ABSTRACT

The chapter provides possible directions for the wider application of the systems approach to information systems development. Potential improvement of software development practices is linked by some leading experts to the application of more systemic ideas. However, the current state of the practice in software engineering and information systems development shows the urgent need for improvement through greater application of systems thinking.

INTRODUCTION

Information Technology (IT) articles often include statements along these lines: “systems development continues to be challenging. Problems regarding the cost, timeliness, and quality of software

products still exist.” (Iivari and Huisman, 2007, p.35). Such a statement justifies the continuous search for improvement of Information Systems Development (ISD). Boehm, one of the founding fathers of Software Engineering, stressed in a recent interview the importance of the systems approach to achieve improvements in software development (see Lane, Petkov and Mora, 2008).

DOI: 10.4018/978-1-61350-456-7.ch7.1

These are some of the origins for the motivation for this paper.

Glass, Ramesh and Vessey (2004) provide an analysis of the topics covered by the three computing disciplines - Information Systems (IS), Software Engineering (SE) and Computer Science (CS) - and show overlaps between them all in the area of systems/software concepts. They also demonstrate that CS has only minor regard of the issues and concerns of systems/software management. Sommerville (2007) states that CS is concerned with the theories and methods that underlie computers and software systems rather than the engineering and management activities associated with producing software. Whilst acknowledging that CS, SE and IS do have a considerable overlap, the practices of both IS and SE have to deal with common matters such as the management of huge development projects, human factors (both software developers and software end users), organizational issues and economic aspects of software systems development and deployment (Van Vilet, 2000).

For the reasons stated above we will concentrate here only on SE and IS and their links to systems thinking. We will consider as a starting point the reality that the whole computing field has evolved historically as several 'stovepipes of knowledge'; CS, SE and IS (Glass et al., 2004). Whether the separation or integration of computing disciplines will prevail is a complex issue. Integration has yet to be achieved as a consequence of the sets of values central to each area. We believe, along with others, that a systems approach may lead to improvement of the development and management of software systems and to a greater integration of computing. One might expect that the use of the word "system" in various contexts today leads to more "systems thinking", but is this true?

A reflective history of the IS field is presented in Hirschheim and Klein (2003, p.244-249). According to them, because of its roots in multiple disciplines, "such as computer science, manage-

ment, and systems theory, it is hardly surprising that the field of IS cast a wide net when defining its boundaries, sweeping in many themes and boundaries" (Hirschheim and Klein, 2003, p.245). In that light, it is somehow striking to note the conclusion about a lack of a systems approach in IS research according to Lee (2004, p.16). Alter (2004, p.757) is even more specific claiming that "the information systems discipline is ostensibly about systems, but many of our fundamental ideas and viewpoints are about tools, not systems".

The systems approach has been acknowledged, in the SE literature, as providing an insight into the factors that influence the success or failure of computer technologies (Mathieu, 2002, p.138). It is symbolic that the 2006 special issue of the IEEE Computer magazine on the 60th anniversary of the IEEE Computer Society was dedicated to the past and future of SE. A brief examination of the papers in that issue shows that four of them are dealing with some systems features and the other three give examples of tool thinking. None of the seven papers issue had a reference to any source from the field of systems thinking and only one paper (Baresi, Di Nitto and Ghezzi, 2006) had references to several classic SE sources dealing with fundamental systems ideas. This does not advance the ideas suggested by Boehm (2006a) and Sommerville (2007) that there is need to integrate SE with Systems Engineering; a branch of systems thinking (see Jackson, 2003).

The contribution of this research is in the identification of areas where a systems approach would lead to improvements in ISD within a point of view that favors implicitly the integration of the IS and SE disciplines. The paper will proceed with an analysis of how links between software development and systems thinking were perceived in the fields of IS and SE. This is done predominantly with the intention of exploring the application of systems ideas to software development separately in the two fields, outlining the success stories and the open problems. At the end we will propose possible directions for future research in software

development within SE and IS associated with the systems approach.

ON INFORMATION SYSTEMS DEVELOPMENT AND SYSTEMS THINKING

A review of the history of various IS development methods is presented in Avison and Fitzgerald (2003). Iivari and Huisman (2007) point out, however, that the research literature on IS development is scarce. This is most evident for the period after 1990. Prior to that point the origins of IS research were associated more strongly with issues on building information systems. However, one sub-area of IS development grew significantly in the UK and elsewhere over the last twenty years; incorporation of Soft Systems Thinking (SST) into IS (see Checkland, 2001).

Soft Systems Thinking and Social Science and their Influence on IS

Stowell and West (1996) argued in the mid 1990's that practices of IS design had not appeared to have progressed since 1979; despite attempts in several proposals to embrace the social aspects of an information system, most seem to be based upon a functionalist view. Stowell and West (1996) explored the shift towards anti-positivism in the mid 1980's which resulted in a number of suggested methodologies that focussed upon the social implications of computer systems design. As examples they point out Soft Systems Methodology (SSM) (see Checkland, 1999), the MULTIVIEW approach (Avison, 2000), participative systems design and others (see also Avison and Fitzgerald, 2003).

SSM evolved originally from experience within interventions in various management problems in public administration and industrial companies. However, subsequently it evolved more towards the field of IS (see Checkland and

Holwell, 1998). Stowell (1995) presents a collection of papers analyzing various aspects of the contribution of SSM to IS. SSM seems to be the most well researched interpretive systems approach used in the field of IS (see Holwell (2000) for a detailed account of the literature on SSM and Checkland and Poulter (2006) for a contemporary presentation of SSM ideas).

The relevance of SSM to the field of IS has been explored in two directions. One way is to apply SSM on its own in some IT related aspect; e.g. extend the standard SSM method to specify the information requirements of the system (see Wilson, 1990). The use of SSM in data modelling is explored by Lewis (1995). A further application of SSM for improvement of software quality is presented in Sweeney and Bustard (1997). A second direction of using SSM in Information Systems is through the linking of SSM to existing design methods. An overview and detailed analysis of using SSM with structured analysis and design is provided by Mingers (1995). Several authors have covered aspects of combining the Unified Modelling Language (UML) with SSM. A recent paper by Sewchuran and Petkov (2007) analyses the related theoretical issues and shows a practical implementation of a combination of UML and SSM within a Critical Systems Thinking (CST) (see Jackson, 2003) framework justified by Multimethodology (see Mingers, 2001).

On Critical Systems Thinking, Multimethodology and IS

Multimethodology is a meta theory for mixing methods from different methodologies and paradigms in the same intervention (Mingers 2001). It seems to be an attractive vehicle for further research in systems thinking and IS research. Further refinement of the ideas on pluralist interventions can be found in a recent paper on Creative Holism (Jackson, 2006). Details on three cases illustrating how Multimethodology and CST were practiced in separate systemic interventions in the

Information and Communications Technologies sector can be found in Petkov, Petkova, Andrew and Nepal (2007).

In his paper on the links between CST and IS research, Jackson (1992) demonstrates the power of an integrated critical approach in the IS field. However, there have been relatively few subsequent publications on the practical application of CST in IS. Some of them are surveyed in Ngwenyama and Lee (1997), a paper demonstrating the significant relevance of CST to IS. Another interesting example, exploring how Triple Loop Learning (Flood and Romm, 1996) can be applied to the complexities during systems development is given in Finnegan, Galliers and Powell's (2002) work. Further papers on systems thinking and IS can be found in proceedings of several meetings on the philosophical assumptions of IS research that took place after 1997; including the UK annual systems conference, the European Conference on Information Systems, the Australasian Conference on IS and Americas Conference on Information Systems (AMCIS).

CST provides both theoretical sophistication and practical directions for future research that are applicable to IS. Jackson (2003) cautions that whatever argument is made in favour of pluralism, it is bound to run up against objections from those who believe in the incommensurability of paradigms. The latter notion is linked to the assumption that if paradigms have distinct and opposing philosophical foundations, applying them together is impossible. This issue has been addressed by several authors in the past (see Jackson, 2003). Zhu (2006), however, questioned recently the relevance of concerns about paradigm incommensurability from a practical point of view; another issue for possible further research. His view on paradigm incommensurability is similar to that of the pragmatic pluralism approach. This is based on the assumption that we are witnessing the end of a particular reading of theory and that there is no single truth and no single rationality (White and Taket, 1996, p.54).

Both pragmatism and functionalism are often criticised in systems thinking (see Jackson, 2003). However, an interesting and relevant new systems approach in IS, the work system method (Alter, 2007), has emerged recently that may be linked to the pragmatic school of thought.

The Work System Method and IS

Alter (2006) stresses that past dominance of single ideas like Total Quality Management and Business Process Reengineering are not sufficient to influence the IS field profoundly. The work system method provides a rigorous but non-technical approach to any manager or business professional to visualize and analyze systems related problems and opportunities (Alter, 2006). This method is more broadly applicable than techniques "designed to specify detailed software requirements and is designed to be more prescriptive and more powerful than domain-independent systems analysis methods such as soft system methodology" (Alter, 2002).

We may note that making comparisons between the work system method and soft systems methodology requires a broader investigation of their philosophical assumptions and scope. A possible starting point for comparing their areas of applicability could be the classification of strategies for doing systems analysis provided by Bustard and Keenan (2005). SSM has been attributed by them to the situation when the focus is on development of a long term vision of the environment in which a computer system is to be used with identification of appropriate organizational changes (see Bustard and Keenan, 2005). Where does Alter's approach stand in the Bustard and Keenan (2005) classification is an open question for research requiring both theoretical work and field experimentation. Petkov and Petkova (2008) consider the systemic nature of the work system method and its applicability to understanding business and IS problems to be its most distinctive and important characteristics. Possible research directions for

incorporating the work system method in systems analysis and design are presented in Petkov, Misra and Petkova (2008). Though the work system method has a relatively short history and a small group of followers for now, the multifaceted scale of Alter's work, bringing together systems ideas with methods for deeper understanding of work systems and ISD, has strong appeal.

On sticking to a single research tradition in IS. Bennetts, Wood-Harper and Mills (2000) provide an in-depth review of combinations of SSM with other IS development methods supporting multiple perspectives along the ideas of Linstone (1984). Thus they brought together two distinct traditions in IS research: the former practiced in UK/Europe/Australia where SSM has found significant acceptance, and the latter being pursued predominantly in the USA. Linstone's ideas are strongly related to the influence of Churchman whose analysis of Inquiring Systems was a starting point for some significant IS research that followed (see as an example Vo, Paradise & Courtney, 2001).

It is interesting to note that Bennetts et al. (2000) have examined sources not only from IS but also from the CS and SE literature. This raises a question that is hard to answer in a simple way. We observe that often authors of SE articles belong to CS or IS departments, rather than engineering schools (Dietrich, Floyd & Klichewski, 2002) (Aurum & Wohlin, 2005). On the other hand, it seems that publications on IS development written by US scholars often use references only from IS or from SE disciplines; depending on the field of the authors (a refreshing exception is a series of articles written over many years by R. Glass and I. Vessey with several collaborators (Glass et al., 2004)). The reason could be the lack of communication between CS, SE and IS (see Glass, 2005). Another possible reason is the growing concern within the separate computing fields for promoting and protecting their own paradigms (Bajaj et al, 2005).

Maybe similar paradigmatic concerns have led Allen Lee to formulate his first idea from an advice

to IS researchers: "practice paradigm, systems thinking and design science" (Lee, 2000). These are seen as a recipe to address the three dilemmas that are as relevant today as they were in 2000: the rigor versus relevance debate in IS research; the "reference discipline" versus "independent discipline" dilemma; the technology versus behaviour as a focus for IS research dilemma.

So far we have considered the second of Lee's ideas and its relevance to IS development over the last 15 years and to a lesser degree some issues related to scientific paradigms in terms of Kuhn (1970). Further details on earlier contributions of Systems Science in the 1970's and 1980's can be found in comprehensive reviews related to the fields of IS research (see Xu, 2000); Decision Support Systems (see Eom, 2000) and Information Resources Management (see McLeod, 1995). Mora, Gelman, Forgionne, Petkov and Cano (2007) presented a critique and integration of the main IS research paradigms and frameworks reported in the IS literature using a systems approach. We briefly comment below on design science, a more recent trend in IS research.

On Design Science as One of the Directions to Resolve the Three Dilemmas in IS

According to Hevner, March, Park and Ram (2004), IS related knowledge is acquired through work in behavioral science and design science paradigms. They point out that "behavioral science addresses research through the development and justification of theories that explain phenomena related to the identified business need, while design science addresses research through the building and evaluation of artifacts designed to meet the particular need". Another relevant detail is the differentiation that Hevner et al. (2004) make between routine design and system building from design science. The former is associated with application of existing knowledge to organizational problems, while the latter is associated with unique (often

wicked or unresolved) problems that are associated with the generation of new knowledge. The latter idea is similar to the main thesis in Hughes and Wood-Harper (1999).

Hevner et al. (2004) laid the foundation for a significant boost in IS research on issues related to IS development, including systems analysis and design science. The journal *Communications of AIS* started a series of articles in 2005 on this topic; the first of which was Bajaj et al. (2005). We may note that in spite of progress in applying action research in IS in theory (see Baskerville and Wood-Harper (1998) and in practice (see the IbisSoft position statement on environment that promotes IS research) the dominant IS research trend has been of a positivist behavioral science type which is another challenge for the proponents of a systems approach.

A substantial attempt to provide suggestions towards resolving the three dilemmas in IS research mentioned by Lee (2000) is discussed in Hirschheim and Klein (2003). They identify a number of disconnects between various aspects of IS research and outline a new body of knowledge in IS development (Iivari, Hirschheim and Klein, 2004). They suggest there are five knowledge areas in ISD: technical knowledge, application domain (i.e. business function) knowledge, organizational knowledge, application knowledge and ISD process knowledge. Further, according to Hirschheim and Klein (2003) “ISD process knowledge is broken down into four distinctive competencies that IS experts are suggested to possess: (1) aligning IT artefacts (IS applications and other software products) with the organizational and social context in which the artefacts are to be used, and with the needs of the people who are to use the system as identified through the process of (2) user requirements construction... (3) organizational implementation from which (4) the evaluation/assessment of these artefacts and related changes is factored out ... These competencies are ... at best weakly taken into account in the ten knowledge areas of SWEBOK” (see for

comparison SWEBOK, 2004). Hirschheim and Klein (2003) present comprehensive proposals for strengthening the IS field. Their work was partly motivated by a widely discussed paper by Benbasat and Zmud (2003) on the identity crisis in the IS discipline. Both papers provide important background details about the IS research environment in which one may pursue the main ideas of this paper.

ON SOFTWARE ENGINEERING AND SYSTEMS THINKING

Software Engineering has a primary focus on the production of a high quality technological product, rather than on achieving an organisational effect, however increasing emphasis in SE is being given to managerial and organisational issues associated with software development projects. Cornford and Smithson (1996) observe that SE “can never encompass the whole range of issues that need to be addressed when information systems are studied in the full richness of their operational and organisational setting”.

Weinberg (1992) writes about systems thinking applied to SE. It is an excellent introduction to systems thinking and quality software management dealing with feedback control. It has a close kinship with the concepts of systems thinking and system dynamics in Madachy (2008), even though it is almost exclusively qualitative and heuristic. Weinberg’s main ideas focus around management thinking about developing complex software systems; having the right “system model” about the project and its personnel.

Systems thinking in the context of SE as described in Madachy (2008) is a conceptual framework with a body of knowledge and tools to identify wide-perspective interactions, feedback and recurring structures. Instead of focusing on open-loop event-level explanations and assuming cause and effect are closely related in space and time, it recognizes the world really consists

of multiple closed-loop feedbacks, delays, and non-linear effects.

Lee and Miller (2004) advocate a systems thinking approach in their work on multi-project software engineering pointing that “in general, we are able to make better, more robust, and wiser decisions with systems thinking, since we are considering the problem by understanding the full consequences of each feasible solution”.

Other details on systems thinking with links to other books and articles can be found through practitioner’s web sites such Weinberg (2007), Developer (2007) or Yourdon (2007). The interest of software practitioners in systems ideas is a significant fact; in light of the previously mentioned debate about relevance in the IS literature. However, systems thinking is not mentioned by Reifer (2003) in his taxonomies of the SE theory state-of-the-art and SE state of practice. In relation to that, we will discuss below whether systems ideas are promoted in SE education.

Software Engineering Education and Systems Thinking

The coverage of systems concepts in leading SE textbooks is possibly another indicator about the way the systems approach is perceived within the SE community. We considered books by several well established authors: Sommerville (2007), Pressman (2009) and Pfleeger (2008) amongst many. Table 1 shows a summary of findings related to the treatment of several typical systems notions in those books.

Table 1 shows that the systems concepts covered in the three widely used textbooks are mostly related to introductory notions from systems thinking. There is nothing about open and closed systems, about the law of requisite variety or any other aspect of cybernetics, very little about socio-technical systems and nothing about soft systems methodology or CST. In our opinion these are unexploited notions that have some potential to introduce fresh ideas in SE after further research.

Table 1. Systems features covered in popular software engineering textbooks

Notions covered	Author		
	Sommerville	Pressman	Pfleeger
System definition	Yes	Yes	Yes
Boundary	Implied	Yes	Yes
Open vs Closed systems	No	No	No
Relationships	Implied	Implied	Yes
Interrelated systems	Implied	Implied	Yes
Emergent property	Yes	No	No
Decomposition	Yes	Yes	Yes
Coupling	No	Yes	Yes
Cohesion	No	No	Yes
Hierarchy	Yes	Yes	Yes
System behaviour	Yes	Yes	Yes
Law of requisite variety	No	No	No
Socio-technical systems	Yes	No	No
Systems engineering	Yes	To some extent	To some extent

Crnkovic, Land and Sjogren (2003) question whether the current SE training is enough for software engineers. They call for making system thinking more explicit in SE courses. They claim that “the focus on modifiability (and on other non-functional properties) requires more of a holistic and system perspective” (Crnkovic et al., 2003). Similar thoughts are shared more recently by others in engineering like Laware, Davis and Perusich (2006).

The narrow interpretation of computing disciplines is seen as a contributory factor to the drop in student enrolments in the last five years. Denning (2005) hopes that students will be attracted by a new educational approach promoted by the ACM Education Board that relies on four

core practices: programming, systems thinking, modelling and innovating. It has now been four years since those ideas were stressed by ACM but there is little evidence that systems thinking has become a core practice emphasized in teaching in any of the three computing disciplines.

In the UK the Quality Assurance Agency (which monitors and quality assures all UK university programmes) recently published the updated version of the Computing benchmark statement (encompassing IS, SE and CS) on the content and form of undergraduate courses (QAA, 2007). Although not intended to be an exhaustive list but "... provided as a set of knowledge areas indicative of the technical areas within computing" it fails to make explicit reference to systems thinking or systems approaches and makes only one reference to "systems theory" under a more general heading of "systems analysis and design". Perhaps the answer is to explore how to introduce these concepts earlier in pre-university education or to continue to try to convince the broader academic community of the importance of systems thinking.

One promising systems approach used for education of software engineers is the Model-Based System Architecting and Software Engineering (MBASE) framework being used at USC, and also adapted by some of their industrial affiliates. According to Boehm (2006c), MBASE integrates the systems engineering and SE disciplines, and considers stakeholder value in the system development. The MBASE framework embodies elements of agile processes, and teaches students to "learn how to learn" as software development will continue to change. Valerdi and Madachy (2008) further describe the impact of MBASE in education.

On Software Engineering and Systems Engineering

Systems Engineering is concerned with all aspects of the development and evolution of complex sys-

tems where software plays a major role. Systems engineering is therefore concerned with hardware development, policy and process design and system deployment, as well as software engineering. System engineers are involved in specifying a system, defining its overall architecture and then integrating the different parts to create the finished system. Systems engineering as a discipline is older than SE; people have been involved in specifying and assembling complex industrial systems such as aircraft and chemical plants for more than a hundred years (Sommerville, 2007).

A thought provoking comparison of SE culture versus systems engineering culture is presented by Gonzales (2005). This work points out to where we should strive to change the perceptions of the SE student entering the IT profession. We agree with Gonzales (2005, p.1) that we "must continue the dialogue and ensure that we are aware of strides to formalize standard systems engineering approaches and generalize software engineering approaches to capturing, specifying and managing requirements". We would also suggest that this dialogue should be supported by more work on the application of a systems approach to SE; stimulated by journals such as the International Journal on Information Technologies and the Systems Approach (IJITSA).

Boehm (2006b) concludes that "The push to integrate application-domain models and software-domain models in Model Driven Development reflects the trend in the 2000's toward integration of software and systems engineering". Another reason he identifies is that other surveys have shown that the majority of software project failures stem from systems engineering shortfalls. A similar thought is expressed by Boehm and Turner (2005), who state that there is a need to move towards a common set of life-cycle definitions and processes that incorporate both disciplines' needs and capitalize on their strengths.

Boehm (2006a) points out that "recent process guidelines and standards such as the Capability Maturity Model Integration (CMMI), ISO/IEC

12207 for software engineering, and ISO/IEC 15288 for systems engineering emphasize the need to integrate systems and software engineering processes". He further proposes a new process framework for integrating software and systems engineering for 21st century systems, and improving the contractual acquisition processes.

A very recent development illustrates the increasingly recognized importance of applying systems thinking to large and complex acquisition processes for software-intensive systems. The United States Department of Defense (DoD) just created a long-term Systems Engineering Research Center (SERC) as a consortium of universities. The SERC leverages developments in systems architecting, complex systems theory, systems thinking, systems science, knowledge management, and software engineering to advance the design and development of complex systems across all DoD domains (Stevens Institute of Technology, 2008).

As the first research centre focused on systems engineering, it is specifically concerned with integrating systems and SE. Some research areas include software-unique extensions and modern software development techniques and how they relate to systems engineering; flexible systems engineering environments to support complex software systems and commercial-off-the-shelf hardware and software integration; and other aspects involving SE and IS (Stevens Institute of Technology, 2008).

Part of the SERC acquisition research is to further develop the Incremental Commitment Model (ICM) (Boehm & Lane, 2007) for better integrating system acquisition, systems engineering, and SE. The ICM is a risk-driven process generator for incremental development of complex systems that uses the principles of MBASE with both plan-driven and agile process components.

An issue is how to capitalize on these new and upcoming developments in SE as will be discussed in the next section.

The Evolution of Plan-Driven and Agile Methods in SE and System Thinking

The traditional software development world, characterised by SE, advocates use plan-driven methods which rely heavily on explicit documented knowledge. Plan-driven methods use project planning documentation to provide broad-spectrum communications and rely on documented process plans and product plans to coordinate everyone (Boehm & Turner, 2004). The late 1990s saw something of a backlash against what was seen as the over-rigidity contained within plan-driven models and culminated in the arrival of agile methodologies, which rely heavily on communication through tacit, interpersonal knowledge for their success.

Boehm and Turner (2004, p.23) quote Philippe Kruchten (formerly with IBM Canada and now a professor at UBC in Vancouver) who has likened the Capability Maturity Model (CMM) – a plan-drive approach - to a dictionary; "that is, one uses the words one needs to make the desired point-there is no need to use all the words available". They conclude that processes should have the right weight for the specific project, team and environment. Boehm and Turner (2004) have produced the first multifaceted comparison of agile and plan-driven methods for software development. Their conclusions show that neither provides a 'silver bullet' (Brooks, 1987). Some balanced methods are emerging. We need both agility and discipline in software development (Boehm & Turner, 2004, p.148).

Boehm (2006b) presents a deep analysis of the history of SE and of the trends that have emerged recently. These include the agile development methods; commercial off-the-shelf software and model driven development. The same author points out that the challenges are in capturing the evolving IT infrastructure and the domain restructuring that is going on in industry. In our opinion it is necessary to investigate further if systems

thinking may play a role in integrating agile and plan-driven methods (see Madachy, Boehm & Lane (2007) as an application of systems thinking to this problem). It has also been speculated that systems thinking could be relevant to Extreme Programming (XP) as it supports building relevant mental models (see Wendorff, 2002).

Kroes, Franssen, van de Poel and Ottens (2006) deal with important issues in systems engineering; such as how to separate a system from its environment or context. They conclude that the idea that a socio-technical system can be designed, made and controlled from some central view of the function of the system, has to be given up as many actors within the socio-technical system are continuously changing (redesigning) the system. This is an important issue deserving further investigation in light of software systems and the methods implied by agile development frameworks.

Systems Dynamics and SE

A widely publicized idea is modelling software development processes through systems dynamics (see Abdel-Hamid & Madnick (1991), Madachy (2008) and others). The differences and relationships between systems dynamics and systems thinking are detailed in Richmond (1994) and others. Systems dynamics is a tool that can assist managers to deal with systemic and dynamic properties of the project environment, and can be used to investigate virtually any aspect of the software process at a macro or micro level. It is useful for modeling socio-technical factors and their feedback on software projects. The systems dynamics paradigm is based on continuous systems modeling, which has a strong cybernetic thread. Cybernetic principles are relevant to many types of systems including software development systems, as detailed in Madachy (2008).

The primary purposes of using systems dynamics or other process modeling methods in SE as summarized from Madachy (2008) are strategic

management, planning, control and operational management, process improvement and technology adoption and training and learning. Example recent work by Madachy (2006) focuses on the use of systems dynamics to model the interaction between business value and the parameters of a software process for the purpose of its optimization. Another application of systems dynamics to assess a hybrid plan-driven and agile process that aims to cope with the requirements of a rapidly changing software environment while assuring high dependability in Software-Intensive-Systems-of-Systems (SISOS) is presented in Madachy, Boehm and Lane (2007).

On Other Methods of Systems Thinking Applicable to SE

The development of understanding of a particular software project for making better judgments about the cost factors involved in cost and effort estimation is supported also by the work of Petkova and Roode (1999). They implemented a pluralist systemic framework for the evaluation of the factors affecting software development productivity within a particular organizational environment. It combines techniques from several paradigms; stakeholder identification and analysis (from SAST, see Mason and Mitroff, 1981), from SSM (Checkland, 1999), Critical Systems Heuristics (Ulrich, 1998) and the Analytic Hierarchy Process (Saaty, 1990).

While we could not find any specific earlier accounts of the use of SSM in the mainstream SE literature, it is significant that Boehm has recognised its potential as he quotes its originator in a recent paper: "... software people were recognizing that their sequential, reductionist processes were not conducive to producing user-satisfactory software, and were developing alternative SE processes (evolutionary, spiral, agile) involving more and more systems engineering activities. Concurrently, systems engineering people were coming to similar conclusions about their sequential, reductionist

processes, and developing alternative ‘soft systems engineering’ processes (e.g., Checkland, 1999), emphasizing the continuous learning aspects of developing successful user-intensive systems” (Boehm, 2006a).

One does not need always to have a systems philosophy in mind to generate an idea that has a systemic nature or attempts to change the current thinking in SE. Thus, Kruchten (2005) presents, under the banner of postmodernist software design, an intriguing framework for software design borrowed from architecture. One may investigate how such an approach is different from a systemic methodology and what are their common features. Starting from a language-action philosophy point of view, Denning and Dunham (2006) develop a framework of innovation based on seven practices that are interrelated in their innovation model – every element is in a relationship with all others, thus fulfilling the criterion for “systemicity” by Mitroff and Linstone (1993). We need more analogical examples of systemic reasoning or even just of alternative thinking related to every aspect of the work of a software engineer and IS developer demonstrating the power of innovative interconnected thinking. The analysis so far allows us now to formulate some recommendations in the following section.

CONCLUDING RECOMMENDATIONS ON THE NEED FOR MORE RESEARCH LINKING SOFTWARE ENGINEERING, INFORMATION SYSTEMS DEVELOPMENT AND SYSTEMS THINKING

We may derive a number of possible directions for future work from the analysis of research and practice in ISD and systems thinking within the fields of IS and SE. Alter (2004) has produced a set of recommendations for greater use of systems thinking in the IS discipline which incorporate various aspects of the work system method. We

believe that Alter’s proposals are viable and deserve the attention of IS and SE researchers.

Boehm and Turner’s (2005) suggestions to address management challenges in integrating agile and plan-driven methods in software development will be used by us as an organizing framework for formulating directions for research on integrating IS, SE and the systems approach. The five main points below are as defined originally by Boehm and Turner (2005) for their purpose, while we have provided for each of them suggestions promoting such integration along the aims of this paper:

1. **Understand how communication occurs within development teams:** There is a need to continue the work on *integrating systemic methods promoting organizational learning* (see Argyris and Schon, 1978) like systems dynamics, stakeholder analysis, soft systems methodology, critical systems thinking and others to identify the advantages of using specific methods and their limitations when dealing with uncovering the micro climate within a software development team. Most of the previously mentioned applications of systems methods for this purpose have had limited use and little experimental evaluation. *More case studies need to be conducted in different software development organizations to validate the claims for the applicability of such methods and to distil from the accumulated knowledge best practices and critical success factors relevant to flexible, high quality software development teams.* We may *expand further the boundary of investigations with respect to what is happening at the level of systems-of-systems* (see Sage, 2005). An example of related relevant ideas on cost estimation for large and complex software projects can be found in Lane and Boehm (2007). Another direction is to *explore information systems development as a research act*, as suggested by Hughes and Wood-Harper (1999) and

Hevner et al. (2004, as well as the philosophy of integrating practice with research in the field of software and management, promoted by IbisSoft.

2. **Educate stakeholders:** This is probably the most difficult task of all. It needs to be addressed at several levels:

- **Implement changes in educational curricula:** it is essential to introduce the systems idea in relatively simple forms at undergraduate level and in more sophisticated detail at masters' level. There is *a need to create the intellectual infrastructure for more doctoral dissertation projects in IS or SE involving systems thinking*. Teaching could be supported by *creating an accessible repository for successful utilization of systems ideas in IT education*. Among the many examples we may mention here the use of SSM in project-based education at a Japanese university (Chujo & Kijima, 2006), on integrating systems thinking into IS education (see Vo, Chae & Olson, 2006), or the use of MBASE in student projects (see Boehm (2006c) and Valerdi & Madachy, 2007).
- **Broaden the systems knowledge of IS and software engineering educators:** the current situation in some of the computing disciplines can be compared to a similar one in Operations Research (OR) in the 1960s, which had evoked a sharp critique by Ackoff (1999) in his famous paper "The future of operational research is past", published originally in 1979. Ackoff (1999, p.316) points that survival, stability and respectability took precedence over development and innovativeness in OR in the mid 1960's and its decline began. *The challenge however is not just to*

bring systems thinking to IS and SE education beyond several elementary concepts of general systems theory but to keep up to date with the latest body of knowledge in the systems field. For a comprehensive overview see Jackson (2003) and for recent developments in systems science, see Barton, Emery, Flood, Selsky and Wolstenholm (2004)

- **Empower IT developers to practice systemic thinking:** a significant role here needs to be played by research on the most *suitable forms for continuing professional education on IT and the systems approach, supported by professional meetings and journals for mixed audiences* like this one, that are oriented to academia and industry practice. Ackoff (2006, p.707) underlines that one of the reasons why systems ideas are adopted by few organizations is that "very little of the systems literature and lectures are addressed to potential users". Further he stresses the need to analyse management failures systemically, pointing out that there are two types of failures: errors of commission and errors of omission. In spite of publications analysing software failures like Glass (2001), *there is still room for systemic analysis of IT failures and there are very few accounts of errors of omission* in software projects.
- **Change the attitudes of clients in managerial and operational user roles:** viable research and practical activities in this direction could *use the work system method* (Alter, 2006) and other relevant methods to develop better understanding of organizational problems and to improve

their communication with software developers.

3. **Translate agile and software issues into management and customer language:** We may suggest several possible directions here:
 - **Investigate in a systemic way the existing agile and plan-driven models** for software development and continue with the work started in Boehm (2006a) on creating new process models integrating not just SE and systems engineering ideas but other applicable systems concepts as well.
 - **Explore the applicability of “Sysperanto”** (see Alter, 2007) to foster a common language for all stakeholders in software development.
 - **Build methods and tools to facilitate the communication process between software developers, and customers and supporting multiple perspective** representations of problem situations as proposed by Linstone (1984).
4. **Emphasize value for every stakeholder:** Design science research and agile methods place high emphasis on this idea. There is a *need for more research on systemic identification of stakeholder values*. Further there is a need for research on methods to model and help the effective analysis and *better systemic understanding of all aspects of software development*, related to the technical product attributes, the project organizational attributes, the developers attributes and the client features in a particular project or system-of-projects.
5. **Pick good people, reward the results and reorient the reward system to recognize both individual and team contribution:** These suggestions can be categorized as human resource management issues and hence are also suitable for *investi-*

gation through suitable systemic approaches and problem structuring methods, including multi-criteria decision analysis, promoting evaluation and decision making.

One of the limitations of the scope of our proposals is that we have provided suggestions reflecting only on the above five ideas by Boehm and Turner (2005). A systemic investigation of all aspects of ISD could lead to a much broader set of considerations integrating SE, IS and systems thinking. We believe, however that the examples we have provided here can lead to easier adaptation and development of other relevant ideas serving a similar purpose. Another possible limitation is that we have produced our suggestions for future research on integrating SE, IS and the systems approach by assuming that the current state of the art and practice in SE and IS are known and we have focused rather only on identifying examples of the use of a systems approach in IS or SE. As we have pointed earlier, we have relied on the comprehensive analysis of the state-of-the-art of the IS discipline provided by Hirschheim and Klein (2003). We have also reflected on trends in SE (see Reifer (2003), Boehm (2006a, b) and Boehm and Turner (2004)) and on the comparative analysis of research in the three computing disciplines by Glass et al. (2004). It would be interesting to conduct a further investigation of IS implementation as a whole that goes beyond the existing disciplinary boundaries and takes a systems approach as an organizing viewpoint.

Most of our recommendations on integrating IS, SE and systems thinking relate to issues of organizational learning where contemporary systems methods have a significant history of achieving improvement. The relevance of this paper is supported by Boehm’s recent interview, mentioned earlier (see Lane et al., 2008). The challenge for IS and SE practitioners, researchers and educators is not just to investigate the issues we discussed in this paper but also to practice the systems approach for improved ISD.

ACKNOWLEDGMENT

The authors are very grateful to D. Bustard, I. Bider, M. Mora and D. Paradise for their insightful comments that helped improve an earlier version of the paper that was published in IJITSA in 2008.
