, Bertoncini & Giovanelli, 1997) 19 or prosodic phrasing (Gervain & Werker, 2013; Nazzi, Kemler Nelson, Jusczyk, & 20 Jusczyk, 2000; Wellmann, Holzgrefe, Truckenbrodt, Wartenburger, & Höhle, 2012). 21 Further, focal accent is highly conspicuous in infant-directed speech, as it coincides 22 with the pitch peak of the sentence, unlike in adult-directed speech, in which the pitch 23 peak may be placed on another part of the utterance (Fernald & Mazzie, 1991). Cutler 24 and Swinney (1987) explicitly showed that children are able to perceive focal accent.

25

1 As an alternative explanation for why children's comprehension of focus may not be 2 adult-like, Cutler and Swinney (1987) proposed that children initially lack full 3 competence concerning the grammar of focus. They attributed children's apparently 4 adult-like production to an innate drive, a 'physiological reflex' to pronounce the parts 5 of the utterance that evoke 'greater excitement' in the speaker with greater prosodic 6 prominence. Specifically, they followed Bolinger's (1983) proposal when they 7 proposed that "the basic mechanism underlying accent is that a greater level of 8 speaker excitation is associated with certain parts of an utterance than with others, and 9 those parts associated with greater excitation will tend to be spoken with prosodic 10 prominence, i.e. accented. It is natural to suppose that the most semantically central 11 parts of an utterance (i.e. the most 'interesting' parts) will be associated with greater 12 excitation; therefore the most semantically central words will be accented" (Cutler & 13 Swinney 1987:163).

14

15 To sum up, in the literature, there are essentially two different explanations to the 16 'paradox of focus acquisition', i.e. that production appears to precede comprehension. 17 What we will call the 'partial competence view' maintains that children's early 18 competence of focus is partial, as reflected by their impaired comprehension abilities. 19 Their production abilities are either also not as fully competent as previously thought 20 (A. Chen, 2010), or only appear to be fully competent by some independent 21 phenomenon masking partial competence (Cutler & Swinney, 1987). In contrast, what 22 we will call the 'full competence view' proposes that children's knowledge of 23 prosodic focus marking is adult-like as reflected by their adult-like production. Early 24 comprehension problems do not reflect a lack of knowledge. Rather, they are due 25 either to a reduced ability to put that knowledge to use (Höhle et al., 2009) or to

independent task effects arising specifically in certain truth-value or felicity judgment
tasks. It is possible that the two are in fact connected. In certain tasks children find it
harder to put their knowledge to use, while other tasks allow them to manifest their
knowledge more easily.

5

6 The current study

7

8 It is thus not yet fully clear whether children below 6 years of age have an adult-like 9 comprehension of prosodically marked focus constructions. Furthermore, most 10 previous experiments only tested English-speaking children. English is a language 11 that makes strong use of prosody to mark different foci. However, as we have already 12 illustrated in (2) for French and German, languages of the world show considerable 13 variation in the extent to which they resort to prosodic means, morphology and syntax 14 being additional focus-marking strategies. In the current study, therefore, we decided 15 to explore the comprehension-production asymmetry in focus processing, using a 16 cross-linguistic perspective. Another reason why a cross-linguistic perspective is 17 warranted is because no cross-linguistic differences are expected under Cutler and 18 Swinney's (1987) partial competence view. If children's production was simply 19 indicating prosodic prominence evoked by 'greater excitement', as they suggest, then 20 this should not be modulated by cross-linguistic differences.

21

Our hypothesis was that children have an adult-like knowledge of prosodic focus marking from an early age. Previous observations to the contrary might result from task-specific constraints that sometimes stop children from putting their knowledge to full use, especially in certain comprehension experiments. Thus, we subscribe to the

1 'full competence view'. Our specific hypotheses were the following: (i) children in all 2 three languages can exploit prosodic salience as a focus marker in comprehension 3 from an early age; (ii) this ability may be modified by the language-specific use of 4 different means to mark focus (with French listeners relying less on prosodic 5 salience); (iii) across languages, object focus utterances correspond to the default 6 accent placement (Liberman & Prince 1977). So, relevant conclusions as to 7 knowledge of prosodic focus marking can only be made based on utterances that do 8 not have the default accent placement but where stress shift is involved, such as 9 subject focus utterances.

10

11 To test these hypotheses, we designed a novel comprehension task, created to 12 alleviate task-specific constraints and semantic-pragmatic ambiguity, to provide the 13 first direct empirical evidence in favor of early adult-like competence in prosodically 14 marked focus comprehension. We tested 3-, 4-, 5-, and 6-year-old children speaking 15 English, German or French to uncover any potential developmental trends and cross-16 linguistic differences. To the best of our knowledge, such a comprehensive, cross-17 linguistic study across the pre-school to school age has not been previously 18 performed.

- 19
- 20
- 21

EXPERIMENT: 3-, 4-, 5- AND 6-YEAR-OLD CHILDREN ARE SENSITIVE TO PROSODIC
FOCUS MANIPULATIONS IN A CORRECTIVE CONTEXT

24

1 To determine whether children show comprehension of focal differences marked by 2 changes in accent placement alone in English, German and French, we designed a 3 comprehension task in which children correct false assertions made by the experimenter with either subject or object focus. Recall that focus marking by 4 5 prosodic accent is an unreliable cue for hearers because prosodic accents can also 6 have other grammatical or emotive functions. This means that in real life, prosodic 7 focus marking is often a superfluous cue: the focus is predictable from the previous 8 discourse. In an experimental situation, we control the discourse and situational 9 context, and make participants have to rely on the prosodic cue alone to identify the 10 focus of the utterance. This is an unnatural and therefore hard task for them. For this 11 reason, we must find a discourse situation where different focus possibilities are 12 expected naturally. Correction is often identified as the strongest pragmatic cue for 13 focus (Féry, 2013). This means that corrective contexts may be sufficiently easy to 14 process for children to potentially show their ability to comprehend focus. For this 15 reason, our experiment involved a scenario where the participant was invited to 16 correct the experimenter's utterance (for similar designs see also S.E. Chen, 1998; 17 Hornby, 1971). In the target condition, children were exposed to a picture while the 18 experimenter made an incorrect assertion with contrastive focal accent on either the 19 subject or the object.

20

21 Method

22 Participants

23 Participants were randomly assigned to one of the two experimental conditions24 (subject or object focus).

25

1

XXX INSERT TABLE 1 HERE XXX

2

3 We tested 52 English native speaker children and 16 English adults, 47 French native 4 speaker children and 11 French adults, and 57 German native speaker children and 11 5 German adults in the SUBJECT condition and 57 English native speaker children and 6 24 English adults, 51 French native speaker children and 10 French adults, and 59 7 German native speaker children and 12 German adults in the OBJECT condition. The 8 exact age ranges are reported in Table 1. The children's parents and teachers reported 9 no cognitive disorders or speech delay. Out of the 372 participants, 203 were females. 10 We tried to keep group sizes as similar as possible, but practical problems resulted in 11 a certain amount of variation. 12 13 Participants with more than one irrelevant or missing response were excluded. We

also excluded participants with less than three correct responses for the fillers. This
resulted in the exclusion of 2 French (age 3: 2), 18 German (age 3: 16; age 6: 1;
adults: 1) and 16 English (age 3: 5; age 4: 9; age 5: 2) participants who were tested in
addition to those included in the analyses described above.

18

19 Material

20

21 The material consisted of test, control and filler items.

22

The test items in both the SUBJECT and the OBJECT condition involved a picture, as
in Figure 1, accompanied by an utterance with subject or object focus, as given in
Table 2.

1

2 XXX INSERT FIGURE 1 HERE XXX

3 XXX INSERT TABLE 2 HERE XXX

4

5 Each visual stimulus depicted two contrast sets (Figure 1): a set of animals (e.g. 6 hedgehog, bird, tiger) and a set of things (e.g. bottle, hammer, shovel). (So each 7 picture contained an animal and an object referred to, a contrasted animal or object as 8 well as a third animal and object distractor.) Based on the idea that marked focal 9 stress on the subject or the object would indicate to the hearer which contrast set is 10 relevant for the speaker, we expected the responses to diverge in the two conditions as 11 follows (see Table 3 for a summary). In the SUBJECT condition, we expected that 12 responses would make reference to the contrast set of animals, e.g. for the test 13 stimulus "The BIRDIE has the bottle, right?" the response is expected to make 14 reference to the hedgehog, which is the animal with the bottle in the picture. In the 15 OBJECT condition, we expected that the responses would make reference to the 16 contrast set of things, in particular, to the hammer, as this is what the bird has in the 17 picture.

18

19 XXX INSERT TABLE 3 HERE XXX

20

The visual stimuli were chosen in such a way that (i) none of the animals or things appeared more salient than the others, (ii) and the names of the animals and things that the experimenter referred to and the participant was expected to refer to are known to 3-year-old children, the youngest age group tested in the study. The words referring to these animals and things in all three languages (i) consisted of (at least)

two syllables, for easy detection of prosodic prominence, and (ii) featured the regular
word stress pattern of the language in question. The position of the contrasting animal
was counterbalanced for side.

4

5 In addition to test items, we also used control items, which were similar in 6 grammatical form to the test items, except that they were true and required no 7 correction by the participant (e.g. *DUCKIE has the scissors, right?* vs. *Duckie has the* 8 *SCISSORS, right?*). These sentences allowed us to test for participants' correct 9 understanding of and attention to the task.

10

Filler items also consisted of an utterance and a corresponding visual stimulus. The visual stimuli were the same as in the test items. The filler utterances were sentences not containing a focus construction. Half of them made a correct, the other half an incorrect statement about the animals or objects in the picture, referring to them as a group (e.g. *All animals are awake.*).

16

The audio stimuli were presented by the experimenter, who was a female native speaker of the experimental language. It was decided that pre-recording utterances would be detrimental to the pragmatic felicity of the experimental situation and would make the task less engaging for the youngest participants. The experimenters were trained to present the stimuli with a clear contrastive focal accent on the subject or object, depending on the condition.

23

24 Procedure

1 Each experimental session started with a warm-up phase to familiarise children with 2 the experimental setup (especially with the task of rejecting and correcting or 3 accepting statements about the pictures) and to make him or her feel comfortable in 4 the testing situation. A puppet was introduced to the children and they were told that 5 the puppet wanted to learn the names of colours. Coloured dots were presented on 6 separate slides on a laptop screen to the puppet and the child. At each slide, the 7 puppet would make a statement about the colour on the screen, which was sometimes 8 correct and sometimes incorrect. Children were encouraged to listen to the puppet's 9 statement and if wrong, correct him, to help him learn the names of the colours. The 10 warm-up phase ended with all the colours appearing on the same screen, and the 11 puppet correctly enumerating their names. After this, the puppet was put on the side, 12 as he was tired after learning all the colours, but remained present for comfort.

13

Before the main test, the experimenter explained that in the next game she will show the participant some pictures, but she herself will not look at them. Rather, she saw them the day before and she will now try to remember them. She then asked the children to correct her if she was wrong, just like they had corrected the puppet earlier.

19

In the main test, participants were presented with 4 test items that were incorrect in a between subjects design (SUBJECT condition and OBJECT condition), 4 control items and 4 fillers. The between subject design was chosen because pilots revealed a strong carry-over effect between the two test conditions. Participants were randomly

assigned to the SUBJECT condition group or the OBJECT condition group.⁴ The 12
 items were presented in two pseudo-random orders, counterbalanced across
 participants.

4

The test session was preceded by a practice session comprising 2 fillers for each 5 6 participant, one of which matched the picture, the other did not match the picture. The 7 practice trials did not use utterances with marked prosody. There was only one way in 8 which the mismatch practice item could be regarded as not matching the picture. If 9 participants failed to provide a correction for the experimenter's mismatched 10 statement, the experimenter encouraged them to do so, including modelling a 11 correction, and explained the task again. In this case, the practice items were repeated 12 to make sure that the participants understood the task clearly. A participant who still 13 failed to perform correctly on the practice items would have been excluded from the 14 study, but that situation did not arise. No feedback was given during the test phase of 15 the experiment.

16

17 Results

18

⁴ In a pilot study we found substantial carry over effects across conditions, which have also been documented in other studies involving prosodic manipulations (Gualmini et al., 2003; Snedeker & Yuan, 2008). For this reason we opted for a between subject design. We agree with Snedeker (2014) that in general children are more sensitive to so-called bottom-up effects in parsing, including lexical and prosodic effects, than adults, and find it harder to inhibit such effects than adults.

1 We coded participants' responses as follows. If in their responses they referred to the 2 relevant member of the contrast set of animals (i.e. the hedgehog in Figure 1), we 3 considered their response as an instance of 'subject correction'. If they referred to the 4 relevant member of the contrast set of things (i.e. the hammer in Figure 1), their 5 response was counted as an instance of 'object correction'. If they referred to both in 6 a single utterance, this response was considered as 'double correction' (e.g. *The birdie* 7 has the HAMMER (and) the HEDGEHOG has the bottle.). If they failed to refer to 8 either of these elements, we treated their responses as 'irrelevant or missing'. We did 9 not analyse the responses prosodically, because many of the responses were single 10 word, fragment responses, where a prosodic analysis makes little sense.

11

12 Before analysing the experimental trials, we checked compliance and general 13 understanding. The proportion of correct (YES) responses in our control items was 14 close to 100% in all groups of the experiment, suggesting that all age and language 15 groups performed the task as expected.

16

17 Participants' responses for the test items are shown in Figure 2 for the three 18 languages, English, French and German respectively. We used the percent subject 19 correction in each of the conditions as the dependent variable in our statistical 20 analyses. Our predictions were that if children have full competence of prosodic 21 focus, then those children who received the SUBJECT condition will give a higher 22 proportion of subject correction responses than those children who received the 23 OBJECT condition. A similar result was expected of adults. The predictions of the 24 partial competence view would be that at least the younger children fail to show a 25 different performance in the two conditions. In terms of cross-linguistic variation, we

expected that French adults may show less sensitivity to our prosodic manipulation,
i.e. less pronounced difference in the proportion of subject responses between the
SUBJECT and OBJECT conditions. Consequently, we were interested to see if this
made it harder for French children to achieve full competence, and that perhaps they
only achieve it later compared to their English and German peers.

6 We performed a three-way ANOVA with between-subject factors Language (English 7 / French / German), Condition (SUBJECT / OBJECT) and Age (3y / 4y / 5y / 6y / 8 adult). We obtained a significant main effect of Condition (F(1,340) = 63.291, p < 9 .0001), because participants in the groups that were exposed to the SUBJECT 10 condition provided more subject corrections than participants in the groups that were 11 exposed to the OBJECT condition. We also found a significant main effect of 12 Language (F(2,340) = 3.5041, p = .0312) due to English participants giving more 13 subject correction responses overall than French participants (Scheffé post hoc test: p 14 = .041).

15

16 Since we used three categories to code responses (subject correction, object correction 17 and double correction), we complemented the above ANOVA with a similar one 18 using the proportion of double corrections as the dependent variable. This ANOVA 19 with between-subject factors Language (English / French / German), Condition 20 (SUBJECT / OBJECT) and Age (3y / 4y / 5y / 6y / adult) revealed a main effect of 21 Language, no effect of Condition or Age and no significant interactions. Scheffé's 22 post hoc tests showed that the main effect of Language was due to the fact that 23 German participants used double correction more often than English participants 24 (although not more often than French participants).

5 DISCUSSION

6

7 In the current study, we tested how 3-, 4-, 5- and 6-year-old English, German and 8 French-speaking children and adults understand prosodically marked subject and 9 object focus in order to investigate whether children already show adult-like 10 comprehension at this age in our correction task. This is relevant as previous studies 11 revealed a potentially paradoxical pattern of results: children were found to produce 12 focus in an adult-like manner much earlier than when they were found to comprehend 13 it. We hypothesized that rather than having a paradoxical competence, children show 14 this behaviour due to task constraints. We therefore designed an experiment to try to 15 circumvent these constraints. We found that, independently of age and language, 16 more subject corrections were provided in the subject condition than in the object 17 condition, suggesting that French, German and English speaking adults and 3-6-year-18 old children are sensitive to the different prosodic marking of subject versus object 19 focus in their comprehension. We also observed, however, that the native language 20 influences this sensitivity, as English participants provided more subject corrections 21 than French participants. We obtained no effect of age, suggesting that 3-year-olds 22 already understand prosodically marked focus. However, it needs to be noted that our 23 individual age groups were relatively small.

24

1 This result supports our hypothesis that prosodic focus marking in the three tested 2 languages is interpreted correctly by children from an early age. This is consistent 3 with the production findings in the literature, which have indicated early mastery of 4 prosodic focus marking. We propose that the inconsistency between our finding and 5 some of the other findings from comprehension experiments can be explained by task 6 effects. The comprehension studies that found that children have difficulties with the 7 interpretation of marked focal stress used explicit judgment tasks. Our experiment 8 used a more naturalistic setting involving a corrective situation, and there was no 9 operator present in our test sentences. The participants had to use the pragmatic 10 information provided in the form of the different accent placements to identify the 11 focus of the utterance and thus identify the relevant contrast set for their correction. 12 But they did not have to make an explicit judgment of pragmatic felicity (cf. A. Chen 13 2010).

14

15 Our study design was quite similar to that of Hornby (1971), but there were two major 16 differences. First, the current test is performed in a pragmatically felicitous situational 17 setting. We are asking the child to check whether the experimenter remembers 18 correctly, thus making correction a highly felicitous response. Second, we have three 19 animal-object pairs in our visual stimuli. We decided to do this, because, a pilot study 20 with only two pairs resulted in a high number of incorrect responses even for adults. 21 Our interpretation of this pilot result was that with only two options in the picture, the 22 relevant contrast can be inferred by exclusion even if the child corrects the non-focal 23 constituent. By way of illustration, if the experimenter says 'The BIRDIE has the 24 bottle', when in fact hedgehog does and birdie has the hammer in the picture, with no 25 third animal-object pair, the focally nonmatching answer 'No, the birdie has the

HAMMER.' is actually an appropriate response. The hearer can draw the simple
inference that if birdie has the hammer, then hedgehog must have the bottle. No such
inference can be drawn with three animal-object pairs in the picture. So, a focally
non-matching utterance is not felicitous in this case.

5

6 The different focal prosodic patterns in our test sentences provided a strong enough 7 cue for participants to determine the relevant contrast set for the correction most of 8 the time. At the same time, focal accent placement on the subject constituent is clearly 9 not an unambiguous cue: prosodic focus does not determine the relevant contrast set 10 for correction in an exclusive manner. Other factors are at play, one of which is the 11 unmarked nature of accent placement on the object in all three tested languages. The 12 object is where main stress falls in neutral (i.e. out of the blue) utterances. Indeed, 13 participants across the board had an object correction bias in their interpretation of the 14 test utterances. This reflects their unwillingness to interpret shifted stress as an 15 indication to determine the relevant contrast set for correction. Similarly, one further 16 factor that might have contributed to our results was the fact that subjects in our test 17 sentences always referred to animate creatures, i.e. different animals, while 18 (grammatical) objects always referred to inanimate things (e.g. bottle). If animate 19 beings are more likely to be interpreted as topics and inanimate things as foci (e.g. 20 Comrie, 1989, Aissen, 1999), then our setup introduced a further object-focus bias 21 into our experiment. This could have contributed to the relatively high proportion of 22 object corrections in the object condition.

23

Another factor that might have contributed to a less than overwhelming proportion ofcorrect performance in both our conditions is the nondeterministic nature of prosodic

1 focus-marking, i.e. that pitch accents do not always mark focus, but can mark other 2 grammatical and emotive content too. Participants understood correctly that prosodic 3 accent can indicate focus, in which case they should use it to determine the intended 4 contrast set, hence the significant difference in the proportion of subject responses 5 between the two conditions, but they did not always interpret the pitch accent as focal, 6 diminishing the proportion of correct responses in the two conditions. Nevertheless 7 our results show that the prosodic information can work against this bias as indicated 8 by the higher number of subject corrections in the SUBJECT-focus condition 9 compared to the OBJECT-focus condition.

10

11 Indications for a cross-linguistic variation in the comprehension of focal accent were 12 revealed by differences between French and English participants, French participants 13 having an overall bias against assigning a subject correction interpretation compared 14 to English participants (Figure 2). This was not unexpected, given that prosodic 15 manipulation of focal stress is less wide-spread in French than in English (Lambrecht, 16 1994; Hamlaoui, 2009a, 2009b) and is subject to more variation (Beyssade et al., 17 2009). So, it is understandable that marked accent on the subject was interpreted by 18 French participants less often as a cue to identify the contrast set of animals as the 19 relevant one for correction. In French, there is a more natural way to express that 20 intended meaning, i.e. the cleft. But, within their overall general reticence to assign a 21 subject focus interpretation to utterances with marked stress, French participants, 22 including children, reacted to the prosodic manipulation in the SUBJECT condition in 23 the expected way.

24

1 One further cross-linguistic difference was revealed by the analysis of the double 2 responses: German participants of all ages provided more double correction responses 3 than English participants independently of the experimental condition. It is possible 4 that despite our best efforts to harmonise experimental practices and training our 5 experimenters in their prosody and in other aspects of the experimental setting, slight 6 differences may have remained, potentially resulting in more double corrections 7 overall in the German group. Given that we tested a subtle pragmatic cue, our 8 experiment is potentially sensitive to minor differences in the testing situation. 9 However, crucially, there was no difference between the proportion of double 10 corrections between the two test conditions, nor between the age groups. Thus this 11 general baseline difference between German and English participants' double 12 corrections notwithstanding, our main findings remain valid. It is of course also 13 possible that the difference in proportion of the double corrections is not caused by 14 an unintended procedural difference but it is in fact genuine. We can only offer a 15 speculation in this direction. Numerically, it seems that the group that showed an 16 eagerness to give double correction responses were the German 6-year-olds. Davies & 17 Katsos (2010) have found that this age-group is particularly prone to over-18 informativeness. By this age, French and English children will have been in formal 19 school education for at least two years. But German children only go to school at age 20 6. So, it is possible that English and French children's natural tendency to give over-21 informative answers at this age would have been dampened by their experience with 22 formal education, where they learnt not to give over-informative answers.

23

Our study only involved three languages, all of which are so-called stress-focuslanguages, which use prosodic means to mark focus. There are some reports of

1 languages that lack prosodic focus marking altogether or have a morphological focus 2 marker, e.g. some Chadic languages (Hartmann & Zimmermann, 2007). At the same 3 time, it appears to be the case universally that languages that have a stress system use 4 stress (or pitch accents more generally) to mark focus (Reinhart, 2006). If further 5 empirical work on different languages turned out to support the validity of this 6 language universal, this would raise the possibility that this stress-focus 7 correspondence is some kind of language primitive. If so, we would in fact expect it 8 to be acquired very early, or potentially already available to children at birth. Our 9 results are consistent with such a state of affairs. In fact, if this is correct, children 10 growing up with languages without stress-focus correspondence would show 11 sensitivity to prosodic focus marking early in development and would lose it as a 12 result of experience with the native language. This is not easily testable empirically 13 though, because the loss of sensitivity might occur too early (S. E. Chen, 1998).

14

Our study did not reveal any developmental change in the acquisition of focus marking, with even 3-year old children showing the same performance patterns as adults on our task. To test whether there is developmental change earlier, future research will need to investigate younger children, perhaps using online measures such as eye tracking to ease the task burden further.

20

On a theoretical level, our results support the 'full competence' view of prosodic focus as opposed to the 'partial competence view', proposed by Cutler and Swinney (1987) and A. Chen (2010). We found that in a pragmatically felicitous task, where children did not have to interpret semantic operators, such as *only*, and where they did not have to make an explicit felicity judgement, they showed adult-like understanding of

1 prosodic focal differences. The reason why Cutler and Swinney's (1987) proposal 2 fails to explain our findings satisfactorily is that according to them accentual 3 information for children is merely an expression of 'greater excitement'. So, for 4 children accentual information is extragrammatical. As a consequence, no cross-5 linguistic differences are expected under Cutler and Swinney's proposal. But we did 6 find such a difference, namely that French participants showed an overall reticence to 7 give subject correction responses compared to English participants, suggesting that 8 prosodic focus marking is rooted in children's knowledge of their native language.

9

10 CONCLUSIONS

11 Our experiment found evidence that children and adults are sensitive to prosodic 12 manipulations of focal accent in English, French and German. Our results therefore 13 support the 'full competence' view of the acquisition of focus, which argues that 14 children's knowledge of prosodic focus marking is in place early. This is in 15 accordance with their adult-like performance in production and also in our 16 comprehension task, which did not rely on a semantically determined truth-value 17 difference between our conditions based on the use of semantic operators, such as 18 only or on explicit pragmatic felicity judgments on the part of the child.

1	LIST OF TABLES AND FIGURES
2	
3	Table 1: English, French, and German participants' break-down of age in the
4	SUBJECT and OBJECT condition
5	Table 2: Example of audio stimulus of test items in English, French and German
6	Table 3: Expected responses to the test items in English, French and German
7	
8	Figure 1: Example of visual stimulus of test item (OBJECT and SUBJECT condition)
9	Figure 2: Proportion of subject corrections, object corrections and double responses
10	by English, French and German 3-, 4-, 5-, 6-year old and adult participants in the test
11	conditions. "S" indicates subject group, "O" indicates object group. Across ages
12	and language groups, proportion of subject correction in subject group is higher
13	than in object group. Overall subject corrections are less frequent for French
14	than English participants.
15	

- Table 1: English, French, and German participants' break-down of age in the
- SUBJECT and OBJECT condition
