Received 27 July 2012; accepted 10 September 2012

Key indicators: single-crystal X-ray study; T = 123 K; mean  $\sigma(C-C) = 0.003 \text{ Å}$ ; disorder in main residue; R factor = 0.036; wR factor = 0.100; data-to-parameter ratio = 12.1.

The title compound, C<sub>2</sub>H<sub>2</sub>·C<sub>12</sub>H<sub>24</sub>O<sub>6</sub>·2NH<sub>3</sub>, was formed by cocrystallization of 18-crown-6 and acetylene in liquid ammonia. The 18-crown-6 molecule has threefold rotoinversion symmetry. The actevlene molecule lies on the threefold axis and the whole molecule is generated by an inversion center. The two ammonia molecules are also located on the threefold axis and are related by inversion symmetry. In the crystal, the ammonia molecules are located below and above the crown ether plane and are connected by intermolecular N-H···O hydrogen bonds. The acetylene molecules are additionally linked by weak C-H···N interactions into chains that propagate in the direction of the crystallographic c axis. The 18-crown-6 molecule [occupancy ratio 0.830 (4):0.170 (4)] is disordered and was refined using a split model.

# Acetylene-ammonia-18-crown-6 (1/2/1)

## Tobias Grassl, Markus Hamberger and Nikolaus Korber

#### Comment

The crystal structure of the title compound was determined in the course of investigations regarding the reactivity of acetylene in liquid ammonia.

In the crystal structure the acetylene molecule shows moderate hydrogen bonding in axial direction to an ammonia molecule on each side with a H···N distance of 2.3422 (15) Å and a C—H···N angle of 180°. Two ammonia molecules are located below and above the crown ether plane, bound by hydrogen bonds to the oxygen atoms in the ring (Fig. 1 and Fig. 2). Both ammonia molecules are connected to 18-crown-6 *via* three hydrogen bonds each with a H···O distance of 2.40 Å and a N—H···O angle of 171.0° for the crown ether part with a site occupation factor of 0.83 and with a H···O distance of 2.43 Å and a N—H···O angle of 159.4° for the crown ether part with a site occupation factor of 0.17 (Fig. 2 and Table 1). This arrangement leads to one-dimensional strands along the crystallographic *c*-axis, that are packed in a kind of hexagonal closest arrangement (Fig. 3). The formation of hydrogen bonds between acetylene and ammonia molecules as well as the interaction of ammonia molecules with the crown ether is essential to stabilize the fugitive acetylene molecule in the solid state as was shown previously by Boese *et al.* (Boese *et al.*, 2009) in C<sub>2</sub>H<sub>2</sub>\*NH<sub>3</sub>. Due to the absence of stronger intermolecular interactions the optimization of hydrogen bonds is the driving force for the axial stacking of the molecules along the crystallographic *c*-axis. This can also be observed in acetylene containing material such as co-crystallized C<sub>2</sub>H<sub>2</sub>\*NH<sub>3</sub> (Boese *et al.*, 2009) and co-crystals of acetylene and acetone/DMSO (Boese *et al.*, 2003) or azacycles (Kirchner *et al.*, 2004).

#### **Experimental**

0.039 g(1.0 mmol) potassium and 0.264 g(1.00 mmol)18-crown-6 were placed under argon atmosphere in a baked-out reaction vessel and 30 ml of dry liquid ammonia were condensed. The mixture was stored at 236 K for one week to ensure that all substances were completely dissolved. Afterwards an excess of acetylene gas was fed into the solution until the colour changed from deep blue to colourless. Colourless crystals of the title compound were obtained after further storage at 236 K for nine month. Well soluble potassium hydrogen acetylide KC<sub>2</sub>H remained in solution.

#### Refinement

The O atom and one C atom of the crown ether are disordered and were refined using a split model with sof of 0.830 (4) and 0.170 (4). The C—H H atoms were positioned with idealized geometry and refined isotropic with  $U_{iso}(H) = 1.2$   $U_{eq}(C)$  using a riding model. The N-H H atom was located in difference map and refined in the riding mode approximation.

Refinement	

#### Refinement

Refinement on  $F^2$ Secondary atom site location: difference Fourier Least-squares matrix: full  $R[F^2 > 2\sigma(F^2)] = 0.036$ Hydrogen site location: inferred from  $wR(F^2) = 0.100$ neighbouring sites S = 1.11H-atom parameters constrained 640 reflections  $w = 1/[\sigma^2(F_0^2) + (0.0481P)^2 + 0.8298P]$ where  $P = (F_0^2 + 2F_c^2)/3$ 53 parameters 0 restraints  $(\Delta/\sigma)_{\rm max} < 0.001$  $\Delta \rho_{\rm max} = 0.18 \text{ e Å}^{-3}$ Primary atom site location: iterative  $\Delta \rho_{\min} = -0.19 \text{ e Å}^{-3}$ 

#### Special details

Experimental. Absorption correction: Crysalis Pro, Agilent Technologies, Version 1.171.35.21, Analytical numeric absorption correction using a multifaceted crystal model based on expressions derived by R. C. Clark & J. S. Reid (1995).

Crystal mounting in perfluorether

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted R-factor wR and goodness of fit S are based on  $F^2$ , conventional R-factors R are based on F, with F set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on  $F^2$ are statistically about twice as large as those based on F, and R- factors based on ALL data will be even larger.
