1. ZUSAMMENFASSUNG

Um menschliche Krankheiten besser verstehen zu können, ist eine genaue Analyse der Genexpression in gesunden und kranken Zellen notwendig. Obwohl der Transkription von Genen traditionell eine wichtige Rolle beigemessen wird, zeigen aktuelle Studien, dass auch Reifung, Transport, Stabilität und Translation der transkribierten mRNA wichtige Faktoren darstellen, welche in der Zelle streng kontrolliert werden. Die Stabilität vieler mRNAs wird von Sequenzen bestimmt, die sich im nicht translatierten 3' Bereich befinden und die Bindung bestimmter Proteine und/oder miRNAs ermöglichen. Eines dieser Proteine ist Tristetraprolin, kurz TTP. TTP erkennt und bindet RNA-Sequenzen, die reich an A- und U-Nukleotiden sind und führt mithilfe anderer Faktoren, die TTP als Plattform nutzen, zum raschen Abbau der mRNA.

Viele Gene, wie beispielsweise TNF α und Interleukin-1 β , deren mRNA-Stabilität auf diese Weise von TTP kontrolliert wird, spielen eine wichtige Rolle in der Immunabwehr. In Mäusen führt daher der systemische Verlust des TTP-Gens bzw. das daraus resultierende Ungleichgewicht im Immunsystem zur Entwicklung diverser Pathologien wie Dermatitis und Rheumatoider Arthritis. Diese lassen sich auf eine erhöhte TNF α mRNA-Stabilität zurückführen. Um die Funktion von TTP in diversen Krankheiten genauer erforschen zu können, wurde im Zuge dieser Arbeit eine Maus generiert, deren TTP-Gen nun zelltypspezifisch deletiert werden kann. Unterbindet man die TTP-Expression dieser Mäuse in myeloiden Zellen, so entwickeln sich diese Tiere vorerst normal. Versetzt man ihnen allerdings einen endotoxischen Schock, so sterben sie schneller, was darauf hinweist, dass myeloides TTP eine wichtige Rolle bei der Kontrolle der Immunantwort während einer akuten Entzündung spielt. Wir konnten weiters zeigen, dass TTP die Stabilität vieler mRNAs steuert, die während einer Entzündung produziert werden. Viele TTP-Funktionen wiederum werden durch die p38 MAP-Kinase kontrolliert. Diese Kinase erhöht einerseits die TTP-Expression

und stabilisiert das TTP-Protein, blockiert andererseits aber auch den mRNA-Abbau durch TTP. Damit wird sichergestellt, dass am Beginn einer Entzündung, wenn also die p38 MAP-Kinase aktiv ist, nur wenige mRNAs in TTP-abhängiger Weise abgebaut werden. Im späteren Verlauf reduziert sich die p38 MAP-Kinase-Aktivität allerdings zusehends, wodurch sich der TTP-abhängige Abbau vieler mRNAs verstärkt. In dieser Phase wird die Stabilität von mehr als einem Drittel aller instabilen mRNAs, deren Expression durch die Entzündung aktiviert wurde, durch TTP reguliert. Drei dieser Gene (Interleukin-6, Interleukin-1 α und Cxcl2) wurden für detailliertere Untersuchungen ausgewählt und erwiesen sich als echte TTP-Targets.

Zusätzlich identifizierten wir Interleukin-10 als einen weiteren Faktor, der den TTP-abhängigen mRNA Abbau kontrolliert. Interleukin-10 wird erst im späteren Verlauf einer Entzündungsreaktion produziert und erhöht dann die TTP-Expression. Zusätzlich blockiert Interleukin-10 mit der Zeit immer mehr die p38 MAP-Kinase und steigert so die Aktivität von TTP. Befindet sich die Entzündung in der Auflösung, so führt letztlich der völlige Einbruch der p38 MAP-Kinase-Aktivität zu einem raschen Abbau von TTP, womit der Ausgangszustand wiederhergestellt ist.

Diese Doktorarbeit beschreibt einen regulatorischen Kreislauf, der den Abbau von bis zu einem Drittel aller instabilen mRNAs kontrolliert, die während einer Entzündung induziert werden. Ein wichtiges Element in diesem Kreislauf ist TTP, da es die Akkumulation für die Entzündung wichtiger mRNAs zu Beginn zulässt, im späteren Verlauf diese aber rasch aus dem System entfernt. Daher spielt TTP eine wichtige Rolle für den Erhalt des immunologischen Gleichgewichts.

2. SUMMARY

Uncovering control of gene expression in healthy and abnormal cells is of uppermost importance for the understanding of human pathologies. While a lot of attention has been paid to the gene expression control at the transcriptional level, in recent years even more studies focused on mRNA maturation, transport, stability and translation. mRNA stability and translation are critically regulated by cis-acting sequences located in the 3' untranslated region (3' UTR) that act by recruiting various RNA-binding proteins (RBPs) and/or miRNAs. Tristetraprolin (TTP), a well known RBP, binds to AU-rich elements (AREs) within the 3' UTR thereby causing a rapid degradation of the targeted mRNA by facilitating the assembly of enzymes for decapping, deadenylation as well as 5'-to-3' and 3'-to-5' exonucleases.

Animal models as well as *in vitro* studies revealed a profound role of TTP in controlling immune homeostasis by regulating mRNA stability of inflammatory mediators such as TNF α and interleukin-1 β (IL-1 β). Conventional TTP knockout mice develop severe inflammatory pathologies like rheumatoid arthritis and dermatitis that were linked to increased *Tnf* mRNA stability. Because of the very poor health and infertility of these animals, the precise function of TTP in animal models for inflammatory diseases could not be addressed. Thus, one project of this PhD thesis was to generate and characterize mice with a conditional TTP ablation. Animals deleted for TTP in myeloid cells appear healthy but are more susceptible to LPS-driven endotoxic shock, pointing out the so far unrecognized importance of myeloid-specific TTP in limiting the acute inflammatory response. Detailed analysis revealed that TTP is a critical player in a relay of negative feedback mechanisms that regulates the removal of a large proportion of unstable mRNAs produced upon inflammation. This feedback employs as a second factor the p38 MAPK, that influences TTP function in multiple ways: i) it induces TTP transcription and stabilizes TTP protein against degradation; ii) it inhibits the mRNA-destabilizing function of TTP by phosphorylation. When p38 MAPK activity is high immediately after LPS stimulation, only few mRNAs can be targeted by TTP for degradation.

However, as p38 MAPK activity gradually decreases at later stages of the inflammatory response, the TTP-mediated mRNA decay becomes more apparent. Microarray analysis revealed that at low p38 MAPK activity, more than one third of inflammation-induced unstable mRNAs are degraded in a TTP-dependent fashion. For the three candidate targets *IL-6*, *IL-1 α* and *Cxcl2*, a set of additional experiments provided the evidence that they were true TTP targets. We furthermore show that the TTP-dependent mRNA decay was increased in part by IL-10. IL-10, that is produced later during inflammation, boosts TTP function both by enhancing TTP transcription and by increasing TTP mRNA-destabilizing activity through the inhibition of p38 MAPK. The complete drop of p38 MAPK activity during the resolution phase of inflammation ultimately leads to the degradation of TTP, resulting in reversion into the original state.

This study describes a regulatory circuit that controls the timely removal of one third of unstable inflammation induced mRNAs. A critical component of this circuit is the mRNA-destabilizing protein TTP whose function is regulated such that it allows a high accumulation of the early phase inflammatory mRNAs and their efficient removal during the later phase of the inflammatory response when these mRNAs are no longer needed. Thus, by controlling mRNA stability TTP fundamentally contributes to immune homeostasis.

3. Introduction

3.1 Transcriptional and Posttranscriptional Regulatory Networks

In eukaryotes, posttranscriptional mechanisms controlling various aspects in the life of an mRNA are known to be important regulators of gene expression. In this respect, RNA binding proteins (RBPs) have proven to be of critical importance. RBPs regulate RNA maturation, transport, stability and translational efficiency contributing to cellular homeostasis and gene expression dynamics [1]. Several new studies indicate that global changes in RNA stability are of particular importance during inflammatory responses [2].

Inflammation induced by pathogens as well as by sterile stimuli (e.g. TNF α , IL-1) trigger a massive reprogramming of gene expression [3]. Interestingly, the immediately activated genes generate mRNAs that display high and quick induction followed by a rapid decline. The mRNAs in this set of genes are very unstable and are enriched in AU-rich elements (AREs) in the 3' untranslated region (3' UTR) [2]. AREs have been known for a long time to control mRNA stability, therefore providing a link between the expression pattern seen and mRNA stability [4]. Regulatory circuits controlling globally gene expression at the level of transcription have been recently described [5]. However, networks regulating global mRNA stability both in time and quality during the cellular response to external stimuli are still elusive. They are likely to be dependent on RNA stabilizing and destabilizing proteins as well as miRNAs.

3.2 Posttranscriptional Gene Regulation by Tristetraprolin (TTP)

Tristetraprolin (TTP) is a Cys-Cys-Cys-His (CCCH) type tandem zinc-finger protein encoded by the gene *zfp36*. TTP was cloned independently by several groups as an immediate early

gene induced by insulin, phorbol ester and serum [6-8]. Almost 10 years ago the Blackshear laboratory described TTP as protein that binds to *Tnf* and *GM-CSf* mRNA and causes rapid deadenylation and mRNA decay [9, 10]. The tandem zinc-fingers responsible for RNA-binding in the center of the protein are flanked by three proline-rich regions reflected by the name TTP [11]. The N- or C-terminal domains of TTP provide a platform for several effector-proteins like enzymes involved in decapping and deadenylation as well as exonucleases [12, 13]. Up to now, TTP was shown to regulate mRNA stability of various transcripts in several cell-types (reviewed in [14]).

3.2.1 AU-rich elements (AREs)

TTP has been first described to directly bind to AU-rich elements (AREs) of mRNAs leading to rapid mRNA decay [9]. AREs are sequence elements rich in adenosine and uridine bases located in the 3' UTR of mRNAs. Based on the number and distribution of the core ARE pentamer AUUUA, generally three classes have been defined. Class I AREs contain several dispersed copies of AUUUA often found in a uridine-rich environment. Class II AREs have at least two overlapping UUAUUUAWW nonamers whereas Class III AREs are less well defined as uridine-rich regions containing no AUUUA pentamer [15]. Structural properties keeping AREs in a single- or double-stranded conformation have been described to be of importance for some ARE-binding proteins as HuR. In this study, oligonucleotides were designed that can turn a double-stranded ARE sequence into a single-stranded conformation. Subsequent HuR binding assays revealed that HuR preferentially associates with the single-stranded RNA form [16].

AREs have been found in as much as 4000 human mRNAs, representing 5-8% of human genes when searching for a 13 bp pattern of WWWU(AUUUA)UUUW with one mismatch allowed in the pentamer flanking region [17]. Between mouse and human approximately 25 % of the ARE clusters (as defined previously in [18]) of orthologous genes show significant

differences [19]. This means that there is a profound variation of the ARE pattern between species.

First evidence for a functional role of AREs in mRNA degradation was provided by cloning of the ARE sequence of the *GM-CSf* into an otherwise stable *globin* mRNA, causing rapid mRNA degradation [4]. To date, AREs have been implicated in posttranscriptional gene regulation by regulating mRNA decay through various mechanisms and/or by affecting translational efficiency. They are therefore predominantly found in genes that need to be in precise control of expression like many cytokines and growth factors [20].

3.2.2 TTP binding sites

TTP was initially shown to directly interact by its zinc finger domains with a stretch of several AUUUA sequences within the ARE located in the 3' UTR of *Tnf* [9]. Further studies using RNA SELEX revealed a preference for the extended UUAUUUAUU sequence rather than the simple AUUUA form [21]. However the TTP zinc finger domain has been shown to have an optimal affinity for a binding site consisting of two adenosine residues located 3-6 bases apart within a uridine-rich region [22]. Although AREs have been shown in numerous studies to be the main site for TTP binding, recent work suggests that also messages devoid of any ARE can be targeted by TTP [23, 24].

3.2.3 TTP targets

Upon binding, TTP was described to mediate deadenylation of *Tnf* and *GM-CSf* mRNA leading to rapid degradation [9, 10]. Since then, other targets have been found in various cell systems to be directly or indirectly targeted for degradation by TTP. For instance, in T lymphocytes TTP is induced upon TCR and CD28 co-receptor stimulation leading to increased *IL-2* and *IFN γ* mRNA decay [25, 26]. Various other cytokine mRNAs as *Cxcl1*, *IL-1 β* , *IL-10* and *IL-3* have been shown to be targeted for degradation by TTP [27-31]. In

addition also *zfp36* mRNA, encoding TTP protein, has been suggested to be targeted by TTP forming an autoregulatory loop [32].

The human *inducible NO synthase (iNOS)* mRNA becomes destabilized in DLD-1 cells upon inhibition of p38 MAPK signaling which is consistent with a TTP-mediated decay. For this reason, *iNOS* was tested for direct interaction with TTP. However, coimmunoprecipitation studies revealed that TTP does not directly bind *iNOS* mRNA. Instead TTP interacts with yet another RNA binding protein KSRP that can bind to *iNOS* mRNA. KSRP mediates mRNA decay by attracting the exosome. TTP was therefore proposed to stabilize *iNOS* mRNA by capturing the KSRP-exosome complex [33].

A study comparing the mRNA decay-rate of Wt and TTP-deficient fibroblast by microarray analysis could define a set of 250 mRNAs stabilized in the TTP-deficient background. Although 8 of them were further tested by Northern blotting, only *ler3* mRNA was characterized in detail to be a true TTP-target [24]. Two more global screens in dendritic cells and macrophages using RNA immunoprecipitation suggested a number of so far unknown TTP-targets [23, 27]. However, mRNAs identified by global screens as putative TTP-targets (e.g. *IL-6*, *IL-12* and *Cxcl2* [34, 35]) cannot be considered as true TTP-targets unless further tested, in order to reveal whether a message is directly bound by TTP and regulated at the level of mRNA decay.

3.2.4 TTP-mediated control of mRNA stability

TTP is transiently expressed in response to many stimuli e.g. LPS, TNF α , IL-4, TGF β , glucocorticoids and interferons and then rapidly shuttles to the cytoplasm [36-41]. TTP was initially described to lead to rapid deadenylation and mRNA decay by recruiting poly(A) RNase [42]. However, recent studies indicate, that TTP is in a complex with 3'-5' exonucleases (e.g. CCR4), 5'-3' exonucleases (e.g. Xrn1), decapping enzyme as Dcp1 as well as with exosomal components. These data suggest a function for TTP as molecular link

between ARE-containing mRNAs and different mRNA decay machineries leading to 3' to 5' as well as 5' to 3' degradation (figure 1) [12, 43, 44].

Figure 1: TTP by its N- and C-terminal domain (NTD, CTD) recruits different decay enzymes to targeted mRNAs providing a binding-platform for rapid degradation (figure from reference [12]).

In addition to the classical decay-pathways, also proteasome dependent mechanisms seem to be involved in TTP function. Therefore proteasome inhibition results in an impaired TTP function as shown recently [45].

In response to certain stressors, TTP can associate with cytoplasmic foci called stress granules (SGs) [46]. SGs are distinct sites within the cytoplasm of mammalian cells, forming upon eukaryotic initiation factor 2 α phosphorylation during cellular stress [47]. These foci store untranslated mRNAs for reuse or transport to yet other cytoplasmic structure called GW bodies/processing bodies (PBs), where mRNAs are decapped and degraded [48]. TTP has been shown to promote the association between SGs and PBs therefore contributing to PB-dependent mRNA degradation. The current model assumes that during certain stress

conditions, mRNAs get released from polysomes and are delivered to SG where they are remodelled or sorted for degradation by PB in a TTP-dependent way [49].

3.2.5 Involvement of TTP in microRNA-dependent mRNA degradation

Beside the regulation of mRNA decay via cis-acting sequences in the 3'UTR, noncoding RNAs and microRNAs (miRNAs) have been extensively studied to influence RNA degradation and translation [50, 51]. Recent studies indicated that a specific miRNA, miR16, containing a UAAAUAUU sequence, is required for ARE-mediated mRNA turnover. This mRNA degradation is ARE and TTP-dependent. TTP interacts through association with Ago/eiF2C family members with the aforementioned miRNA facilitating ARE-mediated mRNA decay [52].

3.2.6 Functions of TTP not linked to mRNA decay

Aside its function in regulating mRNA stability, TTP has recently been shown to play a role in NF- κ B signaling. TTP expression as well as NF- κ B signaling are activated upon TNF α stimulation. However, TTP impairs the nuclear import of the NF- κ B transcription factor unit p65 thereby blocking specific ARE-less NF- κ B target genes independently of its function in mRNA degradation. This finding adds yet another level of possible regulation of gene expression by TTP during cellular stress [53, 54].

3.3 Posttranscriptional Regulation of TTP

3.3.1 p38 MAPK

Since the p38 Mitogen-activated protein kinase (MAPK) plays a fundamental role in the regulation of TTP, the general features of MAPK signaling are described in this paragraph. MAPKs are conserved serine/threonine protein kinases of cytoplasmic and nuclear targets

activated through phosphorylation by upstream MAPK kinases (MAP2K). The three known MAPK pathways, the Jun N-terminal kinase (JNK), the p38 MAPK and the extracellular signal-regulated kinase (ERK) pathway convert extracellular stimuli into a wide range of different responses. JNK and p38 MAPK pathway are also called stress kinase pathways as they are predominantly activated by environmental stress and pro-inflammatory cytokines thereby playing a key role during inflammation (figure 2) [55, 56].

Among the four p38 MAPK family members (p38 α , p38 β , p38 γ and p38 δ), p38 α has been most extensively studied and appears to be the most widely expressed isoform [57]. Depending on the cell type, p38 MAPK is activated by a broad range of stress stimuli like LPS, hypoxia, toxins, UV radiation and pro-inflammatory cytokines such as IL-1 [58]. p38 MAPK then either activates MAPK-activated protein kinases (MKs) or directly phosphorylates sequence-specific transcription factors, transcriptional co-regulators and factors controlling mRNA stability and translation explaining the wide range of p38 MAPK-regulated biological processes (e.g. proliferation, survival, differentiation, inflammation and cancer) [55, 59]. Among the MKs activated by p38 MAPK are MK2, MK3, mitogen- and stress-activated kinase 1 and 2 (MSK1, MSK2), MAPK-interacting kinase 1 and 2 (MNK1, MNK2) and p38 regulated/activated kinase (PRAK) [59-61].

In macrophages, p38 MAPK is activated by TLRs and regulates the expression of a broad set of pro-inflammatory mediators (e.g. TNF α , IL-1 and IL-6) by both transcriptional and posttranscriptional mechanisms [57]. p38 MAPK has been proposed to affect specifically the stability of ARE-containing mRNAs such as *IL-3*, *IL-6* and *IL-8* by regulating TTP [62, 63]. However, besides a profound contribution for the onset of inflammation, p38 MAPK is also known to induce anti-inflammatory gene expression [61]. Activation of p38 MAPK and its downstream kinases MSK1 and MSK2 by LPS leads to increased IL-10 and dual-specific phosphatase-1 (DUSP1) expression. IL-10 and IL-10-induced DUSP1 have been demonstrated to inhibit p38 MAPK signaling therefore creating a negative feedback loop that limits the inflammatory response [64-66].

Figure 2: Stress-activated JNK and p38 MAPK pathways are activated by a wide range of environmental stresses. Upstream activators (e.g. MAP3Ks and MAP2Ks family members) and downstream targets (e.g. transcription factors and other effectors) of p38 MAPKs and JNKs are depicted (figure from reference [55]).

3.3.2 Transcriptional and posttranscriptional control of TTP

TTP was discovered as an immediate early gene because its mRNA is rapidly induced after serum stimulation in fibroblast. In macrophages, TTP mRNA is induced after LPS stimulation in a p38 MAPK dependent way and disappears to baseline within a few hours [39, 67]. In contrast to the labile mRNA, TTP protein appears stable after LPS treatment and gets slowly phosphorylated at different sites as shown by several studies [68-70]. p38 MAPK and its downstream kinase MAPKAP kinase-2 (MK2) can directly phosphorylate TTP [71-73]. Phosphorylation by MK2 of serines 52 and 178 leads to the exclusion of TTP from SGs by the assembly of 14-3-3:TTP complexes [46]. In association with 14-3-3, TTP is resistant to protein phosphatase 2a (PP2A)-dependent dephosphorylation and appears to be impaired in

promoting mRNA decay [46, 73] (figure 3). However, phosphorylated TTP is more stable as indicated by experiments using the specific p38 α and p38 β MAPK inhibitor SB203580. Thus, inhibition of p38 MAPK results in rapid dephosphorylation of TTP, relocalization from the cytoplasm to the nucleus and proteasomal degradation [70]. TTP is suggested to be stored and stalled by phosphorylation in a less active state till mRNA degradation of distinct messages is needed [70, 74]. p38 MAPK mediated regulation of TTP therefore happens at many levels, controlling TTP transcription as well as subcellular localization, protein stability and TTP activity [23, 33, 41, 48].

Figure 3: Inhibition of TTP-mediated mRNA decay by p38 MAPK phosphorylation and subsequent 14-3-3:TTP complex formation during stress (figure from reference [75]).

3.4 Role of TTP in Inflammation and Disease

TTP-deficient mice appear normal at birth but soon develop a complex phenotype. One to eight weeks after birth their weight gain rate starts to decrease followed by cachexia. In addition the animals develop multiple signs of inflammation as dermatitis, arthritis and conjunctivitis. Also several abnormalities of the hematopoietic system were detected like thymic hypoplasia and splenomegaly with a marked increase in myeloid cells especially in the bone marrow. However, treatment with TNF α antibody did prevent almost all aspects of the TTP-deficiency phenotype tested pointing out an important role of TTP in regulating *Tnf* mRNA stability [76]. Consecutive bone marrow transplantation experiments using bone marrow from TTP-deficient animals could mimic the phenotype seen in TTP-deficient mice. However, as the phenotype developed after a long latent period, the authors suggested that not lymphocyte progenitors but rather slowly reconstituting cells as cells of the monocyte/macrophage lineage are responsible for the phenotype seen in these animals [77]. In human, TTP gene polymorphism analysis revealed up to 35 SNPs with a potential role in rheumatoid arthritis patients as well as other diseases [78, 79]. As pathologically stable transcripts are known to play a role in cancer development, reduced TTP levels have been associated with increased tumor incidents and progression. In this context, TTP has been shown to control mRNA stability of *Cox-2*, *IL-8*, *IL-3* and *VEGF* mRNA in different cancer models [80-83].

3.5 Interleukin-10 Signaling

mRNA stability is a major determinant for the expression of inflammatory molecules [2]. In this context, ARE-mediated mRNA decay by ARE-binding proteins like TTP and AUF1 is known to be important for limiting the inflammatory response providing a new strong anti-inflammatory mechanism [76, 84]. One of the most potent anti-inflammatory pathways is the interleukin-10 (IL-10) signaling cascade. Interestingly, the effectors of this pathway are largely unknown. IL-10 has been known for a long time to play a pivotal role as a potent anti-inflammatory cytokine, although its expression is induced by signaling pathways predominately driving inflammation as p38 MAPK pathway [65, 85]. IL-10 affects inflammation at the transcriptional as well as at the posttranscriptional level.

The pleiotropic IL-10 family of cytokines includes IL-19, IL-20, IL22, IL-24, IL-26, IL-28 and IL29, all sharing genetic similarities and affecting a broad range of biological functions [86]. IL-10 is produced by many cell types as various T-cell types, B-cells, monocytes and macrophages as well as granulocytes [87-91]. Binding of IL-10 to a complex of two IL-10 receptor 1 (IL-10R1) and two IL-10 receptor 2 (IL-10R2) molecules on most cells activates downstream Janus tyrosine kinases JAK1 and Tyk2. These kinases phosphorylate the cytoplasmic tails of the receptors recruiting STAT3 molecules. Activated STAT3 homodimers translocate subsequently to the nucleus and bind to STAT-binding sites on various promoters (figure 4) [85, 92]. We and others could demonstrate that IL-10 signaling plays a major role by controlling p38 MAPK induced inflammation. IL-10 drives expression of DUSP1 at later stages during the inflammatory response leading to gradually inactivation of p38 MAPK [64]. As a consequence, TTP gets rapidly dephosphorylated thereby increasing TTP activity [30]. IL-6 also signals via STAT3, though IL-6 signaling does not reproduce the anti-inflammatory properties of IL-10. This difference has been attributed to STAT3 driven SOCS3 expression. SOCS3 can bind and therefore inactivate the gp130 subunit of the IL-6 receptor, but not the IL-10 receptor. This means that IL-10 signaling allows a prolonged STAT3 activation

necessary for DUSP1 activation and down-regulation of p38 MAPK signaling [64, 93-95]. As a part of this PhD thesis it could be shown that the IL-10-dependent inhibition of p38 MAPK causes dephosphorylation of TTP thereby increasing the TTP-mediated mRNA degradation of the pro-inflammatory cytokines TNF α and IL-1 α . These results established TTP as one of the effector molecules of IL-10 signaling (see Schaljo B. and Kratochvill F. et al. figure 3A and 5C in [30]).

Figure 4: IL-10 signals via Jak1/Tyk2-STAT3 pathway (figure from reference [85]).

3.6 Other ARE Binding Factors

TTP remains the best described ARE-binding protein. However, several other proteins can bind to AREs in the 3' UTR of mRNAs controlling many features in the lifecycle of a nascent RNA. These proteins have been implicated in modulating not only mRNA stability, but also translational efficiency, transport and localization. As most of these proteins can target many RNAs in the cell, ARE-binding proteins are assumed to be main contributors in the global regulation of gene expression [96].

3.6.1 *TIS11 family*

The mammalian TIS11 family consist of the 4 members TTP (synonyms: TIS11, ZFP36, Nup475, GOS24), TIS11b (synonyms: Berg36, ERF-1, ZFP36L1, BRF-1), TIS11d (synonyms: ZFP36L2, ERF-2, BRF-2) and Zfp36l3 which is solely expressed in mouse placenta and the only TIS11 member not containing a functional nuclear export signal [14, 97, 98]. In other organisms TIS11 homologues have been identified as well. DTIS11 in *Drosophila* for instance, shares 90% sequence identity with murine TIS11b and TIS11d [99]. In *Saccharomyces cerevisiae* two members of the CCCH zing finger protein family, Cth1 and Cth2, have been cloned [100]. These two proteins degrade a battery of message involved in Fe-dependent metabolism [101, 102].

All TIS11 proteins and homologues have been described to be involved in mRNA degradation and bind to targeted transcripts by a conserved CCCH-type tandem zinc finger domain (figure 5) [14]. These domains are highly conserved within the murine TIS11 family so that most authors have made the assumption that the RNA binding affinity of the 3 murine TIS11 proteins is very similar [98].

Figure 5: Ribbon diagram showing the first zinc-binding domain of TTP determined by multidimensional nuclear magnetic resonance spectroscopy. The metal binding site is depicted in dark grey and the leucine-rich core in black (figure from reference [103]).

Although these proteins are related and share common targets, they have distinct physiological roles. In contrast to the phenotype seen in the TTP knockout mouse described above, mice ablated for TIS11d die within 2 weeks of birth by developing intestinal and other hemorrhage. Further analysis revealed defective hematopoiesis and a role for TIS11d in hematopoietic stem and progenitor cell development [104]. Deletion of the third family member, TIS11b, results in abnormal placentation and early fetal death suggesting a developmental defect [105].

A possible explanation for the non-redundant role of the 3 TIS11 family members *in vivo* is provided by the finding that these proteins show major differences in the steady state protein levels in different cells and tissues as well as different expression-patterns in response to

stimulation or during developmental processes. *TTP* mRNA for example appears to be expressed at a similar level in human monocytes as *TIS11b* and *TIS11d*. However *TTP* is much higher induced in response to external stimuli like LPS. Therefore *TTP* is supposed to contribute to a larger extent to the regulation of mRNA stability during inflammation in these cells, accounting for almost 70 % of all *TIS11* transcripts after LPS treatment [98].

3.6.2 *AUF1*

AUF1 (AU-binding factor 1), also known as hnRNP D (heterogeneous nuclear ribonucleoprotein D), comprises four protein isoforms (p37, p40, p42 and p45) generated by alternative splicing [106]. Every isoform contains two RNA recognition motifs through which they bind to AREs within selected mRNA targets. *AUF1* was originally found to promote mRNA decay [107, 108], though it was also shown to stabilize transcripts as well as to promote translation [109, 110]. The broad spectrum of *AUF1* targets, ranging from immune factors as *Tnf*, *IL-6* and *IL-1 β* to genes affecting differentiation and carcinogenesis like *Cox-2* and *cyclin D1*, suggests a role of general importance of *AUF1* in the cell [109, 111-114]. *AUF1* knockout mice show a normal development, but appear to be more susceptible to LPS driven endotoxic shock due to an overproduction of *IL-1 β* and *TNF α* [84]. Notably, while *TTP* knockout mice spontaneously develop various signs of inflammation due to an elevated *TNF α* level [76], loss *AUF1* cannot recapitulate any of these syndromes [84]. This suggests that *AUF1* and *TTP* have different properties in ARE-mediated mRNA decay. *AUF1* executes *Tnf* mRNA degradation only upon activation of pro-inflammatory cytokines such as during LPS-challenge [84]. *TTP* in contrast was thought to control *Tnf* mRNA degradation independently of an inflammatory stimulus in the mouse, providing an explanation for the various syndromes of spontaneous inflammation developed in the conventional *TTP* knockout mouse [76]. However, as *TTP* expression is rapidly and transiently induced in macrophages in response to LPS, it is likely that *TTP* plays a role during acute forms of stress as well [39]. Accordingly, LPS stimulated *TTP*^{-/-} macrophages produce higher levels

of proinflammatory cytokines as TNF α [77]. The role of TTP in acute inflammation has been confirmed in this PhD thesis by examining LPS-induced endotoxic shock in myeloid-specific TTP deletion.

3.6.3 *Hu proteins*

The Elav or Hu protein family, named after the *Drosophila* ortholog ELAV (embryonic lethal-abnormal vision) and their appearance as tumor-specific antigens in paraneoplastic neurological disorders in man, comprises the ubiquitous expressed HuR and the neuronal members of the family HuB, HuC and HuD. While HuB, HuC and HuD play important roles in neuronal differentiation and plasticity, the function of HuR is more related to cellular stress responses [115-119]. HuR binds to labile mRNAs bearing AU- or U-rich motifs in the 3' UTR increasing their stability or modifying translational efficiency [16, 120, 121]. Among the messages targeted by HuR are genes important in cell cycle control and proliferation as *cyclin A* and *c-fos* [122, 123] as well as mediators of carcinogenesis and inflammation like *VEGF*, *Cox-2* and *Tnf* [124]. Since HuR shares many mRNA targets with TTP, it has been proposed to counteract TTP-mediated mRNA degradation. Indeed, in various types of tumors HuR levels are elevated whereas those of TTP are reduced [82, 125, 126]. In normal colon tissue for instance, low HuR and higher TTP levels can be observed. However, in most adenomas and adenocarcinomas HuR expression is elevated and TTP expression is lost [82].

Recent HuR knockout studies in mice revealed, that global deletion leads to embryonic death around midgestation as a consequence of an impaired development of the extraembryonic placenta. Postnatal deletion of HuR leads to atrophy of hematopoietic organs, loss of intestinal villi and obstructive enterocolitis as a consequence of increase apoptosis of progenitor cell in the bone marrow, thymus and intestine depicting a role of HuR during development [127, 128].

3.6.4 KH-type splicing regulatory protein

The ARE-binding protein KSRP (KH-type splicing regulatory protein, also known as KHSRP) is known to regulate mRNA stability of several targets as *c-fos*, *iNOS*, *parathyroid hormone (Pth)*, *Tnf*, *IL-2* and *IL-8* in a phosphorylation-dependent manner by recruiting mRNAs to the exosome and poly(A) ribonuclease (PARN) [129-134]. It has been demonstrated that KSRP undergoes p38 MAPK dependent phosphorylation during muscle differentiation which leads to impaired target-mRNA binding similar to TTP [134]. TTP is able to bind to KSRP thereby impairing KSRP mediated mRNA degradation of *iNOS* as described [33]. Recent studies implicated a role for KSRP in the biogenesis of a subset of miRNAs. In doing so, KSRP binds as a component of the Dicer complex to the terminal loop of miRNA precursors promoting their maturation [135, 136].

3.6.5 TIA-1 and TIAR

TIA-1 and its homologue TIAR are closely related ARE-binding proteins. Both bind with 3 conserved RNA recognition motifs (RRM) domains with high affinity to uridine-rich domains [137]. TIA1 knockout macrophages produce elevated levels of TNF α protein, although *Tnf* mRNA levels and transcript stability is not affected. Accordingly, TIA-1 deficiency leads to increased association with polysomes establishing TIA-1 as a silencer of translation [138]. Along its role in translation, TIA-1 and TIAR have been described to regulate splicing as well as the transport of untranslated mRNAs to SGs adding yet another function for RBPs [47, 139, 140].

3.6.6 NF90

The RNA-binding protein nuclear factor 90 (NF90), also known as NFAR (nuclear factor associated dsRNA), binds to and regulates the stability, transport and translation of several targeted mRNAs. As binding site, a 25 to 30 nucleotide long RNA signature motif rich in

adenines and uridines has been elucidated [141, 142]. The gene that encodes NF90 can, by alternative splicing, give rise to yet another protein called NF110. However, so far NF110 has not been studied in detail [143]. In addition to mRNA regulation, NF90 has been shown to bind to the *IL-2* promoter in T-cells controlling *IL-2* transcription. Hence, T-cell specific NF90 ablation in mice leads to impaired *IL-2* transcription and mRNA stabilization [144]. As NF90 has been also implicated in binding double-stranded RNA, it is supposed to be involved in the response to viral infections [144-147].

4. Aims

The precise regulation of gene expression is critical for the response to external stimuli as seen during inflammation. Besides control at the transcriptional level, posttranscriptional mechanisms have been shown to be of key importance. Herein mRNA stability enables the cell to induce a robust expression of selected transcripts upon transcriptional induction by impairing mRNA degradation. On the other hand, when transcription ceases a mechanism must be in place that rapidly removes transcripts from the system when they are no longer needed. Since TTP represents an mRNA-destabilizing factor that plays an important role in the removal of several inflammatory mRNAs it was decided to investigate its contribution to the global regulation of mRNA decay and to immune homeostasis. The aims of the PhD thesis were:

1) Contribution of TTP to global mRNA decay and elucidation of the regulatory circuits involved therein

One aim of this thesis was to globally identify mRNAs targeted by TTP for degradation during inflammation. In addition, it should be examined how the quality and quantity of the TTP-dependent mRNA decay is regulated in time during inflammatory response. Herein, the function of p38 MAPK and IL-10, the key pro- and anti-inflammatory molecules, respectively, should be investigated.

2) Studies of the role of TTP in inflammatory models using conditional deletion of TTP in mice

As the biological role of TTP-dependent mRNA degradation in diseases is only poorly understood, we aimed to establish a mouse line conditionally deleted for *zfp36*, the gene coding for TTP. This knockout mouse should then be used to elucidate the role of TTP in different animal models for inflammation-related human diseases.

5. MATERIALS AND METHODS

5.1 Cytokines, Reagents and Antibodies

p38 MAPK antibody was purchased from Santa Cruz (Santa Cruz, CA, USA). Rabbit antibody to TTP was obtained by immunizing rabbits with 44 C-terminal amino acids of murine TTP fused to GST. LPS from *Escherichia Coli* 055:B5 (Sigma-Aldrich, USA) was used at a concentration of 10 ng/ml for cell culture or 62.5 mg/kg for *in vivo* LPS challenge. Actinomycin D (act D) and SB203580 (all Sigma) were used at a concentration of 5 µg/ml and 4 µM, respectively.

5.2 Mammalian Cell Culture

5.2.1 Cell lines

Murine embryonic fibroblasts were grown in DMEM supplemented with 10 % FCS. Abelson-transformed B-cell clones were grown in complete RPMI medium (RPMI (PAA, Germany), 10 % FCS and 5 µM β-mercaptoethanol).

5.2.2 Primary cells

Primary macrophages, isolated from bone marrow of tibia and femur, were cultured in L cell-derived CSF-1 as previously shown [148]. Mice were housed in specific pathogen-free conditions and were 6-10 weeks of age at the time of bone marrow preparation. Conventional TTP-deficient mice (TTP^{-/-}) were on C57Bl/6 background. Conditional TTP knockout mice (TTP^{fl}) and conditional knockin mice overexpressing TTP (Col1^{tm1(TTP)}); hereafter referred to as TTP^{high}) were on 129/OlaHsd C57Bl/6 mixed or C57Bl/6 background as specified in each experiment. TTP^{fl} LysMCre mice and TTP^{high} LysMCre mice were

obtained by crossing TTP^{fl} and TTP^{high} mice with the knockin LysMCre mouse line B6.129P2-Lyzs^{tml(cre)lfo} (Jackson Laboratories Bar Harbor, Main, USA) on C57Bl/6 background. Mouse experiments were performed according to the national law.

5.2.3 Abelson-transformation and colony formation assay

For the preparation of Abelson-transformed B-cell progenitors, bone marrow from Wt or TTP^{-/-} mice (C57Bl/6) was infected for 1 hour with viral supernatant derived from A010 cells supplemented with IL-7 (10 ng/ml) and polybrene (10 µg/ml) or left uninfected (mock). A010 cells produce an ectopic replication-deficient form of the Abelson virus described previously [149]. Cells were then maintained in complete RPMI medium supplemented with IL-7 for 15-20 hours. Thereafter cells were maintained in complete RPMI medium to generate growth factor independent cell lines or were plated in cytokine-free methylcellulose at a density of 2.5×10^5 cells/ml in 35-mm dishes for 6-12 days in order to calculate cloning efficiency by counting colonies.

5.3 Construction of Targeting Vector and Generation of Conditional TTP Knockout Mice

For conditional ablation of *zfp36* (encoding TTP), we created a deletion construct containing exon 2 of *zfp36* (the larger of the two *zfp36* exons) flanked by *LoxP* sites in front of an also *LoxP* site flanked neomycin (Neo) cassette. Therefore exon 2 was PCR amplified as well as a 1 kb region 3' downstream and a 5 kb region 5' upstream of exon 2 allowing homologous integration on the TTP locus. As template for the PCR reactions we purchased a Bac clone from Geneservice (BioCat GmbH, www.geneservice.co.uk), containing the genomic TTP

locus. The PCR products for exon 2, the 3' down- and the 5' upstream sequence of exon 2 were created using the following primers (respective restriction sites are underlined):

For exon 2 with the inclusion of Sall and Xbal restriction sites:

Exon 2 fw (Sall): 5'- ATC CTT GTC GAC TCC TCT CAG AGC CTC CAG T -3'

Exon 2 rv (Xbal): 5'- TGG ACC TCT AGA TCA CTC AGA GAC AGA GAT AC -3'

For the 3' downstream region with the inclusion of NotI and ClaI restriction sites:

3' region fw (NotI): 5'- GGA CGA GCG GCC GCC AAG TGC CTA CCT ACC CAG -3'

3' region rv (ClaI): 5'- GAG TTC ATC GAT GAA ACA TCC CGT TCC TGC C -3'

The primer set for the 5' upstream region was designed to create XhoI and HindIII sites at the end of the PCR fragment:

5' region fw (XhoI): 5'- **ACG TCT** CCT CGA GGC CAG CCA AAG TGG CTT AT -3'

5' region rv (HindIII): 5'- **ACG TCT** CAA GCT TAC AGG GTT CGG TTA GGC CA -3'

As there are also XhoI and HindIII sites located inside the 5' upstream region, the flanking XhoI and HindIII sites were created using the restriction enzyme Esp3I. This enzyme cuts one nucleotide on the leading and five nucleotides on the lagging strand downstream of a distinct recognition site (highlighted in bold).

The resulting products were inserted into the Sall/Xbal, NotI/ClaI and XhoI/HindIII restriction sites of the vector pEasy Flox (Addgene, Cambridge, USA; figure 6) respectively, creating the targeting vector depicted in figure 9A.

Figure 6: pEasy Flox; TK, thymidine kinase; Neo, neomycin.

The final vector was sequenced by Eurofins MWG Operon (Germany). Then the vector was linearized by ClaI digestion and electroporated into 129/OlaHsd embryonic stem cells (ES cells) using an Amaxa Nucleofector Kit according to the manufacturers protocol. Single cell clones were selected for Neo resistance and then isolated for further cultivation on 96-well plates. Clones were lysed for 1 hour at 60°C in Kawasaki-buffer (20 mM TrisHCl pH 8.3, 25 mM KCl, 1.5 mM MgCl₂ and 0.5 % Tween) supplemented with proteinase K (2 µg/ml), subsequently incubated at 95°C for 30 minutes and used for screening the chromosomal DNA for homologous integration of the targeting construct by PCR. For this purpose the following primers were used:

P1: 5'- TGT GAC TCG AAG AGA CCC TAA C -3'

P2: 5'- CAG GGT TCA GAG TCC CCT AG -3'

P3: 5'- ACC TGC GTG CAA TCC ATC TTG -3'

This primer set result in a 1.4 kb product in the Wt-allele and a 1.7 kb fragment when the vector has integrated by homologous recombination.

Before blastocyst injection, the Neo cassette was excised by transiently transfecting targeted ES cells with a Cre recombinase expressing construct. Loss of the Neo cassette but not exon 2 was monitored by PCR using the following primers:

P4: 5'- ATC TAG CTG ATC CAT ACT GGG -3'

P5: 5'- AGG TTC TCC CTG GAG TTT GTG TGA -3'

These primers amplified a 1.1 kb fragment in the Wt and a 1.2 kb fragment in the targeted allele when the Neo cassette was excised properly. Subsequent genotyping of conditional TTP knockout animals was done using the same primers.

Two positive clones were injected into C57Bl/6 blastocysts and used to generate chimeric mice. Male chimeric mice were mated to C57Bl/6 females and heterozygote offspring were further backcrossed with C57Bl6 to get C57Bl6 background using speed congenics.

5.4 Construction of Targeting Vector and Generation of Conditional TTP Knockin Mice

For conditional overexpression of TTP, cDNA of murine TTP was amplified by PCR using the following primers carrying Ascl restriction sites (Ascl sites are underlined):

TTP^{high} fw: 5'- TTA CTG TGG GC GCG CCC GGT CTC TTC ACC AAG GC -3'

TTP^{high} rv: 5'- TGC AAG CGG CGC GCC ATC TAG CTG ATC CAT ACT GG -3'

The resulting product was cloned into the Ascl site of a modified pBR322 vector kindly provided by Dr. Robert Eferl. The construct is designed so that TTP is under the control of the human UbiC promoter (ubiquitin C promoter was shown to confer ubiquitous expression in transgenic mice [150]) with a floxed Neo+transcriptional STOP cassette inserted between the UbiC promoter and the cDNA of TTP. The transcriptional STOP cassette consists out of

three SV-40 poly-A sites and efficiently impairs read-through from the UbiC promoter. In addition, an enhanced cyan fluorescent protein (ECFP) is located after the TTP cDNA on the same transcript whose translation is driven by an IRES. Regions homologous to the collagen locus are located at both sides of the construct allowing homologue recombination to this site.

The vector was linearized by NotI digestion and electroporated into 129/OlaHsd embryonic stem cells using an Amaxa Nucleofector Kit according to the manufacturer's protocol. Single cell clones were selected for Neo resistance, isolated for further cultivation on 96-well plates and chromosomal DNA was screened by PCR for homologous integration as described before using the following primers:

P6: 5'- CCC CCT GAA CCT GAA ACA TA -3'

P7: 5'- ACG GGG AGA CAC ATT TCA AG -3'

P8: 5'-GCC ATC CCA ACA ATA CAT CAC A -3'

The primers result in a 1.6 kb fragment for the Wt and a 1.9 kb fragment for the correctly inserted construct.

Two positive clones were injected into C57Bl/6 blastocysts and used to generate chimeric mice. Male chimeric mice were mated to C57Bl/6 females and heterozygote offspring were further crossed to C57Bl/6 mice to obtain C57Bl/6 background using speed congenics as before.

5.5 RNA Analysis

5.5.1 RNA purification

Total RNA was isolated using Trizol LS reagent (Invitrogen) according to the manufacturer's instruction. RNA was quantified using Nanodrop (Peqlab) and visualized by gel electrophoresis before subsequent cDNA preparation or Microarray analysis.

5.5.2 Quantitative RT-PCR

For quantitative RT-PCR (qRT-PCR), total RNA was reverse transcribed using Mu-MLV reverse transcriptase (Fermentas) according to the manufacturer's protocol. qRT-PCR was then performed detecting the fluorescent dye SYBR Green (Molecular Probes) using a Master Cycler (Eppendorf). For *Dusp1* and *Bcl3* qRT-PCR we used the primer sets QT00288638 and QT01164611 from Qiagen (Duesseldorf, DE), respectively. For the PCR amplification of *TTP* mRNA as well as the housekeeping gene *HPRT* for normalization the following primers were used:

For *TTP*:

TTP forward: 5'- CTC TGC CAT CTA CGA GAG CC - 3'

TTP reverse: 5'- GAT GGA GTC CGA GTT TAT GTT CC- 3'

For *HPRT*:

HPRT forward: 5'- GGA TTT GAA TCA CGT TTG TGT CAT - 3'

HPRT forward: 5'- ACA CCT GCT AAT TTT ACT GGC AA - 3'

5.6 Protein Analysis

5.6.1 ELISA

For Enzyme-linked immunosorbent assay (ELISA), primary macrophages were seeded the day before (2×10^6 cells per 6 cm dish). Supernatant of LPS stimulated cells was collected and diluted 1:5 in reagent diluent. TNF α was then assayed using DuoSET ELISA kits (R&D Systems, Minneapolis, MN).

5.6.2 Western Blot

Western blot analysis was performed as described [151] using whole cell lysates from 2×10^6 cells seeded on 6 cm plates the day before. Cells were treated as indicated and assayed using fluorophore-linked secondary antibodies (Molecular Probes-Invitrogen (Lofer, Austria) and Rockland (Gilbertsville, PA)) and an Odyssey infrared imaging system (LI-COR Bioscience, Lincoln, NE).

5.7 Animal models

5.7.1 LPS-induced shock model

LPS challenge was performed with age-matched (8 weeks) mouse groups for Wt (comprising Wt or TTP^{fl/fl}, n=10) and TTP^{fl/fl} LysMCre mice (n=12) on a mixed background. LPS at a concentration of 62.5 mg/kg body weight dissolved in 0.9% NaCl was injected intraperitoneally and mice were monitored for time of death to calculate a Kaplan-Meier blot. All animal experiments were carried out in accordance with protocols approved by the Austrian Laws (GZ68.205/67-BrGZ/2003) and European Directives.

5.7.2 B-cell lymphoma formation

2x10⁶ cells of Abelson-transformed Wt or TTP^{-/-} B-cell lines (CD19⁺/CD43⁺/B220⁺) were injected subcutaneously into the hind leg of age-matched C57Bl/6 mice (8 weeks). At the time of injection, cells were grown for at least a week in growth factor-free medium. Tumors were isolated 10 days later to determine tumor size and weight. Transformed B-cell lines from bone marrow of 3 individual Wt and 4 TTP^{-/-} mice were injected into 4 animals each.

6. RESULTS

In this thesis the regulation and function of TTP in inflammation and cancer development *in vitro* and *in vivo* will be addressed in the following four topics:

i) The role of TTP as an effector of the IL-10-mediated anti-inflammatory response in LPS-treated macrophages published by Schaljo B. et al. 2009 (Schaljo B. and Kratochvill F. contributed equally to this work) [30]. My contribution to this study was to show that IL-10 signaling leads to decreased TTP phosphorylation and subsequent increased TTP binding and decay of *Tnf* and *IL-1 α* mRNA.

ii) The qualitative and temporal regulation of mRNA decay during inflammation by TTP and p38 MAPK (Kratochvill F. et al., manuscript submitted).

In this study we revealed a TTP and p38 MAPK dependent negative feedback loop that governs the mRNA decay of a broad set of inflammation induced genes.

iii) The generation of conventional TTP knockout as well as knockin mice and the role of myeloid TTP in an animal model of acute inflammation.

In order to dissect the role of TTP in various disease models we created a conditional TTP knockout mouse and confirmed its utility in a model of endotoxic shock.

iv) The role of TTP in *v-abl* induced B-cell lymphoma formation.

We investigated the contribution of TTP in *v-abl* induce transformation of murine bone marrow into growth factor independent cell lines and subsequent tumor formation *in vivo*.

IL-10 is essential for inhibiting chronic and acute inflammation by decreasing the amounts of proinflammatory cytokines made by activated macrophages. IL-10 controls proinflammatory cytokine and chemokine production indirectly via the transcription factor Stat3. One of the most physiologically significant IL-10 targets is TNF- α , a potent proinflammatory mediator that is the target for multiple anti-TNF- α clinical strategies in Crohn's disease and rheumatoid arthritis. The anti-inflammatory effects of IL-10 seem to be mediated by several incompletely understood transcriptional and posttranscriptional mechanisms. In this study, we show that in LPS-activated bone marrow-derived murine macrophages, IL-10 reduces the mRNA and protein levels of TNF- α and IL-1 α in part through the RNA destabilizing factor tristetraprolin (TTP). TTP is known for its central role in destabilizing mRNA molecules containing class II AU-rich elements in 3' untranslated regions. We found that IL-10 initiates a Stat3-dependent increase of TTP expression accompanied by a delayed decrease of p38 MAPK activity. The reduction of p38 MAPK activity releases TTP from the p38 MAPK-mediated inhibition, thereby resulting in diminished mRNA and protein levels of proinflammatory cytokines. These findings establish that TTP is required for full responses of bone marrow-derived murine macrophages to IL-10. *The Journal of Immunology*, 2009, 183: 0000–0000.

One of the key players in immune homeostasis is IL-10, a cytokine that was discovered 18 years ago as a T cell-secreted factor that inhibited cytokine production by Th1 cells (1). Over the years, it became clear that IL-10 is produced by many cell types including T and B cells, macrophages, dendritic cells, mast cells, keratinocytes, or epithelial cells (2). It is generally considered that the main biological function of IL-10 is to limit or shut down inflammatory responses. This notion is supported by the phenotype of IL-10-deficient mice that develop severe inflammatory bowel disease due to spontaneous chronic inflammation and are susceptible to endotoxin treatment because of acute overpro

duction of proinflammatory cytokines (3, 4). Many of these phenotypes can be recapitulated by T cell-specific deletion of the IL-10 gene, indicating that T cell-derived IL-10 is primarily responsible for chronic inflammation (5). Under conditions of acute inflammation, the main source of IL-10 are macrophages and dendritic cells (6). On the cellular level, IL-10 inhibits production of proinflammatory cytokines and regulates differentiation and proliferation of various immune cells. These effects depend entirely on the activation of the transcription factor Stat3 by IL-10 (7–11). The events downstream of Stat3 activation that mediate the anti-inflammatory functions of IL-10 remain an area of active research. It is becoming increasingly clear that multiple mechanisms mediate the IL-10 function. On the one hand, IL-10 inhibits transcription of a subset of proinflammatory genes (12, 13). In a mouse model lacking 3' untranslated regions (UTR) in the *Tnf* gene, the transcriptional mechanism was found to play a major role in IL-10 responses (13). On the other hand, IL-10 was also reported to act

posttranscriptionally by increasing the rate of mRNA decay of inflammatory cytokines such as TNF- α or by inhibiting translation (12, 14, 15). The posttranscriptional regulation depends on 3' UTR containing AU-rich elements (AREs) (16). However, far less is known about the IL-10-regulated effector genes that control the anti-inflammatory response. Several candidates have been described, but so far none have been shown to account for the majority of the anti-inflammatory effects (17). IL-10 was also demonstrated to up-regulate the dual-specificity phosphatase 1 (DUSP1) in LPS-stimulated macrophages, causing a more rapid inactivation of p38 MAPK (18). The reduction of p38 MAPK activity may lead to a decreased stability of ARE-containing mRNAs and/or reduced transcription by transcription factors that depend on p38 MAPK. Recently, the transcriptional repressor ETV3 and

the corepressor SBNO2 were characterized as IL-10/Stat3-induced genes that may contribute to the anti-inflammatory IL-10 effects (19). An important aspect of the above-mentioned studies that remains to be resolved is how IL-10 inhibits specifically only a subset of inflammatory genes. These studies indicate that yet unknown IL-10/Stat3 target genes need to be discovered to complement the current knowledge about the anti-inflammatory effects of IL-10.

In this study, we demonstrate that IL-10-mediated reduction of TNF- α and IL-1 α production by LPS-treated mouse bone marrow-derived macrophages (BMDMs) is less efficient in cells lacking the RNA-destabilizing factor tristetraprolin (TTP). TTP is known to bind and destabilize mRNAs of several proinflammatory cytokines (e.g., TNF- α) containing class II AREs in their 3' UTRs (20). TTP facilitates degradation of the bound mRNA by initiating the assembly of RNA decay machinery (21, 22). The RNA degradation activity of TTP is negatively regulated by p38 MAPK-dependent signaling (23–25). Mice lacking TTP (encoded by the *Zfp36* gene) develop multiple chronic inflammatory syndromes ranging from arthritis to cachexia to dermatitis that can all be relieved by reduction of TNF- α levels (26). By comparing LPS-treated wildtype and TTP-deficient BMDMs, we show that IL-10 accelerates, in a TTP-dependent way, the decay of TNF- α mRNA, resulting in a reduction of secreted TNF- α . Furthermore, IL-10 increases TTP expression in LPS-treated wild-type (WT) but not Stat3-deficient BMDMs. However, we show that the increased TTP levels are not sufficient to mediate the IL-10 effects. Instead, the IL-10-mediated reduction of p38 MAPK activity in LPS-treated BMDMs that is known to be caused by up-regulation of the p38 MAPK phosphatase DUSP1 (18) is required to act in concert with TTP to reduce mRNA levels of proinflammatory cytokines such as TNF- α and IL-1 α . We propose that the sustained activation of Stat3 by IL-10 causes both an increased TTP expression and a reduction in p38 MAPK activity. The combination of these effects results in a reduction of mRNA stability and attenuation of cytokine production.

Materials and Methods

Reagents

Stat3, p38 MAPK, and DUSP1 (sc-1102) Abs were from Santa Cruz Biotechnology, the ERK Ab was from BD Transduction Laboratories, and the phosphotyrosine-Stat3 Ab (pY-Stat3) was from Cell Signaling and New England Biolabs. Rabbit Ab to TTP was obtained by immunizing rabbits with 44 C-terminal amino acids of TTP fused to GST. IL-10 and IL-6 (Sigma-Aldrich) were used at a concentration of 10 ng/ml, LPS from *Salmonella minnesota* (Alexis) was used at a concentration of 5–10 ng/ml, and anisomycin and actinomycin D (both Sigma-Aldrich) were used at a concentration of 100 ng/ml and 5 μ g/ml, respectively. SB203580 (SB; Sigma-Aldrich) was dissolved in DMSO and used at final concentration 4 μ M. ATP (1 μ M; Sigma-Aldrich) was added 1 h before collecting the samples.

Cell culture

Primary macrophages were grown in L cell-derived CSF-1 as previously described (27). *Zfp36* and *Dusp1* mice (26) were on the C57BL/6 background. The *Zfp36* gene encodes TTP, which is the better known name and therefore is used throughout. For experiments with cells derived from TTP and TTP^{fl/fl} mice, littermates originating from the TTP^{fl/fl} colony were used. The *LysMcre-Stat3^{fl/fl}* mice were obtained by crossing Stat3^{fl/fl} mice (28) with *LysMcre*, strain B6.129P2-*Lyz2^{cre}* (The Jackson Laboratory), all on the C57BL/6 background. Mice, 8–12 wk old at the time of bone marrow collection, were housed under specific pathogen-free conditions. Mouse experiments were conducted in compliance with national laws. Mouse macrophage line RAW 264.7 was grown in DMEM supplemented with 10% FCS.

Inducible expression of TTP

The open reading frame of the mouse TTP was PCR-amplified from cDNA. The PCR was used to add Flag tag DYKDDDDK at the C terminus. The TTP-Flag fragment was cloned into the pGL2-basic (Promega) containing a tetracycline-responsive element (TRE) in the promoter. The resulting plasmid pTRE-TTPfl was transfected into HeLa-Tet-off cells (BD Clontech) using nucleofection (Amaxa). After transfection, the cells were incubated overnight in medium with (no TTP expression) or without (TTP expression) tetracycline (1 μ g/ml).

ELISA

For ELISA, BMDMs were seeded the day before use at 2×10^5 cells/well in a 24-well plate. Supernatants were diluted 1/8 in DMEM (for TNF- α) or 1/2 (for IL-1 α) and cytokines were assayed using ELISA kits (R&D Systems) according to the manufacturer's instructions.

Quantitative Western blot

After treatment, whole cell extracts were prepared and assayed by Western blotting as described elsewhere (29). Detection and quantitation of signals were performed using the infrared imaging system Odyssey (LI-COR Biosciences).

Quantitation of gene expression by quantitative RT-PCR (qRT-PCR)

Total RNA was isolated using TRIzol reagent (Invitrogen). Reverse transcription was performed with Moloney murine leukemia virus reverse transcriptase (Fermentas). The following primers were used: for HPRT, the housekeeping gene used for normalization, HPRT forward (fwd) 5'-GG ATTTGAATCACGTTTGTGTCAT-3' and HPRT reverse (rev) 5'-ACAC CTGCTAATTTACTGGCAA-3'; for TTP, TTP fwd 5'-CTCTGCCATC TACGAGAGCC-3' and TTP rev 5'-GATGGAGTCCGAGTTTATGTTT C-3'; for TNF- α , TNF- α fwd 5'-CAAATTCGAGTGACAAGCCTG-3' and TNF- α rev 5'-GAGATCCATGCCGTTGGC-3'; for suppressor of cytokine signaling (SOCS) 3, SOCS3 fwd 5'-GCTCCAAAAGCGAGTACC AGC-3' and SOCS3 rev 5'-AGTAGAATCCGCTCTCCTGCAG-3'; and for TTP primary transcript, TTPpt fwd 5'-GACTGCAAGCTCGTGAA GT-3', pt-TTP rev 5'-CAGTCAGGCGAGAGGTGA-3'. For determination of mRNA decay by qRT-PCR, the primers TNF- α fwd 5'-TTCTGT CTAAGAACTTCGGGGTGATCGGTCC-3' and TNF- α rev 5'-GTAT GAGATAGCAAATCGGCTGACGGTGTGGG-3' and for IL-1 α , the primer set QT00113505 from Qiagen was used. Amplification of DNA was monitored by SYBR Green (Molecular Probes) (30).

RNA EMSA

To prepare extracts, cells were washed with cold PBS and lysed in buffer containing 10 mM Tris-HCl (pH 7.5), 50 mM NaCl, 30 mM NaPP₆, 50 mM NaF, 2 mM EDTA, 1% Triton X-100, and a protease inhibitor mixture (Roche). Extracts were cleared by centrifugation at 15,000 rpm. Twelve-microliter cell extracts (30 μ g of protein) from RAW 264.7 cells or 5-1 cell extracts (15 μ g of protein) from pTRE-TTPfl-transfected HeLa-Tet-off cells were incubated with 0.5 μ l of poly(U) RNA (100 ng/ μ l), 0.5 μ l of Cy5.5-labeled TNF- α ARE (1 pmol/ μ l), 1 μ l of RiboLock RNase Inhibitor (Fermentas), and 2.5 μ l of 5x Gelshift buffer (200 mM KCl, 5 mM MgCl₂, 0.5 mM EGTA, 2.5 mM DTT, 100 mM HEPES-KOH (pH 7.9), and glycerol 50% (v/v)) for 20 min at room temperature. For supershift assays, 0.5 μ l of TTP antiserum was added. Samples were then separated on a 6% polyacrylamide gel. The Cy5.5 signal was detected and quantified using the infrared imaging system Odyssey (LI-COR Biosciences). Poly(U) RNA and Cy5.5-labeled TNF- α ARE RNA were purchased from Microsynth. The sequence for Cy5.5-labeled TNF- α ARE was as follows: 5'-AUUAUUUAUUUAUUUAUUUAUUUA-3'.

Statistical analysis

Data from independent experiments were analyzed using univariate linear regression models and the SPSS program. For qRT-PCR normalized copy numbers and for ELISA pg/ml were log-transformed. Residuals were plotted, visually inspected, and tested for normality. Design matrices were specified such that the coefficients for the relevant comparisons could be calculated, e.g., between the baseline and induced states and between genotypes. Only the significance levels are reported.

Results

IL-10 increases TTP expression in LPS-treated macrophages in a Stat3-dependent manner

TTP expression has been reported to be controlled by the transcription factors Stat1 (in response to IFNs) and Stat6 (in response to IL-4) (27, 31). Affymetrix analysis revealed that LPS-induced TTP expression is further enhanced by IL-10 (data not shown) at

FIGURE 1. IL-10-mediated increase of TTP expression in LPS-treated macrophages depends on Stat3. **A**, BMDMs from LysMcre-Stat3 (LysM-Stat3) and LysMcre-Stat3^{fl/fl} (LysM-Stat3fl/fl) mice were treated for 1 h with LPS (L), IL-10, or both (IL-10/L). Induction of TTP mRNA was quantified using qRT-PCR. Bars indicate SDs, $n = 3$. **B**, BMDMs from LysMcre-Stat3 (LysM-Stat3) and LysMcre-Stat3^{fl/fl} (LysM-Stat3fl/fl) animals were left untreated or treated with IL-10 (IL), LPS (L), or both (IL/L) for 3 h. TTP protein levels were analyzed by Western blotting of cell extracts using TTP Ab. TTP appears in multiple bands representing phosphorylated forms. Blot was reprobed with Stat3 Ab to control for Stat3 deletion in LysMcre-Stat3^{fl/fl} cells and panERK Ab for loading control. Differences in TTP levels (normalized to panERK and quantitated using infrared imaging system Odyssey) in cells treated with IL-10/LPS compared with LPS alone are indicated. **C**, BMDM (WT) were stimulated for 30 min with LPS (L), IL-10, or both (IL-10/L), total RNA was isolated, DNase treated, and the amount of primary transcript was determined by qRT-PCR. Bars indicate SDs, $n = 3$.

30 min after treatment of IL10⁺ BMDMs with IL-10 and LPS, suggesting that TTP may represent a Stat3 target gene involved in the anti-inflammatory responses to IL-10. To examine the effect of IL-10 on TTP expression in more detail, we investigated TTP gene expression in BMDMs conditionally deleted for Stat3 (LysMcreStat3^{fl/fl}) and control LysMcre-Stat3 cells. LysMcre is known to delete loxP-flanked alleles in macrophage and

neutrophil lineages with >90% efficiency (7). Treatment of BMDMs with IL-10 and LPS caused a 2- to 3-fold increase in TTP mRNA (Fig. 1A) and protein levels (Fig. 1B) compared with LPS treatment alone. The IL-10-mediated increase in TTP expression required Stat3 since in LysMcre-Stat3^{fl/fl} cells the TTP levels remained unchanged upon IL-10 treatment. The expression of Stat3 was reduced by >90% in LysMcre-Stat3^{fl/fl} cells (Fig. 1B), thereby confirming the deletion efficiency by LysMcre. Analysis of TTP primary transcripts by PCR (Fig. 1C) and nuclear run-on assays (data not shown) revealed that the IL-10-mediated induction of TTP was caused by increased transcription.

These findings document that IL-10-activated Stat3 increases expression of TTP in LPS-stimulated macrophages. IL-10 alone only weakly increased TTP transcription, and this induction was not sufficient to generate detectable levels of TTP protein. This way of regulation resembles that of IFN-induced TTP expression, which was shown to be activated by IFNs and the IFN-activated Stat1 only if p38 MAPK signaling (by e.g., LPS) is stimulated in parallel (27). p38 MAPK is known to increase by yet unclear mechanisms the transcriptional activity of several Stat members (32–34).

TTP is required for full inhibitory effect of IL-10 on TNF- α and IL-1 α production

To test whether TTP was an effector of the IL-10 anti-inflammatory responses, we measured the amount of secreted TNF- α by ELISA in BMDMs from TTP^{fl/fl} and control WT littermates that were treated with LPS with or without pretreatment with IL-10. We measured TNF- α production at 6, 8, and 10 h after LPS stimulation. After 10 h, TNF- α was diminished by IL-10 to

♦20% in control cells, whereas in TTP^{fl/fl} cells only a reduction to 60% was achieved (Fig. 2A). Similar results were obtained if cells were treated simultaneously with LPS and IL-10 (Fig. 2B), although the contribution of TTP to the IL-10 response was higher in the pretreatment protocol (Fig. 2A).

These data show that TTP contributes to IL-10-mediated inhibition of TNF- α cytokine production.

To investigate whether the incomplete IL-10-mediated inhibition of TNF- α production in TTP^{fl/fl} BMDMs resulted from differences in mRNA amounts or in mRNA decay, we analyzed the amounts of TNF- α mRNA in LPS-stimulated TTP^{fl/fl} and control BMDMs with or without pretreatment with IL-10. In WT cells, IL-10 caused a reduction of TNF- α mRNA to 40% of the amount present in cells treated with LPS alone, whereas in TTP^{fl/fl} cells IL-10 caused a reduction to only 80% of the level in cells treated with LPS alone (Fig. 2C). In these experiments, TNF- α mRNA was measured after 2 h of LPS treatment since the amount of TNF- α mRNA peaks at this time point (Ref. 13 and data not shown). To further illustrate the role of TTP in IL-10-mediated decrease of TNF- α mRNA, we analyzed the rate of TNF- α mRNA decay in LPS-stimulated TTP^{fl/fl} and WT BMDMs with or without IL-10 pretreatment. Transcription was stopped after 3 h of LPS stimulation by addition of actinomycin D, and the degradation of TNF- α mRNA was followed in 15-min intervals for a total of 45 min after imposing the transcriptional stop (Fig. 3A). In LPS-treated control BMDMs, the decay rate of TNF- α mRNA was increased 2.5-fold by IL-10 treatment (half-life $t_{1/2}$ without IL-10 = 32 min; $t_{1/2}$ with IL-10 = 13 min). In LPS-treated TTP^{fl/fl} BMDMs, the residual TNF- α mRNA decayed with a 2.5-fold longer half-life ($t_{1/2}$ = 82 min) compared with WT. This difference is similar to the one reported previously (35). Importantly, IL-10 treatment of LPS-stimulated

TTP⁺ cells did not increase the decay rate and the remnant mRNA levels were comparable to those in cells treated with LPS alone. LPS-stimulated macrophages produced endogenous IL-10 that is known to mask to some extent the effect of added IL-10 (see Ref. 18). Since TTP was recently

FIGURE 2. TTP is required for full IL-10-mediated inhibition of TNF- α

production. **A**, Reduction of LPS-induced TNF- α cytokine production in cells pretreated with IL-10. BMDMs from WT and TTP $^{-/-}$ mice were treated with LPS or pretreated overnight (o/n) with IL-10 followed by stimulation with LPS (ILon/LPS) for indicated time points. Supernatants were collected and analyzed for TNF- α cytokine levels by ELISA. Reduction of TNF- α cytokine levels by IL-10 pretreatment (IL-10 o/n) relative (in percent) to LPS-alone treatment (100%) is depicted. SDs ($n = 4$) are indicated. **B**, Effect of simultaneous treatment with IL-10 and LPS on TNF- α cytokine production performed as described in **A**. Relative amounts of TNF- α cytokine secreted by LPS-treated WT and TTP $^{-/-}$ BMDMs compared with cells simultaneously treated with IL-10/LPS are shown. SDs ($n = 3$) are indicated. **C**, Reduction of LPS-induced TNF- α mRNA in cells pretreated with IL-10. WT-BMDMs and TTP-deficient BMDMs (TTP $^{-/-}$) were treated 2 h with LPS or pretreated overnight with IL-10 followed by LPS addition (IL-10/L) and analyzed for expression of TNF- α by qRT-PCR, normalized to HPRT mRNA. Shown is the reduction of

TNF- α mRNA levels after IL-10/LPS treatment in relation to the sample treated with LPS alone. SDs ($n = 3$) are indicated.

shown to target IL-10 mRNA for degradation (36), we asked whether TTP $^{-/-}$ BMDMs produce more IL-10 after stimulation with LPS. Cytokine measurement revealed that TTP-deficient cells secrete 2- to 3-fold more IL-10 than the WT cells (supplemental Fig. S1³). To assess the contribution of endogenous IL-10 to the IL-10-mediated TNF- α mRNA decay, we compared the TNF- α mRNA levels and decay rates in IL-10 $^{-/-}$ and WT cells. IL-10 $^{-/-}$ BMDMs expressed 2-fold more TNF- α than WT cells (Fig. 3B). Importantly, the reduction of TNF- α mRNA by exogenous IL-10 was more pronounced in IL-10 $^{-/-}$ cells compared with WT cells. The decay rate of TNF- α mRNA was not affected by IL-10 treatment of WT cells stimulated for 1 or 2 h with LPS (Fig. 3C). However, IL-10 accelerated the decay rate in IL-10 $^{-/-}$ cells treated for 2 h with LPS, but not for 1 h (Fig. 3D). Therefore, endogenous IL-10 can mask to a certain extent the effect of exogenous IL-10 on the mRNA decay. In addition, the IL-10-mediated increase in mRNA decay rate becomes more apparent at later time points of LPS treatment, consistent with the need for new protein synthesis (e.g., TTP). Note that the duration of LPS treatment in Fig. 3A was 3 h and that the differences in IL-10-imposed inhibition of TNF- α production in TTP $^{-/-}$ vs WT cells increased with time of LPS treatment (Fig. 2, A and B).

To further substantiate the role of TTP in the anti-inflammatory effects of IL-10, we measured the IL-10-mediated reduction of IL-1 α protein and mRNA in TTP $^{-/-}$ and WT cells (Fig. 3, E and F). Efficient LPS-stimulated production of IL-1 α , a known IL-10 target (13), depends on a second stimulus, such as ATP, that activates the IL-1-processing function of the inflammasome (37). Although IL-1 α is not a direct substrate of caspase 1, production of mature IL-1 α has been shown to be inflammasome/caspase 1 dependent (37). BMDMs from WT and TTP $^{-/-}$ animals were stimulated with LPS (10 h) and ATP (1 h before the collection of supernatants) in the presence or absence of IL-10. IL-10 caused a decrease of IL-1 α protein to 20% of LPS plus ATP-treated WT cells, whereas in TTP $^{-/-}$ cells the IL-1 α production was reduced only to 60% of the LPS plus ATP-treated samples (Fig. 3E). Similar differences between WT and TTP $^{-/-}$ cells were determined also for the IL-10-mediated decrease in IL-1 α mRNA (Fig. 3F).

To rule out that the absence of TTP affected activation of Stat3 by IL-10 that might result in reduced IL-10 responsiveness of TTP $^{-/-}$ cells, the IL-10-induced tyrosine phosphorylation of Stat3 was determined in LPS-stimulated TTP $^{-/-}$ and WT BMDMs in the presence or absence of IL-10. The level of tyrosine-phosphorylated Stat3 was under all conditions comparable in both genotypes (supplemental Fig. S2A). In addition, the stimulatory effect of LPS was similar in TTP $^{-/-}$ and WT cells as judged by the activation of p38 MAPK (supplemental Fig. S2B). Thus, a different activation of the critical proinflammatory (p38 MAPK) and anti-inflammatory (Stat3) components in the WT and TTP $^{-/-}$ cells could be excluded as a reason for the observed differences in IL-10 responses. These data establish that TTP plays an important role in IL-10-mediated down-regulation of two critical inflammatory cytokines (TNF- α and IL-1 α).

TTP function in IL-10 responses depends on IL-10-mediated reduction of p38 MAPK activity at later phase of inflammation

IL-10 and IL-6 are both known to activate Stat3 yet only IL-10 exhibits anti-inflammatory properties (38–40). To examine whether and to what extent IL-6 was able to stimulate TTP expression, BMDMs were treated with LPS with or without IL-6.

¹The online version of this article contains supplemental material.

FIGURE 3. TTP is required for IL-10-mediated acceleration of TNF- α mRNA decay and for full IL-10-dependent reduction of IL-1 α . *A*, IL-10-induced changes in decay of TNF- α mRNA. WT-BMDMs and TTP-deficient BMDMs (TTP^{-/-}) were pretreated with IL-10 overnight and stimulated for 3 h with LPS followed by addition of actinomycin D (act D; 5 μ g/ml) to stop transcription. After the indicated time points, TNF- α mRNA was quantified using qRT-PCR. Values were normalized against the housekeeping gene HPRT. Remnant TNF- α mRNA in percentage of the amount at the time point 0 of actinomycin D treatment is depicted. SDs ($n = 3$) are indicated. *B*, Effects of endogenous IL-10 on TNF- α mRNA induction in LPS- or LPS/IL-10-treated BMDMs. BMDMs derived from WT or IL-10 animals were treated for 1 or 2 h with LPS in the presence or absence of IL-10. The amount of TNF- α mRNA in these cells was determined by qRT-PCR. *C* and *D*, TNF- α mRNA decay in WT (*C*) and IL-10^{-/-} (*D*) BMDMs. BMDMs were treated for 1 or 2 h with LPS in the presence or absence of IL-10. Thereafter, the transcription was stopped by actinomycin D and the remaining TNF- α mRNA was determined at the indicated times by qRT-PCR. Remnant TNF- α mRNA in percentage of the amount at the time point 0 of actinomycin D treatment is depicted. *E*, Reduction of IL-1 α cytokine by IL-10. BMDMs from WT and TTP^{-/-} mice were treated with LPS for 10 h in the presence or absence of IL-10. ATP was added 1 h before the collection of supernatants. Supernatants were collected and analyzed for IL-1 α cytokine levels by ELISA. Reduction of IL-1 α cytokine levels by IL-10 pretreatment relative (in percent) to LPS alone treatment (100%) is depicted. SDs are indicated, $n = 3$. *F*, Reduction of IL-1 α mRNA by IL-10. BMDMs from WT and TTP^{-/-} mice were treated with LPS for 2 h in the presence or absence of IL-10. IL-1 α expression was analyzed by qRT-PCR. Reduction of IL-1 α mRNA by IL-10 treatment relative (in percent) to LPS alone treatment (100%) is depicted.

Interestingly, IL-6 was able to increase TTP expression in LPS-treated macrophages almost to the same extent as IL-10 (Fig. 4A). Yet, consistent with the known properties of IL-6, IL-6 was not able to inhibit TNF- α (Fig. 4B) and IL-1 α (Fig. 4C) in either WT or TTP^{-/-} BMDMs. These data also implicate that the up-regulation of TTP expression by IL-10 cannot solely explain the role of TTP in the anti-inflammatory effects of this cytokine. We speculated that the role of TTP in IL-10 responses might be explained by an IL-10-dependent increase in TTP activity. TTP function is known to be negatively regulated by p38 MAPK and its downstream kinase MK2 (41). IL-10 has been reported to modestly inhibit p38 MAPK in the later phases of LPS treatment (18). The reduction of p38 MAPK activity is caused by the IL-10-mediated up-regulation of the dual-specificity phosphatase DUSP1 (Ref. 18 and Fig. 4F). We reasoned that such a reduction in p38 MAPK could relieve the p38 MAPK-dependent inhibition of TTP, thereby increasing the ability of TTP to down-regulate its target mRNAs. To investigate whether IL-6 was also able to reduce p38 MAPK activity, BMDMs were stimulated with LPS alone or along with either IL-10 or IL-6 and p38 MAPK activity was monitored after 2, 4, and 6 h. Treatment of LPS-stimulated cells with IL-10 caused a modest (3-fold) but consistent inhibition of p38 MAPK at 2, 4, and 6 h compared with the samples treated with LPS alone (Fig. 4D). To better document the IL-10 effect on p38 MAPK phosphorylation, the complete time course of IL-6- and IL-10-treated samples was run on a single gel

(supplemental Fig. S3A). The LPS-induced activation of p38 MAPK at an early time point (30 min) was not affected by IL-10 cotreatment (Fig. 4E). Importantly,

FIGURE 4. Effects of IL-6 on TTP expression, TNF- α and IL-1 α production, and p38 MAPK activation in LPS-treated BMDMs. *A*, IL-6 and IL-10 increase

TTP expression to similar levels in LPS-treated BMDMs. BMDMs were stimulated for 2 h with LPS alone or along with IL-10 or IL-6, and whole cell extracts were prepared. Expression of TTP was analyzed by Western blotting. panERK Ab was used for loading control. *B* and *C*, IL-6 does not reduce TNF- α production (*B*) or IL-1 α (*C*) production in LPS-treated TTP $^{-/-}$ and control WT BMDMs. WT and TTP $^{-/-}$ BMDMs were stimulated for 10 h with LPS with or without cotreatment with IL-6. Amounts of TNF- α and IL-1 α in supernatants were determined by ELISA. SDs of three representative experiments ($n = 3$) are indicated. *D*, IL-10 but not IL-6 decreases p38 MAPK activity in LPS-treated BMDMs. Whole cell extracts of BMDMs treated for 2, 4, and 6 h with LPS alone or cotreated with IL-10 or IL-6 were analyzed for activation of p38 MAPK by Western blotting using Ab to activated p38 MAPK (pp38). Ab to total p38 MAPK (p38) was used for loading control. *E*, p38 MAPK is not inhibited by IL-10 or IL-6 after 30 min of treatment. BMDMs were treated for 30 min with LPS with or without cotreatment with IL-10 or IL-6. p38 MAPK activation was determined as in *D*. *F*, IL-10 no longer reduces p38 MAPK phosphorylation in DUSP1 $^{-/-}$ BMDMs. DUSP1 $^{-/-}$ BMDMs were treated for 4 h with LPS alone, LPS + IL-10 or LPS + IL-6, and the activation of p38 MAPK was examined as in *D*. Figures are representative of at least three experiments.

p38 MAPK activity was not reduced by treatment with IL-6 at any time point examined (Fig. 4, *D* and *E*, and supplemental Fig. S3A). These findings are in agreement with the induction of mRNA for the MAPK phosphatase DUSP1 by IL-10 but not IL-6 in LPS-treated macrophages (18). To further support the role of DUSP1 in the IL-10-mediated effect on p38 MAPK activity, we examined p38 MAPK phosphorylation in DUSP1 $^{-/-}$ BMDMs treated with LPS alone or along with either IL-10 or IL-6 for 4 h. In DUSP1 $^{-/-}$ cells, IL-10 was no longer able to reduce p38 MAPK phosphorylation after treatment (Fig. 4*F*). Consistent with the IL-10-mediated decrease in p38 MAPK phosphorylation, at the 4 h-time point, the induction of DUSP1 by IL-10 plus LPS compared with LPS alone was more apparent than after a shorter treatment (1 h; supplemental Fig. S3B). The different effect of IL-10 and IL-6 on p38 MAPK is in agreement with the anti-inflammatory properties that are exhibited by IL-10 but not IL-6. The difference between IL-10 and IL-6 with regard to their anti-inflammatory properties has been attributed to SOCS3 that, as part of the negative feedback loop, binds to the gp130 subunit of the IL-6 receptor but not to the IL-10 receptor (38–40). Thus, SOCS3, a Stat3 target gene, is able to inhibit signaling elicited by IL-6 but not by IL-10. Consequently, IL-10 induces a prolonged Stat3 activation, whereas IL-6-mediated Stat3 activation is rapidly shut down. Consistently, in LPS-treated BMDMs IL-10 and IL-6 caused a comparable Stat3 activation after 30 min of cytokine treatment, whereas after 2 h Stat3 remained active only in cells stimulated with IL-10 but not IL-6 (supplemental Fig. 3C). These data suggest that a sustained Stat3 activation is needed for inhibition of p38 MAPK.

Although p38 MAPK is needed for TTP expression and protein stability (24, 25, 42), the kinase negatively regulates TTP activity at least at two levels. First, phosphorylation of TTP at Ser⁵² and Ser⁷⁸ by MAPK-activated protein kinase 2 (MK2), a kinase downstream of p38 MAPK, provides binding sites for 14-3-3 proteins that reduce the destabilizing activity of TTP (23, 43). Second, phosphorylation of TTP by MK2 was reported to negatively regulate its binding to AREs (25). To show that the IL-10-mediated decrease in p38 MAPK activity was able to change TTP properties in terms of its phosphorylation and binding to AREs, we analyzed the mobility of TTP in SDS-PAGE and binding of TTP to AREs in EMSA experiments. TTP appears in SDS-PAGE in the form of multiple bands that reflect various degree of predominantly p38 MAPK-dependent phosphorylation (24). To demonstrate p38 MAPK effects on TTP phosphorylation and binding to AREs, we first used an inducible expression of TTP in HeLa-Tet-off cells. This system allows manipulation of p38 MAPK activity without affecting the transcription of the TTP gene that is known to require p38 MAPK activity (27, 42). Stimulation of HeLa-Tet-off cells expressing TTP (i.e., without tetracycline) with anisomycin (a p38 MAPK agonist (44)) resulted in a more pronounced appearance of a slower migrating hyperphosphorylated TTP band, whereas the p38 MAPK inhibitor SB reduced the amount of the hyperphosphorylated TTP and also the total TTP level due to TTP protein destabilization (Fig. 5A). The analysis of

FIGURE 5. IL-10 reduces TTP phosphorylation and increases in vitro binding of TTP to ARE. *A* and *B*, HeLa-Tet-off cells were transiently transfected with

pTRE-TTPfl and equally split into four 6-cm dishes. In three dishes, the expression of TTP was allowed overnight in medium without tetracycline (-Tet), whereas in one dish the TTP expression was blocked by tetracycline (+Tet). The (-Tet) cells were treated for 60 min with anisomycin (aniso) or SB. Whole cell extracts were prepared and split into one part for Western blot analysis (*A*) and a second part for RNA EMSA (*B*). The position of hyperphosphorylated (hyper-p.) and hypophosphorylated (hypo-p.) TTP is marked in *A*, *B*. The TTP-ARE complexes (TTP) were identified by a supershift (ssTTP) using a TTP Ab (aTTP). The relative intensity of the TTP-ARE complexes (as indicated by the numbers 1.5, 1, and 1.4) was quantitated using the LI-COR Odyssey software (supplementary Fig. 4A). *C*, Whole cell extracts of BMDMs treated for 4 and 6 h with LPS alone or cotreated with IL-10 or IL-6 were analyzed for TTP expression and SDS-PAGE mobility by Western blotting using Ab to TTP. Equal protein loading was controlled by reprobing with an anti-ERK Ab. The position of hyperphosphorylated (hyper-p.) and hypophosphorylated (hypo-p.) TTP is marked. *D*, Whole cell extracts of RAW 264.7 treated for 6 h with LPS alone or cotreated with IL-10 or IL-6 were analyzed as in *C*. *E*, Whole cell extracts of RAW 264.7 cells treated for 4 or 6 h with LPS alone or cotreated with IL-10 or IL-6 were assayed for in vitro binding of TTP to TNF- α ARE using RNA EMSA. The relative intensity of the TTP-ARE complexes (as indicated by the numbers 1, 2, 1.3, 1.3, 1.8, and 1.3) was quantitated using the LI-COR Odyssey software (supplementary Fig. 4B). To control the position of the TTP-ARE complexes extracts from HeLa-Tet-off cells expressing TTP (-Tet) or without TTP expression (+Tet) were used. The data are representative of three independent experiments.

the same extracts in a RNA EMSA experiment revealed that anisomycin reduced binding of TTP to the TNF- α ARE by 50% (Fig. 5B), whereas inhibition of p38 MAPK resulted in a similar amount of ARE-bound TTP as in untreated cells (Fig. 5B) despite a reduced TTP protein level present in that sample (compare SB-labeled lanes in Fig. 5A and 5B). Consistent with the IL-10-mediated p38 MAPK inhibition, the treatment of BMDMs with LPS plus IL-10 resulted in a shift to less phosphorylated TTP bands in SDS-PAGE if compared with cells treated with LPS alone or with LPS plus IL-6 (Fig. 5C). This shift to faster migrating TTP bands was more pronounced after 6h of treatment. To address the IL-10 effect on TTP binding to AREs, we used the murine macrophage cell line RAW 264.7 since we were not able to detect TTP-ARE complexes in RNA EMSA experiments if BMDMs were used. LPS-stimulated RAW 264.7 cells express at least 3- to 5-fold more TTP than BMDMs (data not shown). Similar to BMDMs, LPS plus IL-10 treatment resulted in a more pronounced appearance of the hypophosphorylated TTP if compared with treatment with LPS alone or LPS plus IL-6 (Fig. 5D). Consistently, LPS plus IL-10 treatment caused an 50–80% increase in the formation of TTP-ARE complexes in RNA EMSA experiments compared with LPS alone or LPS plus IL-6 treatments (Fig. 5E). These data show that IL-10 decreases the phosphorylation of TTP and enhances the in vitro binding of TTP to TNF- α ARE in a manner similar to the pharmacological inhibition of p38 MAPK. These findings are in agreement with an increased TTP activity under conditions of reduced p38 MAPK activation as is the case in IL-10-treated cells. Interestingly, despite the reduced p38 MAPK activity and hence increased proteasome-mediated TTP degradation in IL-10-treated cells, the TTP protein levels were not diminished compared with LPS plus IL-6-treated cells (Fig. 5, C and D). We explain this observation by the sustained Stat3 activation and, hence, a strong Stat3-driven transcription of the TTP gene in IL-10-treated cells (supplemental Fig. 3C).

To test whether p38 MAPK activity protects mRNA from TTP-mediated decay, we examined the stability of TNF- α and IL-1 α

FIGURE 6. Effects of p38 MAPK inhibition on TTP-dependent re

duction of mRNA for TNF- α and IL-1 α . *A* and *B*, WT and TTP^{-/-}BMDMs were treated with LPS for 2 h, followed by treatment with SB or solvent control. Actinomycin D was added simultaneously with SB. The decay rates of TNF- α (*A*) and IL-1 α (*B*) were monitored by qRT-PCR for the times indicated. Remnant TNF- α or IL-1 α mRNA in percentage of the amount at the time point 0 of actinomycin D treatment is depicted.

mRNAs in the presence of the p38 MAPK inhibitor SB in TTP^{-/-} and control WT BMDMs. Two hours after LPS stimulation, SB was added in combination with actinomycin D. p38 MAPK inhibition caused a 4-fold decrease of mRNA stability of TNF- α (TNF- α without SB: $t_{1/2}$ =31 min; TNF- α with SB: $t_{1/2}$ =8 min) and an 8- to 10-fold decrease in IL-1 α mRNA stability (IL-1 α without SB: $t_{1/2}$ >2 h; IL-1 α with SB: $t_{1/2}$ =14 min; Fig. 6). In TTP^{-/-} cells, the inhibition of p38 MAPK caused only a modest (2-fold) decrease in mRNA stability of TNF- α mRNA (TNF- α without SB: $t_{1/2}$ =80 min; TNF- α with SB: $t_{1/2}$ =37 min with SB) and no detectable decrease of IL-1 α mRNA stability (IL-1 α without SB: $t_{1/2}$ =>2 h; IL-1 α with SB: $t_{1/2}$ =>2 h). These data indicate that the augmentation of mRNA decay by inhibition of p38 MAPK is to a large part TTP dependent. The contribution of TTP to the effects of p38 MAPK inhibition depends on the nature of the target mRNA.

We conclude that the IL-10-mediated reduction of p38 MAPK activity increases TTP-dependent mRNA decay. The combined ef-

FIGURE 7. Model of IL-10-mediated anti-inflammatory effects. IL-10 activates the transcription factor Stat3 that drives the expression of at least three effector genes. The still unidentified repressors of transcription are depicted by question marks. The other effector is TTP that requires the activity of a third effector, the DUSP1 phosphatase, that reduces the activity of p38 MAPK, thereby increasing the TTP-destabilizing activity toward specific ARE-containing mRNAs. The activity of DUSP1 can be mimicked by, for example, the p38 MAPK inhibitor SB.

fect of IL-10 on p38 MAPK activity and TTP expression contributes to the anti-inflammatory properties of IL-10.

Discussion

This study provides evidence that the mRNA-destabilizing factor TTP plays an important role in anti-inflammatory effects of IL-10. BMDMs deficient in TTP show a strongly reduced antiinflammatory response to IL-10. Two cytokines, TNF- α and IL1 α , were here demonstrated to be inhibited by IL-10 in a TTP-dependent manner. IL-10 appears to regulate TTP function in two ways (Fig. 7). First, IL-10 increases TTP expression in LPS-treated BMDMs. This augmented expression depends on Stat3, the key immediate effector of IL-10 effects. Second, IL-10 reduces at later time points the activity of p38 MAPK in LPS-treated BMDMs, hereby releasing TTP from the p38 MAPK-mediated inhibition.

Since the increased expression of TTP is not sufficient to initiate an anti-inflammatory response (as demonstrated by IL-6-mediated up-regulation of TTP), we conclude that the TTP-dependent IL-10 effects can be best explained by the combination of higher TTP expression and reduction of p38 MAPK activity.

TTP is known for its mRNA-destabilizing activity most notably, but not exclusively, toward TNF- α mRNA via AREs in 3'UTR. Thus, the IL-10-mediated rise in TNF- α decay rate is consistent with the elevated TTP levels and activity. In addition to TNF- α , our data suggest that IL-1 α is also a TTP target. The 3'UTR of the murine IL-1 α (GenBank accession no. NM_010554; <http://www.ncbi.nlm.nih.gov/GenBank/>) contains three elements (UAUUUAUA, AUAUUUAU, and UAUUAUUUAU) with similar sequences as the nonameric canonical sequence (UUAUUUAUU) recognized by TTP (45, 46). IL-1 α has so far not been described as TTP target despite of several recently published global screens for novel TTP targets (36, 47). However, these searches revealed that in such global screens important targets might be missed (e.g., TNF- α in the study of Stoecklin et al. (36)). In addition, the finding that TTP regulates also mRNAs with no obvious AREs in 3'UTR adds another degree of complexity to searches for TTP targets (47). The role of TTP in IL-10 responses is also in agreement with a study reporting IL-10-mediated ARE-dependent destabilization of CXCL1 mRNA (16). Importantly, in that study, the IL-10-induced mRNA decay was not detectable before 2 h of LPS/IL-10 treatment. This time point correlates well with the appearance of TTP

expression (42) and with our data showing that IL-10-mediated decay of TNF- α mRNA is not apparent before 2h of LPS treatment.

TTP-deficient cells are known to produce 2- to 3-fold more TNF- α (both mRNA and cytokine) than WT cells (26, 48). At the same time, IL-10 mRNA was shown to be targeted by TTP for degradation (36) and we found that the TTP-deficient BMDMs produce more IL-10 cytokine (supplemental Fig. S1). Thus, TTP cells produce more of both the proinflammatory TNF- α and the anti-inflammatory IL-10. Yet, the TTP cells still respond to IL-10 treatment (by e.g., Stat3 activation) and LPS treatment (by e.g., p38 MAPK activation) similarly as the WT cells (Fig. 4). We conclude that despite the 2- to 3-fold higher production of pro- and anti-inflammatory cytokines the TTP-deficient cells display comparable immediate-early response to pro-(LPS) or anti-inflammatory (IL-10) stimuli as WT cells.

We were not able to detect any differences in the TTP expression or p38 MAPK activity, the two key factors influencing the TTP function, when we compared the two protocols for IL-10 treatment. Thus, the higher absolute contribution of TTP to IL-10 responses in the pretreatment protocol suggests that IL-10 induces a cofactor of TTP during the pretreatment period. TTP serves as an adaptor protein linking mRNA to the mRNA processing and degradation machinery located in stress granules and processing bodies (21, 22). Some of the components of these complexes may be up-regulated by IL-10 during the pretreatment phase to enhance TTP function. Alternatively, IL-10-activated Stat3 may increase transcription of micro-RNAs such as micro-R16 that was shown to assist TTP in degradation of ARE-containing mRNAs (49). The influence of the experimental protocol on the IL-10 effects may also partially explain the discrepancy between our study and the study of Kontoyiannis et al. (14) who found no evidence for a role of TTP in IL-10 responses in the simultaneous treatment protocol. Instead, they proposed a rapid (within 15 min of IL-10 treatment) inhibition of p38 MAPK as the main mechanism of IL-10 action. We did not detect any inhibition of p38 MAPK activity by IL-10 at early time points regardless of applied protocol for IL-10 treatment (supplemental Fig. S2, A and B). These data are in agreement with several other studies showing no effect of IL-10 on p38 MAPK activity at early time points (2, 12, 50, 51). In a kinetics analysis of p38 MAPK activity, IL-10 was found to

exhibit a modest inhibitory effect on p38 MAPK activity at later time points (after 3 h of LPS plus IL-10 treatment) (18). The IL-10-mediated inhibition of p38 MAPK correlated with the induction of the dual-specificity phosphatase DUSP1, a MAPK phosphatase (18). We observed a similar reduction in p38 MAPK phosphorylation in terms of both, the magnitude and kinetics, and found that DUSP1 was required for this effect. The inhibition of p38 MAPK was caused specifically by IL-10 but not by IL-6 and correlated with the ability of IL-10 (but not IL-6) to induce sustained Stat3 activation. Consistently, IL-10 but not IL-6 was reported to increase expression of DUSP1 in LPS-treated macrophages (18). DUSP1 function as a critical p38 MAPK-inactivating enzyme provides the most likely explanation for the susceptibility of DUSP1^{-/-} mice to LPS-mediated toxic shock (52, 53). We speculate that the inhibition of the proinflammatory p38 MAPK by IL-10 at the later stages of macrophage stimulation is a key factor in immune homeostasis since p38 MAPK influences inflammation-related transcription, RNA stability, translation, as well as secretion. To mimic the inhibition of p38 MAPK by IL-10 at the late phase of stimulation, we used the p38 MAPK inhibitor SB and examined the effect of p38 MAPK on the TTP-dependent decrease of target mRNA molecules. Interestingly, whereas in the case of TNF- α a different decay rate (i.e., different decay rate in TTP^{-/-} and TTP^{+/+} cells) was observed also without p38 MAPK inhibition, for IL-1 α mRNA the TTP-dependent decay was detectable only if p38 MAPK was inhibited (Fig. 5). A similar

requirement for p38 MAPK inhibition has been recently described also for the TTP target CXCL1 (KC) mRNA (54). These findings indicate that the p38 MAPK-mediated control of TTP activity has a differential impact on target mRNAs. Although the TTP-dependent decay of some mRNAs (e.g., TNF- α) proceeds in the presence of p38 MAPK activity, the degradation of other mRNAs (e.g., IL-1 α and CXCL1) is strongly dependent on the kinase inhibition. This mechanism may play an important role in the specificity of TTP-mediated RNA decay: depending on the activation status of p38 MAPK or other kinases implicated in regulation of TTP activity (e.g., ERK or MK2), TTP would discriminate between various targets. The critical role that p38 MAPK plays in TTP-mediated RNA decay also suggests that the time point that is taken to determine RNA stability has a decisive effect on the outcome of the assay. The activation/inactivation profile of p38 MAPK is likely to vary between different experimental settings (e.g., amount and quality of LPS, the use of primary or immortalized cells, the origin of primary cells such as bone marrow or peritoneum) so that this aspect may also contribute to the variability of published data. For example, we did not observe an IL-10-mediated increase in TNF- α mRNA decay in peritoneal-derived macrophages.

Suppression of inflammatory responses by IL-10 is one of the key features in immune homeostasis. Despite many years of research, the question of how a single cytokine can specifically inhibit various inflammatory reactions with such a high efficiency remains unresolved. Recent studies suggest that known as well as yet unknown IL-10 effectors interfere on different levels and by different mechanisms with the intracellular inflammatory networks. This multitasking system employed by IL-10 is likely to be essential for the efficiency and specificity of the anti-inflammatory properties of IL-10. For example, the efficient and dominant inhibition of *Tnf* gene transcription by IL-10 still requires the remaining TNF- α mRNA to be removed from the system, i.e., by TTP. Although the primary IL-10-elicited signaling events that involve the IL-10 receptor, Jak1 and Tyk2 kinases, as well as the transcription factor Stat3, are to a large part common to all cell types, the more complex effects downstream of Stat3 may be cell type dependent. Thus, the function and activity of the Stat3-induced IL-10 effectors may be regulated by the environment within the particular cell type, hereby helping to explain the still incoherent and sometimes contradictory studies of the anti-inflammatory effects of IL-10.

Classification: Immunology

Abstract

Inflammatory diseases can result from uncontrolled immune responses that are, at the level of gene expression, significantly restrained by mRNA decay. However, the circuits regulating inflammation at the level of global mRNA decay, and how the specificity and timing of the elimination of different mRNAs is achieved are not known. Here we describe a relay of regulatory steps that orchestrate the timely removal of a large proportion of unstable inflammation-induced mRNAs in macrophages. Initially, the inflammation-activated p38 MAP kinase (MAPK) inhibits the mRNA-destabilizing function of the RNA-binding protein tristetraprolin (TTP). In this phase, mRNAs of only few genes are targeted by TTP for degradation. In contrast, at a low p38 MAPK activity that prevails during the resolution phase of inflammation TTP destabilized one third of inflammation-induced unstable mRNAs as illustrated by a genome-wide microarray-based analysis of mRNA decay. TTP itself is eliminated by the complete drop of p38 MAPK activity at the end of the inflammatory response. These findings reveal a self-regulatory mechanism that maintains the immune homeostasis by a temporally and qualitatively controlled mRNA decay.

Introduction

Inflammation is a rather stereotypical process that can be in most situations described by recruitment of innate immune cells to the site of inflammation and establishment of an inflammatory gene expression profile. A systematic comparison of reported high throughput gene expression studies revealed that the inflammatory expression profiles acquired upon stimulation of Toll-like receptors (TLRs) by pathogens or pathogens-derived products contain one large cluster of genes induced regardless of the TLR involved and the cell type used [152]. This common expression pattern represents a general inflammatory response signature. Several smaller clusters that are induced in addition to the common cluster are restricted to particular cell types and/or TLRs [152]. Sterile inflammation that is caused by e.g. tissue injury results from the release of inflammatory mediators, such as TNF and IL-1. These mediators establish a gene expression pattern that resembles the TLR-elicited general inflammatory response signature [2]. The inflammatory genes can be categorized by the kinetics of their induction into three groups [2]. The rate of mRNA decay was shown to play a critical role in the fast appearance and disappearance of the early inflammatory genes that also contain the highest number of AU-rich elements (AREs) in their 3' untranslated regions (UTRs)[2]. This is in agreement with the prominent role of AREs in the recruitment of mRNA-stabilizing or -destabilizing proteins [15, 20, 153, 154]. One of the best studied mRNA-destabilizing proteins is tristetraprolin (TTP). TTP, encoded by the *Zfp36* gene (TTP, as a more common name, is used synonymously for both gene and protein throughout) was initially characterized as a key inflammation-inducible *Tnf* mRNA-destabilizing factor whose deficiency resulted in multiple chronic inflammatory syndromes in mice [76]. After binding to AREs, preferentially but not exclusively to a UUAUUUAUU nonamer, TTP initiates the assembly of the mRNA degradation machinery thereby causing elimination of the bound mRNAs [21, 27, 155-157].

Because of their functions as sensors and effectors of inflammation, macrophages are often used to study inflammatory gene expression patterns. Macrophages stimulated with TLR

ligands exhibit highly dynamic gene expression profiles in terms of both the magnitude and timing. At the level of gene transcription, this dynamic behavior is brought about by a network of positive and negative feedback mechanisms [5, 158]. The transcription factors NF- κ B, C/EBP δ and ATF3 were shown to act as critical components of a regulatory circuit that determines the timing and duration of global expression changes. Another important broad range mechanism of controlling the inflammatory response employs mRNA stability [2]. The circuit regulating this key process is as yet unknown. The requirement for TTP in the IL-10-mediated inhibition of Tnf production [30] raised the question whether TTP is more generally involved in the removal of mRNAs encoding inflammation mediators, and if yes, how the specificity and timing of the elimination of different mRNAs is achieved. In this study we identify TTP as a non-redundant component of a negative regulatory loop that targets one third of intrinsically unstable inflammation-induced mRNAs for degradation. This negative feedback is driven by the dual function of p38 MAPK in the regulation of TTP activity. p38 MAPK is needed for TTP expression but it restrains the mRNA-destabilizing activity of TTP thereby preventing a premature degradation of many inflammatory mRNAs until the onset of the resolution phase of the inflammatory response.

Results

Genome-wide analysis of mRNA stability in LPS-stimulated WT and TTP^{-/-} macrophages.

To address the regulatory mechanisms that govern the specificity and timing of the removal of inflammation-induced mRNAs, we examined the global effect of TTP on mRNA decay rates in LPS-stimulated macrophages. In addition to its function as a critical *Tnf* mRNA-destabilizing protein, TTP was found to destabilize several other mRNAs encoding e.g. GM-CSF (Csf2), IL-3, IL-2, Ier3, IL-1 β , E47, IL-10, Cxcl1, Plk3 and IFN- γ in various cell systems [24-28, 31, 83, 159-162]. These findings suggested that TTP might be a more general mRNA-destabilizing factor than previously anticipated. However, three different large scale

screens did not support a more fundamental involvement of TTP in mRNA decay since only a limited number of previously unknown TTP targets were identified [23, 24, 27]. Importantly, these screens were not successful in the identification of one or more of the few already known TTP targets such as *Tnf*, the best characterized TTP target. To address the global role of TTP in mRNA decay, we decided to measure mRNA decay rates in LPS-treated bone marrow-derived macrophages (BMDMs) isolated from WT and TTP^{-/-} mice. To increase the sensitivity of the mRNA decay profiling we pharmacologically inhibited the LPS-activated p38 MAPK (using SB203580, a specific p38 MAPK inhibitor [163]) at the time of transcriptional blockage by actinomycin D (act D). Although p38 MAPK is required for TTP expression and TTP protein stability, it simultaneously blocks the mRNA-destabilizing activity of TTP [72]. We therefore inhibited p38 MAPK that the differences in mRNA decay between WT and TTP^{-/-} BMDMs would become more apparent. The pharmacological inhibition of p38 MAPK mimics an intrinsic inhibitory pathway that is driven by IL-10. IL-10 that starts to be produced by BMDMs after ~2-3 h of LPS treatment induces the expression of the phosphatase *Dusp1* that inactivates p38 MAPK [64]. The pharmacological inhibition of p38 MAPK has been successfully used by us and others to reveal an otherwise only poorly detectable TTP-mediated decay of several mRNAs ([28, 30, 164]). We employed this approach in a microarray-based analysis of mRNA decay. After 3 h of stimulation with LPS, BMDMs from WT and TTP^{-/-} animals were treated with act D and SB203580, and the remnant mRNA levels were measured at 45 and 90 min thereafter. TTP protein was induced after 3 h of LPS treatment (Fig. S1A), and remained detectable at 90 min after the transcriptional block despite of a considerable degradation caused by the inhibition of p38 MAPK (Fig. S1B). After normalization, filtering, and statistical analysis of the microarray data, the probe set IDs of the remaining genes (9847 from total 28853 present on the chip) were classified according to two criteria: 1) mRNA decay significantly ($P < 0.05$) increased above the overall average of the dataset in WT cells, and 2) additionally, a significantly ($P < 0.05$) slower decay in TTP^{-/-} compared to WT cells. Using these criteria mRNAs with P values below the 0.05 limit were selected (Table S1). In addition to P values, we also show the approximate half-lives of the

mRNAs (Tables 1 and S1). Nevertheless, it should be noted that the only criterion for classification of an mRNA as unstable or TTP-destabilized was the P value, but not the half-life. In addition, we analyzed the 3' UTRs for the occurrence and frequency of the sequence AUUUA, which represents the most basic ARE [15]. For the 3' UTR analysis, we took sequences downstream of the stop codon using the coding sequence (CDS) annotation from the GenBank (<http://www.ncbi.nlm.nih.gov/GenBank/>). Among the 9847 genes 1090 (10%) were found to be significantly unstable (Fig. S2 and Table S1), with the 25 most significantly unstable genes listed in the Table 1A. Out of these 1090 unstable mRNAs 309 (28%) displayed significantly decreased decay rates in TTP^{-/-} cells (Fig. S2). The mRNAs that were destabilized by TTP contained most of the so far known TTP targets (Tables 1B and S1). The reported and well characterized targets that were not found in our screen are known to be expressed in other cell types than BMDMs, i.e. in T cells (*Il2*, *Ifng*), B cells (*E47*) or mast cells (*Il3*). Consistently, the expression of these genes was below the threshold (see Methods) in BMDMs. Several of the known TTP targets did not rank among the top 25 unstable mRNAs though they all displayed TTP-dependent decays with P values < 0.05 (Table 1B).

Out of 309 TTP-destabilized mRNAs 116 transcripts (38%) had no AREs in their 3' UTRs (Fig. S2) confirming also other reports on ARE-free TTP targets [23, 24, 27]. In the analysis we defined the AREs as AUUUA pentamers present in the 3' UTR. By such a low-stringency definition of an ARE, we aimed at finding an estimate for the number of mRNAs that are degraded in a fully ARE-independent way. This type of analysis revealed that an unexpectedly high percentage (55%) of ARE-free mRNAs could be classified as unstable.

Analysis of TTP-mediated decay of *Cxcl2*, *Il6*, and *Il1a* mRNAs.

The increased mRNA stability in TTP^{-/-} BMDMs could be also explained by an indirect involvement of TTP, e.g. by an mRNA-stabilizing protein that may be more abundant in TTP^{-/-} cells. Thus, several criteria beyond the TTP-dependent decay must be met for an mRNA to be classified as a TTP target [24, 27]. We selected the mRNAs of *Il1a*, *Il6*, and *Cxcl2*

(GenBank IDs: NM_010554, NM_031168 and NM_009140, respectively) to examine the direct role of TTP in their decay. The P values for TTP-mediated decays and the half-lives of these mRNAs ranged from being strongly (*Cxcl2*) to modestly (*Il1a* and *Il6*) dependent on TTP (Table 1B). The 3' UTRs of all three mRNAs contained several AUUUA pentamers and at least one UAUUUUAU heptamer (Fig. S3A), the core TTP binding site [24]. Only in *Cxcl2* the ideal TTP binding nonamers UUAUUUAUU were found. Accordingly, all three mRNAs were able to bind to TTP in BMDMs as shown by RNA immunoprecipitations (Fig. 1A). To prove that TTP conferred instability through the 3' UTRs, and to exclude secondary effects of the general transcriptional block by act D (by e.g. inhibition of transcription of genes encoding labile RNases), we fused the 3' UTRs of the chosen mRNAs to a tetracycline-regulated beta-globin reporter [25]. Hela Tet-Off cells were co-transfected with a TTP expression construct and the 3' UTR reporters. After transcriptional stop by tetracycline, TTP accelerated the decay of all three targets but not that of the control reporter (3' UTR of *Hprt*) (Fig. 1B). To address the ability of TTP to bind to the AREs of the selected targets, the conserved AREs in the 3' UTRs of the chosen mRNAs were determined by alignment of several mammalian 3' UTRs (Fig. S3B). *Cxcl2* contained two and *Il1a* and *Il6* contained one TTP binding UAUUUUAU heptamers. RNA oligonucleotides comprising the conserved murine AREs were analyzed for their ability to compete with the optimal ARE of *Tnf* [21, 156] for TTP binding in RNA EMSA experiments (Fig. 1C). These experiments revealed that all three selected AREs successfully competed the *Tnf* ARE for binding to TTP. Finally, we validated the microarray data by measuring the decay rates of *Il1a*, *Il6* and *Cxcl2* in WT and TTP^{-/-} BMDMs using qRT-PCR. These experiments confirmed that all three mRNAs were degraded in a TTP-dependent way (Fig. 1D). Importantly, the TTP-mediated decay was detectable only if the cells were treated with the p38 MAPK inhibitor SB203580 at the time of the transcription inhibition. Without p38 MAPK inhibition, all mRNAs were stable during the time of measurement. Cumulatively, our data that were collected in several independent assays for the first time demonstrate that *Cxcl2*, *Il6* and *Il1a* are TTP targets in BMDMs.

mRNA decay in the LPS-induced transcriptome.

LPS-induced transcripts displaying the most dynamic expression profile, i.e. those showing a rapid and transient induction were recently shown to be particularly robustly regulated at the level of mRNA stability [2]. To examine the role of TTP in the stability of these mRNAs we used our recently published dataset of the LPS-induced transcriptome [165]. Transcripts which were induced at least 3-fold after stimulation with LPS for 3 h were investigated for stability using our mRNA decay dataset. Out of 548 LPS-induced transcripts 138 transcripts (25%) were classified as significantly unstable. Thus, unstable transcripts were enriched in the LPS-induced transcriptome compared to the whole transcriptome (25% compared to 10%) (Fig. 2 and Fig. S2). Out of 138 unstable LPS-induced transcripts, 116 (84%) contained AUUUA type AREs demonstrating that they were overrepresented in the LPS-induced fraction compared to the whole transcriptome (45%). Transcripts displaying TTP-dependent decay represented 33% of the unstable LPS-induced mRNAs (Fig. 2, Tables 2 and S2). Importantly, all immunologically relevant and known TTP targets (i.e. *Tnf*, *Il10*, *Cxcl1*, *Il1b*) as well as those identified in this study (*Il1a*, *Il6* and *Cxcl2*) were among the mRNAs destabilized by TTP. Several other important inflammatory mediators including *Ccl2*, *Ccl3*, *Ccl4*, and *Il23* were also found among the TTP-destabilized transcripts (Table 2). The results indicate that 1/3 of unstable mRNAs induced during the acute phase of the innate immune response is removed by TTP-dependent degradation, and hence they are putative TTP targets.

Although the LPS-induced transcriptome was enriched in unstable and ARE-containing mRNAs, many (64%) of the ARE-containing transcripts were stable. The broad definition that we used for an ARE (i.e. AUUUA) could not solely account for this finding since the 3' UTRs of e.g. *Cxcl3* (NM_203320) or *Ccl12* (NM_011331) (Fig. 2) contained UAUUUUAU heptamers that constitute functional AREs [24].

Several unstable mRNAs (e.g. *Dusp1* and *Dusp2*) containing putative core TTP-binding sites of the UAUUUUAU type were not degraded in a TTP-dependent way (Fig. 2 and Fig. S4). On the other hand, three unstable mRNAs (*Bcl3*, *Nfil3*, *Phldb1*) displaying destabilization by TTP

were lacking even the simple ARE, i.e. the AUUUA sequence in the 3' UTR (Fig. 2). These data confirm that although AREs have a prominent role in the mRNA decay in general, and in the TTP-dependent decay in particular, the presence of an ARE is neither sufficient nor necessary for an mRNA to be destabilized by TTP.

Timing and specificity of mRNA decay in the LPS-induced transcriptome is controlled by a negative feedback loop.

The analysis of the LPS-induced transcriptome revealed a so far underestimated extent of TTP-mediated removal of inflammatory mRNAs. In fact, *Socs3* mRNA has been reported in one study not to be an exclusive TTP target [166]. That study showed that co-transfected (overexpressed) TTP destabilized *Socs3* mRNA, yet the *Socs3* mRNA was not stabilized in TTP^{-/-} BMDMs and fibroblasts compared to WT cells. In contrast, our work revealed a non-redundant role of TTP in *Socs3* mRNA destabilization (Fig. 2 and Table 2), which we explain to result from the pharmacological p38 MAPK inhibition. Normally, this inactivation occurs gradually due to the endogenous IL-10 production that is needed for a sustained expression of *Dusp1* in LPS-treated BMDMs [30, 64, 66]. Consequently, the TTP-dependent mRNA decay should become more pronounced during the resolution phase of inflammation when the p38 MAPK-mediated inhibition of TTP activity is already strongly diminished. To substantiate this hypothesis examined the expression profile of TTP and activation kinetics of p38 MAPK during the stimulation of BMDMs with LPS (Fig. 3A). TTP was induced after 3 h of LPS treatment and remained high until 8 h. Thereafter, TTP gradually disappeared and after 25 h the TTP levels were comparable to those in unstimulated cells. Consistently, p38 MAPK activity was high until 6 h, thus supporting TTP expression (Fig. 3A). After 6 h p38 MAPK was declining thereby initiating the phase of TTP disappearance. The comparison of TTP expression and p38 MAPK activity suggested that after about 6 – 8 h the TTP activity should become more apparent since the protein was still present yet the inhibitory effect of p38 MAPK activity on the mRNA-destabilizing function of TTP gradually diminished. We tested this model by assaying the decay of *Cxcl2* mRNA at later time points after LPS

stimulation. At the 3 h time point only the use of the p38 MAPK inhibitor revealed an increased decay in WT compared to TTP^{-/-} cells (Fig. 1D). However, after 6 h and 8 h of LPS treatment *Cxcl2* mRNA was more unstable in WT compared to TTP^{-/-} cells even without the inhibition of p38 MAPK (Fig. 3). Importantly, the half-life of *Cxcl2* mRNA in WT cells decreased with time of LPS treatment (at 6 h $t_{1/2}$ was 75 min; at 8 h $t_{1/2}$ was 36 min) which is in agreement with the concomitant decrease in mRNA stability and p38 MAPK activity in the later phase of inflammation. These results confirmed that the pharmacological inhibition of p38 MAPK merely synchronized intrinsic regulatory events. Importantly, all stable LPS-induced mRNAs recently reported and analyzed in more detail by Hao and Baltimore [2] were found stable also in our study (*Mmp13*, *Ccl5*, and *Saa3*, Table S2) indicating that the pharmacological p38 MAPK inhibition did not introduce an artificial TTP-mediated mRNA degradation.

We conclude that the microarray-based mRNA decay dataset resulting from TTP⁻ and p38 MAPK-controlled negative feedback mechanistically explains the reported profound role of mRNA stability in the establishment of inflammatory gene expression profiles [2].

Discussion

Cessation of transcription does not immediately result in the termination of expression unless the already generated mRNAs are degraded. This has been demonstrated by studies describing lethal consequences of uncontrolled *Tnf* expression caused by the removal of AREs from its 3' UTR [167, 168]. On the other hand, immune cells must be able to robustly stimulate the expression of inflammatory genes in the early phase of the inflammatory response. Thus, a mechanism must be in place that actuates the inflammatory mRNA degradation with some delay after the initial inflammatory stimulus has been sensed. This study describes a negative feedback system that executes a delayed yet robust elimination of a large number of inflammation-induced mRNAs. The downstream effector of the system is the mRNA-destabilizing protein TTP whose expression is strongly up-regulated during the

initial phase of inflammation yet its mRNA-destabilizing function is in this phase blocked by a high p38 MAPK activity.

The differential mRNA decay profiling uncovered a previously unanticipated large number of TTP-destabilized mRNAs. For the following reasons we believe that the majority of mRNAs stabilized in TTP^{-/-} cells are direct TTP targets: 1) consistent with the prominent binding of TTP to ARE sequences, ARE-containing mRNAs were enriched in the TTP-dependent group (Fig. 2), 2) the most stringent criterion namely a slower decay in TTP^{-/-} compared to WT cells was used to identify putative TTP targets, and 3) three selected mRNAs were confirmed by detailed studies as TTP targets. Consistently, most of the best-characterized TTP targets were found in our profile. The large number of TTP targets results from the increased sensitivity due to the inhibition of p38 MAPK. This inhibition does not introduce an artificial TTP-dependent decay since no inhibition of the kinase is needed for detection of differential decay of *Cxcl2* mRNA in WT and TTP^{-/-} cells at 6 h or 8 h of LPS treatment, when p38 MAPK activity is already diminished by endogenous processes (Fig. 3). In addition, all stable LPS-induced mRNAs analyzed in more detail recently (*Mmp13*, *Ccl5* and *Saa3* [2]) were found stable also in our study (Table S2).

Our study indicates that the TTP-mediated mRNA destabilization process discriminates between the different targets depending on the p38 MAPK activity. This allows for a fine-tuning of the control of the inflammatory response in both kinetics and strength. Whereas some targets can be degraded at a high p38 MAPK activity (e.g. *Tnf*), for the decay of other targets a low p38 MAPK activity i.e. a high TTP activity is needed. This is illustrated by the high stability of the herein described three novel TTP targets, *Il1a*, *Il6* and *Cxcl2* (Fig. 1), after 3 h of LPS treatment when only the pharmacological inhibition of p38 MAPK reveals these targets to be unstable. After 6 and 8 h of LPS treatment *Cxcl2* becomes spontaneously unstable and the inhibition of p38 MAPK is no longer needed to detect TTP-dependent decay (Fig. 3). How does p38 MAPK enable TTP to discriminate between different targets is an important topic for future studies. The sequence of ARE alone cannot account for the observed differences since both *Tnf* and *Cxcl2* possess comparable AREs

yet only *Tnf* is destabilized by TTP at a high p38 MAPK activity. Thus, so far unknown regulatory elements in the 3' UTRs or proteins controlling mRNA stability are likely to be involved. Our study confirms that AREs play a dominant though not exclusive role in the TTP binding.

It is becoming increasingly clear how several regulatory circuits control the activation and subsequent attenuation of inflammatory responses. In this study we propose how a so far not appreciated negative feedback loop controls the removal of inflammatory mRNAs, thereby contributing to the self-limiting principle of inflammation. This regulatory mechanism employs a small number of successive events (Figure 4): 1) p38 MAPK-mediated expression of TTP with a low mRNA-destabilizing activity, 2) inflammation-induced IL-10 production, 3) IL-10-induced reduction of p38 MAPK activity, and 4) increase in TTP activity due to gradual inactivation of p38 MAPK (Figure 3). This regulatory system is adjusted by the concurrent p38 MAPK activity such that only a subset of TTP targets is destabilized at a time ensuring that pro-inflammatory mRNAs (e.g. *Tnf*) and anti-inflammatory mRNAs (such as *Il10* [27]) are not simultaneously eliminated. Due to the less efficient *Il10* mRNA removal at high p38 MAPK activity [164], the *Il10* transcript is efficiently degraded only during the resolution phase of inflammation when the IL-10 function is no longer needed. Finally, the complete drop of p38 MAPK activity at the end of the resolution phase causes degradation of the TTP protein (Fig. 3A). The profound role of TTP in the removal of pro-inflammatory mRNAs followed by the elimination of the anti-inflammatory *Il10* mRNA and the concomitant disappearance of the TTP protein indicates TTP to be a key factor regulating the immune homeostasis.

Materials and Methods

Reagents. Rabbit antibody to TTP was used as described [30]. LPS from *Escherichia coli* 055:B5 was used at a concentration of 10 ng/ml, actinomycin D (act D) and SB203580 (all Sigma) were used at a concentration of 5 µg/ml and 4 µM, respectively.

Cell culture. Primary macrophages were grown in L cell-derived CSF-1 as described [39]. $TTP^{-/-}$ (*Zfp36^{-/-}*) mice [76] were on C57Bl/6 background. Mice, 8 to 12 weeks old at the time of bone marrow collection, were housed under specific pathogen-free conditions. Mouse experiments were carried out in compliance with national laws. HeLa Tet-Off cells (Clontech) were grown in DMEM supplemented with 10 % FCS.

Microarray analysis. BMDMs from WT and $TTP^{-/-}$ mice were treated with LPS for 3 h. Medium was then replaced by fresh medium containing act D and SB203580 for 0, 45 and 90 min before RNA extraction. BMDMs from three different mice were used for each time point, i.e. in total 18 independent biological samples were collected (9 for WT and 9 for $TTP^{-/-}$ cells). Total RNA was then used for genome-wide expression analysis using Affymetrix Mouse Gene ST 1.0 microarrays containing 28853 genes. Standard protocols for labeling and hybridization were used (supporting Materials and Methods). Biotinylated DNA was hybridized to Mouse Gene ST 1.0 GeneChips and scanned following Affymetrix protocols. For generation of probe set expression values, CEL files containing probe level data were normalized using the RMA algorithm implemented in the Affymetrix Expression Console. Microarray data have been deposited in Gene Expression Omnibus (GEO, <http://www.ncbi.nlm.nih.gov/geo/>) and will be publicly accessible after acceptance of the paper. Subsequently the data were log transformed, after subtraction of a constant of 1.41 to account for the background, to achieve approximate normality and standardized to zero mean and unit variance. A linear model with genotype (WT and $TTP^{-/-}$), treatment (0 min, 45 min, and 90 min), and their interaction as independent variables was fitted. Residual variances were adjusted using an empirical bayes method [169] to obtain approximately t-distributed differences in gene expression values. It turned out that the resulting distribution of log 2 transformed signal intensities was slightly bi-modal, with a sharp peak at low values. We interpreted this peak as resulting from spurious background fluorescence of unexpressed genes. We thus filtered out genes expressed at an absolute level of less than 11.3, which falls into the valley between the two peaks. In addition, much less genes could be classified as unstable at the 45 min decay time point than at 90 min so that only the

results for the 90 min time point are presented. The most extremely regulated genes were then selected according to the following criteria: i) genes where the decay of mRNAs after 90 min was outside the one-sided $\alpha = 0.05$ limit (=one *; or $P < 0.05$) (t-value > 1.86); ii) genes where additionally the decay of mRNAs in TTP^{-/-} compared to WT cells after 90 min was outside the one-sided $\alpha = 0.05$ limit.

The half-lives determined using the microarray dataset. First, the average difference between the time point 0 (= transcription blockage) and 90 min (end of the decay assay) in the three biological replicates was calculated for each mRNA. These average decay values were then used to calculate the half-lives. For half-lives higher than 600 min the value was set as “stable”.

Analysis of mRNA decay in the LPS-induced transcriptome . LPS-induced genes were retrieved from our recently published microarray dataset (GEO accession number GSE8621, [165]) obtained by stimulation of BMDMs for 3 h with LPS. Transcripts that were induced at least 3-fold in comparison with unstimulated cells were examined with regard to their decay rates using the mRNA decay dataset from this study.

3' UTR analysis. Sequence files were retrieved from the GenBank using the Refseq accession numbers. A Perl script was implemented that uses regular expressions to find the core ARE motifs (i.e. the AUUUA sequence) in the nucleotide sequences and to annotate these hits in the GenBank files. Annotation of ARE motifs also included the assignment to the location classes (5' UTR, CDS, 3' UTR, NA) based on the annotation available in the GenBank files. Only AREs located in the 3' UTRs were included in the final analysis.

Measurements of RNA stability. 5×10^6 HeLa Tet-Off cells were transfected by nucleofection with 4 μ g pCMV-TTP or 4 μ g pCMV-TTP together with 1 μ g pTetBBB/IL1 α , pTetBBB/IL6, pTetBBB/Cxcl2 or pTet/HPRT, respectively. 24 h later 200 ng/ml tetracycline was added to stop transcription from the pTetBBB plasmids. Total RNA was prepared and analyzed by qRT-PCR as described. To assay mRNA stability in BMDMs, 5×10^6 cells were treated with LPS for 3 h or 6 h. Medium was then removed and fresh medium containing act

D or act D and SB203580 was added for the times indicated before preparing total RNA. RNA was analyzed by qRT-PCR as described before or used for microarray hybridization.

Statistical analysis. For microarray data a linear model analysis with genotype (WT versus TTP^{-/-}), treatment (0 min, 45 min, 90 min), their interaction, and individual as independent variables was fitted. Residuals were plotted, visually inspected, and tested for normality. Design matrices were specified such that the coefficients for the relevant comparisons could be calculated, e.g., between the baseline and induced states and between genotypes. Only the significance levels are reported. For the qRT-PCR data, normalized copy numbers were log-transformed, and mean values and standard deviations (SDs) were calculated (for n as described in the figure legends).

Acknowledgements

We wish to thank Perry Blackshear for providing TTP^{-/-} mice, Paul Bohjanen for the beta-globin reporter vector, Amanda Jamieson, Birgit Strobl and Christoph Schüller for critical reading of the manuscript. Figure and table legends

Fig. 1. Detailed characterization of *Il1a*, *Il6* and *Cxcl2* mRNAs as TTP targets. (A) TTP interacts with *Il1a*, *Il6*, *Cxcl2* and *Tnf* but not *Hprt* mRNA. WT or TTP^{-/-} BMDMs were treated

with LPS for 4 h and then used for RNA immunoprecipitation using anti-TTP antibody (AB) or preimmune serum control (SC). Isolated RNA was reverse transcribed and analyzed by RT-PCR using primers for *I11a*, *I16*, *Cxcl2*, *Tnf* and *Hprt*. The data are representative of 3 independent experiments. (B) 3' UTRs of *I11a*, *I16* or *Cxcl2* confer TTP-dependent instability. HeLa Tet-Off cells were transfected with reporter plasmids containing tetracycline-regulated β -globin fused to 3' UTRs of *I11a* (pTetBBB/*I11a*), *I16* (pTetBBB/*I16*), *Cxcl2* (pTetBBB/*Cxcl2*) and the control *Hprt* (pTetBBB/*HPRT*) together with pCMV-TTP or empty pCMV vector. 24 h after transfection, tetracycline was added to stop the reporter gene transcription from the pTetBBB constructs and RNA was isolated at the times indicated. Remnant mRNA, as determined by qRT-PCR, is shown in % of the amount at the time point of transcription stop. The values at each time point represent the mean and SDs of independent experiments (n=3). (C) TTP binds to conserved AREs within the 3' UTR of *I11a*, *I16* and *Cxcl2*. Extracts of HeLa Tet-Off cells expressing Flag-TTP (-tetracycline) or without Flag-TTP expression (+tetracycline) were assayed by RNA-EMSA for binding to Cy5.5 labeled *Tnf* ARE in the presence of competing 1x, 10x or 100x excess of unlabeled *Tnf* ARE, a random RNA sequence, *I11a* ARE, *I16* ARE or *Cxcl2* ARE. The identity of TTP-containing complexes was confirmed by supershift (ssTTP) using Flag antibody. (D) WT (TTP^{+/+}) and TTP^{-/-} BMDMs were stimulated for 3 h with LPS followed by transcriptional blockage with act D in the presence or absence of the p38 MAPK inhibitor SB203580 (SB). Decay rates of *I11a*, *I16* and *Cxcl2* were monitored by qRT-PCR at the indicated time points. Remnant *I11a*, *I16* or *Cxcl2* mRNA in % of the amount at the time point of act D treatment is depicted. SDs are shown (n=3).

Fig. 2. Venn diagram showing the decay properties of the LPS-induced transcriptome.

Unstable mRNAs represent 25% of LPS-induced transcripts (138 out of 548). One third (45 out of 138) of unstable mRNAs are destabilized by TTP. Ninety five % (42 out of 45) of TTP-destabilized mRNAs contain AREs in their 3' UTR. Examples of mRNAs in each category

are displayed. The Venn diagram is a graphical representation of the dataset shown in the Table S2.

Fig. 3. *Cxcl2* mRNA is destabilized by TTP at later phase of LPS treatment when p38 MAPK is declining and TTP is still expressed. (A) BMDMs were treated for indicated times with LPS and the expression of TTP (upper panel) and p38 MAPK activity (lower panel) was examined by Western blotting using antibodies to TTP and phosphorylated p38 MAPK (pp38 MAPK). For loading control, the blots were reprobated with antibodies to total p38 MAPK. (B) BMDMs were stimulated with LPS for 6 h (upper panel) or 8 h (lower panel) followed by act D treatment. *Cxcl2* mRNA decay was monitored for 90 min after the addition of act D. Note, no p38 MAPK inhibitor was used in this experiment. Error bars display SDs (n=3).

Fig. 4. Scheme of the qualitative and temporal control of mRNA decay by negative feedback in inflammatory response. Inflammatory stimulus activates the stress-regulated p38 MAPK that in turn induces the expression of TTP. At this phase, TTP mRNA-destabilizing activity is kept low by high p38 MAPK resulting of the destabilization of only few mRNAs (e.g. *Tnf*). p38 MAPK is gradually inactivated by the intrinsic negative feedback loop that is predominantly initiated by the endogenous IL-10 production and up-regulation of DUSP1, the p38 MAPK phosphatase. TTP activity unfolds as p38 MAPK decreases resulting in the removal of additional mRNAs targeted by TTP (e.g. *Cxcl2*).

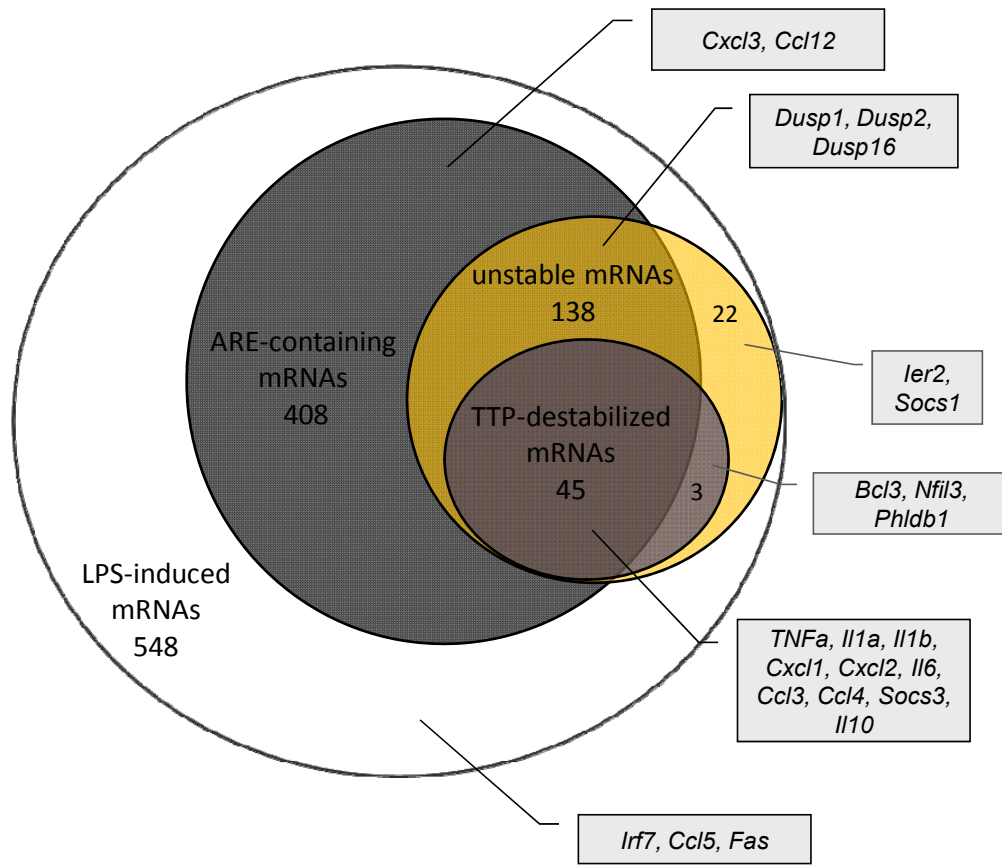

Table 1. Decay of most unstable transcripts is TTP-dependent. (A) Top 25 transcripts displaying most significant instability values. P values for stability in WT cells and for TTP-dependent decay are shown. Half-lives that were calculated on the basis of mRNA decay within 90 min after transcriptional stop serve for visualization of the P values. The number of AREs (of the AUUUA type) in the 3' UTR is depicted. Among these 25 mRNAs, 22 are degraded in a TTP-dependent decay (highlighted in gray), whereas only three transcripts

(*Clec2d*, *Hist1h1b* and *Cebpd*) are destabilized independently of TTP. (B) Reported TTP targets. Data as in (A) and references for reported targets are shown. (C) Three new TTP targets (i.e. *Cxcl2*, *Il1a* and *Il6*) characterized in this study.

Table 2. LPS-induced transcripts destabilized by TTP. Forty five LPS-induced unstable transcripts are shown that display TTP-dependent decay as judged by P values < 0.05 for decay differences in WT and TTP^{-/-} cells (i.e. P value for TTP-dependent decay). The transcripts are ordered according to their P values for decay in WT cells. Calculated half-lives support the visualization of the P values. Number of AREs (of the AUUUA type) in the 3' UTR and fold-induction by LPS are depicted. Reported TTP targets are shown with references.

Supporting Information

Materials and Methods

Labeling and hybridization to microarrays. Standard protocols for labeling and hybridization were followed. In brief, 200 ng of total RNA were reverse transcribed introducing by random priming a T7-binding site into the cDNA for subsequent *in vitro* transcription. The resulting cRNA was subjected to a second round of random primed cDNA synthesis in the presence of dUTP, that allows fragmentation of the cDNA with uracil DNA glycosylase and apurinic/apyrimidinic endonuclease 1. Fragmented cDNA was biotinylated by incubation with Terminal Deoxynucleotidyltransferase (TdT), and 5.5 µg of biotinylated DNA were hybridized to Mouse Gene ST 1.0 GeneChips overnight, washed, stained and scanned following Affymetrix protocols.

RNA immunoprecipitation. Isolation of TTP associated mRNAs under native conditions was performed essentially as described previously [170] with modifications. Briefly, the precleared extract of 1×10^7 TTP^{-/-} or WT primary macrophages was immunoprecipitated using TTP antiserum or preimmune serum control for 1 h at 4°C. Immune complexes were precipitated using protein A sepharose beads (GE Healthcare) coated with tRNA and RNase free bovine serum albumin (Ambion) by rotating for 1 h at 4°C. After 3 washing steps with lysis buffer, bound complexes were eluted using TES buffer (10 mmol/l Tris pH 8.0, 0.5 mmol/l EDTA, 0.5% SDS) at 65°C for 15 min. RNA was isolated and reverse transcribed as mentioned before. Samples were analyzed by RT-PCR performing 35 cycles using the primers as described for qRT-PCR.

RNA electrophoretic mobility shift assay (RNA-EMSA). To prepare TTP-containing extracts, HeLa-Tet-Off cells were transfected with pTRE-TTPfl plasmid as described [30]. 24 h after transfection the cells were washed with cold PBS and lysed in buffer containing 10 mM Tris-HCl (pH 7.5), 50 mM NaCl, 30 mM NaPP_i, 50 mM NaF, 2 mM EDTA, 1 % Triton X-100 and protease inhibitor cocktail (Roche). Extracts were cleared by centrifugation at 15.000 rpm. 5 µl cell extract (15 µg protein) were incubated with 0.5 µl Poly-U RNA (100

ng/μl)(Microsynth), 0.5 μl Cy5.5 5'-labeled Tnf ARE (1 pmol/μl), 1 μl RiboLock RNase Inhibitor (Fermentas) and 2.5 μl 5x gel shift buffer (200 mM KCl, 5 mM MgCl₂, 0.5 mM EGTA, 2.5 mM DTT, 100 mM Hepes-KOH pH 7.9, Glycerin 50% (v/v)) for 20 min at room temperature. For supershift assays, 0.5 μl anti-Flag M2 antibody (Sigma) was added. For competition experiments, 0.5 μl competing RNA oligonucleotides were added at a concentration of 0, 1, 10 or 100 pmol/μl for further 20 min. Samples were then separated on a 6 % polyacrylamide gel. The Cy5.5 signal was detected and quantified using the infrared imaging system Odyssey (LI-COR Biosciences). RNA oligonucleotides and the *Tnf* RNA Cy5.5 5'-labeled oligonucleotide were purchased from Microsynth. The RNA sequence was as follows: for Cy5.5 5'-labeled or unlabeled *Tnf* ARE, Cy5-TNFα-ARE 5'-AUUAUUUAUUUUUUUUUUUUUUUUUAUUUAUUUA-3'; as random sequence, random 5'-AGCUUAGGAAUAUCAUGUUUAAGUAG-3'; for the *Il1a* ARE, *Il1a*-ARE 5'-UAUUUAUAAAUAUAUUUAUGAUAAUUAUUAUUUUUAU-3'; for the *IL6* ARE, IL6-ARE 5'-UAUUUUUAAUUUAUUGAUAAUUUAAAUA-3'; for the *Cxcl2* ARE, *Cxcl2*-ARE 5'-UUAUUUAUUUAUCUAUGUAUUUUUUUUUUUUUU-3'.

Plasmids. pTetBBB/*IL1α*, pTetBBB/*IL6*, pTetBBB/*Cxcl2* and pTetBBB/*HPRT* were created by insertion of the full-length 3' UTRs of *Il1a*, *Il6*, *Cxcl2* and *Hprt* into the *Bgl*III and *Bam*HI site located in the β-globin 3'UTR of pTetBBB plasmid also containing a TRE in the promoter. The 3' UTRs were PCR-cloned using the following primers (restriction sites and flanking nucleotides for efficient restriction digests are included):

for *Il1a*,

fwd 5'- TTTTTTGGATCCGCAGCCTTATTTTCGGGAGTCTA -3'

rev 5'- TTTTTTAGATCTGTTGATAGTTACATGACACTGTGG -3'

for *Il6*,

fwd 5'- TTTTTTGGATCCGCGTTATGCCTAAGCATATCAG -3'

rev 5'- TTTTTTAGATCTTTTGTGTTGAAGACAGTCTAAACAT -3'

for *Cxcl2*,

fwd 5'- TTTTTTGGATCCGAAAGGAGGAGCCTGGGCTG -3'

rev 5'- TTTTTTAGATCTCATGAATAAATAAATGTGTCCACTTC -3'

for *Hprt*,

fwd 5'- TTTTTTGGATCCTGAGCGCAAGTTGAATCTGCA -3'

rev 5'- TTTTTTAGATCTATTTAAAAGGAACTGTTGACAACG -3'.

For constitutive expression of TTP, murine TTP was expressed from the CMV promoter in the plasmid pCMV-TTP.

Quantitation of gene expression by quantitative RT-PCR (qRT-PCR). Total RNA was isolated using Trizol-Reagent (Invitrogen) and reverse transcribed by Mu-MLV reverse transcriptase (Fermentas). Amplification of DNA was monitored by SYBR Green (Molecular Probes) as described [171]. Following primers were used: for murine *Hprt*, the housekeeping gene used for normalization., HPRT-fwd 5'-GGATTTGAATCACGTTTGTGTCAT-3', and HPRT-rev 5'-ACACCTGCTAATTTTACTGGCAA-3'; for human *Hprt*, hHPRT-fwd 5'-TGTGTGCTCAAGGGGGGC-3' and hHPRT-rev 5'-CGTGGGGTCCTTTTCACC-3'; for rabbit β -globin, RbGI-fwd 5'-TCCTAAGGTGAAGGCTCATGGCAA-3' and RbGI-rev GTGGTATTTGTGAGCCAGGGCATT; for *IL6*, IL6-fwd 5'-ATGGATGCTACCAAACCTGGAT-3' and IL6-rev 5'-TGAAGGACTCTGGCTTTGTCT-3'; for *Il1a* and *Cxcl2* the primer sets QT00113253 and QT00113505 (Qiagen), respectively.

Figure S1 TTP protein levels in LPS-treated BMDMs and the effect of p38 MAPK inhibition on TTP stability.

(A) BMDMs were treated with LPS for the times indicated.

(B) BMDMs were treated for 3 h with LPS followed by treatment with act D with or without SB203580 for the depicted times. TTP protein levels were examined by Western blotting with antibody to TTP. The blots were reprobated with antibody to ERK to control for loading.

Figure S2 Venn diagram showing the global distribution of unstable transcripts. Within 9847 transcripts 1090 (10%) were found unstable. Out of the 1090 unstable transcripts 309 (28%) mRNAs displayed TTP-dependent decay. 475 (45%) unstable transcripts contained AREs, 582 (55%) unstable transcripts were ARE-free. Unstable mRNAs that were destabilized by TTP were enriched for ARE-containing 3' UTRs: 185 out of 309 (= 61%) unstable TTP-destabilized mRNAs contained at least one ARE, 116 (39%) mRNAs were ARE-free. The Venn diagram is a graphical representation of the dataset shown in the Table S1.

Table S1. Complete list of unstable mRNAs (total 1090) containing 309 (28%) mRNAs which display TTP-dependent decay. P values for stability in WT cells and for TTP-dependent decay are shown. The transcripts are ordered according to the P values for decay in WT cells. Transcripts significantly stabilized in TTP^{-/-} cells and therefore putative

TTP-targets are highlighted in grey boxes. Half-lives were calculated on the basis of mRNA decay within 90 min after transcriptional stop. Number of AREs (of the AUUUA type) in the 3' UTR is depicted.

Kratochvill et al., Table S2

Table S2. Decay properties of 548 LPS-induced transcripts

Nr.	mRNA accession nr.	Gene name	P value for decay in WT	P value for TTP-dependent decay	Half-life in WT	Half-life in TTP-/-	Number of AREs in 3'UTR	Fold-induction by LPS

Table S2. Decay properties of 548 LPS-induced transcripts. P values for stability in WT cells and for TTP-dependent decay are shown. The transcripts are ordered according to the P values for decay in WT cells. In total, 138 unstable transcripts (i.e. P value < 0.05 for decay in WT cells) were found. Transcripts significantly stabilized in TTP^{-/-} cells (45 in total) are highlighted in grey boxes. Calculated average half-lives, the number of AREs (of the AUUUA type) in the 3' UTR and fold-induction by LPS are depicted.

6.3 Additional Data to the Manuscript

In addition to the three new TTP-targets characterized in detail in the manuscript (i.e. *IL-1 α* , *IL-6* and *Cxcl2*), the putative mRNA target *Bcl3* was selected for further investigation. This transcript displayed increased stability in TTP^{-/-} cells in the microarray analysis but did not contain any form of ARE (see manuscript, Table S2).

On the other hand we also started to validate the microarray results for *Dusp1* mRNA, which appeared to be unstable in a TTP-independent way, although its mRNA contains several AREs.

6.3.1 Role of AREs in TTP-mediated turnover

In the current view, TTP determines the mRNA stability by direct or indirect binding to AREs [9, 33]. In agreement with this model, AREs were enriched among putative TTP targets identified in our global screen (see manuscript figure S2). However, almost 40 % of TTP-targets detected had no ARE (defined as AUUUA) confirming recent reports that transcripts devoid of any ARE can be regulated by TTP [23, 24, 27]. One example for such an mRNA is *Bcl3* (NM_033601). It was highly expressed after LPS treatment (Manuscript Supplementary Table 2) and appeared to be stabilized in TTP^{-/-} macrophages. Nevertheless, its 3' UTR does not contain even the simplest AUUUA ARE sequence (figure 7A). In preliminary experiments we could confirm by qRT-PCR the increase in mRNA stability in TTP^{-/-} cells. TTP-dependent mRNA decay could only be detected when p38 MAPK was blocked (figure 7B) as shown for the other three validated mRNA targets (i.e. *IL-1 α* , *IL-6* and *Cxcl2*, see manuscript figure 1D). We therefore propose that TTP regulates *Bcl3* mRNA decay in a p38 MAPK dependent fashion similar to other TTP-targets. TTP might indirectly affect this target as shown for *iNOS* [172], or directly interact with *Bcl3* by a yet unknown non-ARE binding-sequence or secondary structure. Indirect effects caused by the up-regulation of other factors in the TTP^{-/-} background or by the treatment applied (e.g. SB203580 and act D) have to be excluded by more detailed analysis.

B)

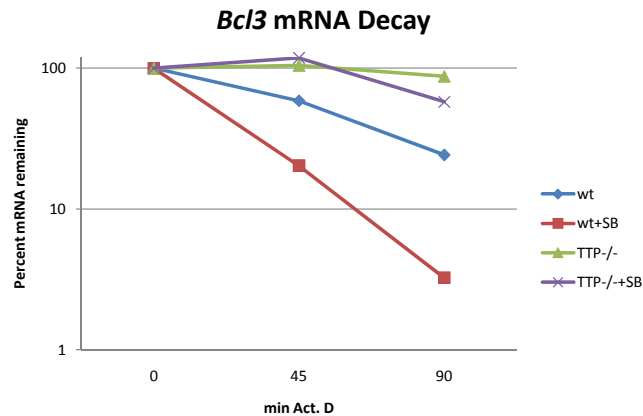

Figure 7: *Bcl3* mRNA, containing no ARE in the 3' UTR, is destabilized by TTP in a p38 MAPK-dependent way. **(A)** The murine 3' UTR of *Bcl3* lacks even the simplest core ARE sequence AUUUA. **(B)** WT and TTP^{-/-} BMDMs were stimulated for 3 h with LPS followed by transcriptional blockage with act D in the presence or absence of the p38 MAPK inhibitor SB203580 (SB). The decay rate of *Bcl3* was monitored by qRT-PCR at the indicated time points. Remnant *Bcl3* mRNA in % of the amount at the time point act D treatment is depicted.

Besides ARE-less TTP targets, our screen revealed a large amount of transcripts containing AREs that appeared to be stable (~ 85 % of all ARE containing transcripts). Therefore an ARE does not necessarily confer instability. Even among those messages that contain AREs and were unstable, not all of them were destabilized in a TTP-dependent manner (~ 60 % of ARE containing unstable messages). One of them, *Dusp1* mRNA, displays several ideal TTP binding sites (figure 8A). However, preliminary experiments measuring mRNA stability of *Dusp1* could again confirm the data acquired by the microarray analysis. This message

was very rapidly degraded independently of p38 MAPK activity or TTP (figure 8B). We therefore suggest that *Dusp1* stability is controlled by a TTP-independent mechanism that overrides any putative TTP-mediated mRNA degradation.

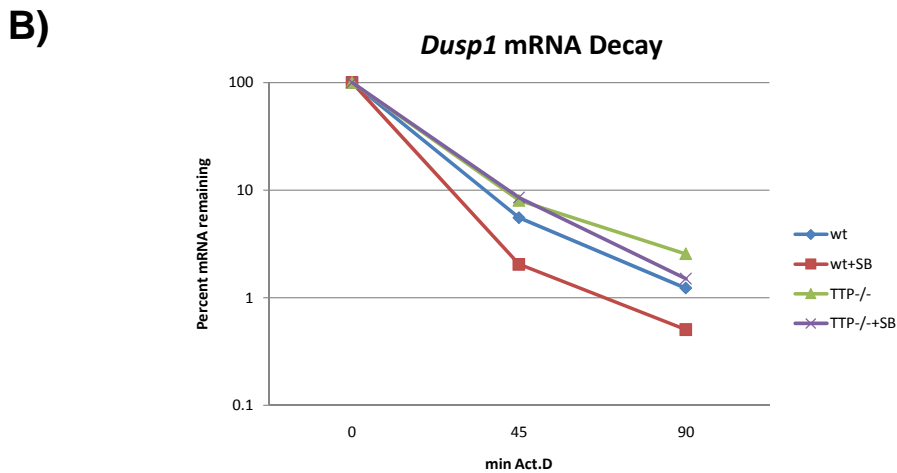

Figure 8: *Dusp1* mRNA, containing ideal TTP binding sites, is destabilized in a TTP-independent way. (A) The murine *Dusp1* has several AREs in its 3' UTR. The minimal ARE sequence AUUUA is highlighted in bold, UAUUUUAU sequences representing the core TTP binding site are underlined, ideal TTP binding consensus sequences UUUAUUUAUU are in boxes. (B) Wt and TTP-/- BMDMs were stimulated for 3 h with LPS followed by transcriptional blockage with act D in the presence or absence of the p38 MAPK inhibitor SB203580 (SB). The decay rate of *Dusp1* was monitored by qRT-PCR at the indicated time points. Remaining *Dusp1* mRNA in % of the amount at the time point act D treatment is depicted.

6.4 Conditional TTP Ablation

Due to the strong phenotype developed by the conventional TTP knockout mouse, it was so far impossible to study the role of TTP in different tissues and forms of diseases *in vivo* [76, 77]. We hence established a conditional TTP knockout mouse and tested its utility for the study of disease models.

6.4.1 Generation of conditional TTP knockout mice

The murine *zfp36* gene encodes two exons, a very small exon 1 (24 bp) and exon 2 (1710 bp). The targeting vector was designed to replace the second larger exon 2 of *zfp36*, which includes the two zinc finger domains (bases 314-401 and 428-515 of NM_011756.4) by a *LoxP* site flanked exon 2 next to a Neo cassette that is followed by a third *LoxP* site (figure 9 A and B). After electroporation of the targeting construct into 129/OlaHsd ES cells, clones were selected for Neo expression and were tested for correct integration by PCR of genomic DNA using the primer P1, P2 and P3 (figure 9A). To avoid potential adverse effects, the Neo cassette was removed by transiently transfecting a Cre recombinase-expressing construct and resulting clones were checked for correct excision by PCR using the primer P4 and P5 (figure 9C). The targeted allele was subsequently sequenced to avoid possible mutations within the *LoxP* sites during recombination for Neo excision (figure 9C). The resulting allele with exon 2 of *zfp36* flanked by *LoxP* sites is called TTP^{fl} hereafter (figure 9C).

Two ES cell clones were then injected into C57Bl/6 blastocysts to generate chimeric mice. These animals were further crossed with C57Bl/6 mice and heterozygote offspring were interbred or backcrossed into C57Bl/6 strain using speed congenics.

Homozygous TTP^{fl} mice (TTP^{fl/fl}) on a mixed background were then crossed to LysMCre mice (C57Bl/6) for myeloid specific TTP ablation [173].

Figure 9: **(A)** Schematic picture of the construct for conditional TTP deletion, **(B)** the genomic locus of TTP on chromosome 7 and **(C)** the TTP^{fl} allele after Neo cassette excision. The corresponding sites between the construct and the chromosomal locus are indicated by dashed lines. Exon 1 and exon 2 of TTP are depicted as E1 and E2 boxes. TK, thymidine kinase; Amp, ampicillin.

6.4.2 Role of TTP during acute inflammation

TTP^{fl/fl} LysMCre mice on a mixed background appeared normal at birth and did not show the decreased gain in weight typical for conventional TTP knockout (TTP^{-/-}) animals on mixed or C57Bl/6 background after a few weeks of age (data not shown). First we tested whether exon 2 of TTP^{fl} LysMCre mice is efficiently excised by doing PCR on chromosomal DNA. As shown in figure 10A, exon 2 was deleted in BMDMs from TTP^{fl/fl} LysMCre but not TTP^{fl/fl} and Wt animals. We then examined TTP protein expression in these cells by Western blotting. TTP is undetectable in macrophages without LPS stimulation. As depicted in figure 10B, after 3 and 6 hours of stimulation, TTP protein was induced in Wt as well as in TTP^{fl/fl}, but not in TTP^{fl/fl} LysMCre macrophages. Although the phosphorylation pattern with an increase of higher molecular weight TTP at later time-points was similar in TTP^{fl/fl} and Wt cells, TTP protein expression from the TTP^{fl} allele was slightly lower after 3 and 6 hours of LPS treatment than in Wt cells. We conclude that the established TTP^{fl} allele can be used to

specifically excise exon 2 of *zfp36* and therefore abrogate TTP expression by addition of a Cre recombinase.

Figure 10: TTP expression in BMDMs of myeloid-specific TTP knockout mice. **(A)** PCR analysis of chromosomal DNA from BMDMs of TTP^{fl/fl} LysMCre (fl/fl Cre), Wt and TTP^{fl/fl} (fl/fl) mice using the Primer P4 and P5 as depicted in (figure 9). The Wt allele results in an 1100 bp band, the slightly larger TTP^{fl/fl} allele in a 1200 bp and the excised exon 2 in a truncated 200 bp fragment. **(B)** BMDMs from Wt, TTP^{fl/fl} (fl/fl) or TTP^{fl/fl} LysMCre mice (fl/fl Cre) were treated with LPS for 3 or 6 hours or left untreated. TTP protein levels were examined by Western blotting with antibody to TTP. The blots were reprobated with antibody to p38 MAPK to control for loading. One out of 3 independent experiments is shown.

TTP was suggested to play a main role during chronic inflammation by regulating TNF α levels as demonstrated by studies using TTP^{-/-} mice. In these animals, predominantly macrophages are supposed to be the main source for elevated TNF α production responsible for the TTP^{-/-} phenotype [76]. However, without stimulation, TTP was almost undetectable in macrophages but could be transiently induced by various inflammatory stimuli like LPS (figure 10). We therefore hypothesized that TTP might also play a role during acute inflammation *in vivo*. The TTP^{-/-} mice are of poor health and the number and degree of

pathologies developed is rather heterogeneous [76]. The availability of the TTP^{fl/fl} LysMCre allowed us to use animals without an obvious health defect for *in vivo* studies. By using TTP^{fl/fl} LysMCre mice, we tested the role of myeloid TTP during endotoxic shock. Upon injection of a lethal dose of LPS, the engagement of the TLR4, the LPS receptor, predominantly on monocytes and macrophages induces the production of an array of pro-inflammatory cytokines [174]. We could show that the development of the subsequent lethal shock is enhanced when TTP is ablated in myeloid cells (figure 11). TTP^{fl/fl} LysMCre mice died significantly earlier than did their Wt and TTP^{fl/fl} littermates pointing out an important role for TTP in limiting the immune response elicited by myeloid cells during acute inflammation. This finding is in accordance with the role of TTP in macrophages, controlling mRNA stability of important pro-inflammatory cytokines as TNF α , IL-1 α , IL-1 β and IL-6 [31, 76] (see manuscript).

Figure 11: Myeloid-specific TTP knockout mice are more susceptible to LPS driven endotoxic shock. Kaplan-Meier blot of Wt mice (n=10; comprising Wt and TTP^{fl/fl} mice) and TTP^{fl/fl} LysMCre mice (n=12) treated with LPS by intraperitoneal injection. Significance of the difference of the obtained survival curves was calculated using Logrank Test (***: P<0.001).

6.5 Conditional TTP Overexpression

We next asked, as a “proof of principle”, whether an increase in TTP expression can be beneficial during different forms of inflammation. Therefore we aimed to establish a mouse-line conditionally overexpressing TTP. This system would allow the investigation of the tissue specific effect of increased TTP levels during infection, inflammation and other pathological conditions.

6.5.1 Generation of mice conditionally overexpressing TTP

The targeting construct (hereafter referred to as UbiC-flSTOPfl-TTP) for the generation of a transgenic TTP mouse-line was designed to integrate by homologous recombination into the collagen type A locus. The TTP transgene (cDNA) is expressed from the construct using a UbiC promoter known to drive ubiquitous expression in transgenic mice [150]. A floxed Neo and transcriptional STOP cassette in between the UbiC promoter and the *TTP* cDNA allows conditional activation of cDNA expression. The transcribed message is bicistronic facilitating the expression of an enhanced cyan fluorescent protein (ECFP) due to an IRES after the *TTP* cDNA (figure 12A). Transient cotransfections of the UbiC-flSTOPfl-TTP targeting construct and a Cre recombinase expressing plasmid into murine embryonic fibroblasts (MEFs) demonstrated the construct to be functionally expressing TTP in a Cre dependent way (figure 12B). ES cells were transfected with the targeting construct, selected for Neo expression and clones were tested for correct integration by PCR (figure 12C). Positive clones were further injected into C57Bl/6 blastocysts to generate chimeric mice. These animals were backcrossed into C57Bl/6 background using speed congenics. The mouse strain harbouring an UbiC-flSTOPfl-TTP allele will be hereafter referred to as TTP^{high}.

A) Targeting Construct

B)

C)

Figure 12. **(A)** Schematic picture of the construct for conditional TTP overexpression. **(B)** Anti-TTP immunofluorescence of MEFs transfected with the Ubi-flSTOPfl-TTP plasmid alone (-Cre) or cotransfected with a Cre recombinase expressing plasmid (+Cre). **(C)** PCR analysis of genomic DNA from Wt, homozygous TTP^{high} (h/h) and heterozygous (h/+) mice using the primer P6, P7 and P8.

TTP^{high} mice were then crossed to LysMCre mice, also on C57Bl/6 background. BMDMs of these animals were further examined for TTP overproduction. Untreated as well as LPS-treated (4 h) macrophages from TTP^{high} LysMCre mice did not produce significantly higher levels of TTP protein (figure 13A). In addition, analysis using a fluorescence-activated cell sorter (FACS) revealed a very limited expression of ECFP from the construct (figure 13B). Therefore a possible TTP overexpression might be too low to be detected by Western blotting of cells that produce high endogenous levels of TTP. Hence we tested whether these cells produce different amounts of TNF α after LPS stimulation. Decreased TNF α protein levels after LPS stimulation due to an increased *Tnf* mRNA degradation could indicate TTP overexpression in TTP^{high} LysMCre BMDMs. However, Wt and TTP^{high} LysMCre macrophages produced equal TNF α levels as depicted in figure 13C. We therefore conclude that TTP^{high} LysMCre BMDMs do not produce detectable higher amounts of TTP nor do BMDMs of these mice show the expected phenotype after LPS stimulation. A

possible explanation is that the UbiC promoter is too weak to drive robust TTP expression in this cell-type or that cells overexpressing TTP are lost due negative selection caused by possible harmful effects of constitutively increased TTP levels.

Figure 13. TTP^{high} LysMCre macrophages do not display elevated TTP protein levels. **(A)** BMDMs of Wt and heterozygous TTP^{high} LysMCre (h/+ Cre) mice were left untreated or were stimulated with LPS for four hours and TTP protein was measured by Western blotting. The blots were reprobed with antibody to panERK to control for loading. One representative example out of three is shown. **(B)** FACS analysis comparing ECFP expression of Wt and homozygous TTP^{high} (h/h) BMDMs (left panel), and Wt and homozygous TTP^{high} LysMCre (h/h Cre) BMDMs (right panel). One out of three independent experiments is depicted. **(C)** TNFα protein secreted by Wt and homozygous TTP^{high} LysMCre (h/h Cre) BMDMs after three hours LPS treatment was measured by ELISA. Data show mean ± SD of three independent experiments.

6.6 Role of TTP in Abelson-induced Transformation of B-cells

Pathologically stable mRNAs have been proposed to influence cancer development [122, 175-178]. In agreement with this, a recent study demonstrated that TTP can influence tumorigenesis in a mast cell tumor model. The authors could show that introduction of a TTP expressing plasmid into *v-H-ras* transformed PB-3c mast cells leads to decreased IL-3 expression and reduced tumor formation. Tumor formation of PB-3c cells transformed by *v-abl*, which happens in a nonautocrine manner independent of IL-3, was shown to be unaltered upon TTP transfection [83]. However, as TTP influences B-cell function, we investigated the role of TTP in a model of Abelson-induced B-cell lymphoma formation [161, 179]. B-cell progenitors can be easily transformed into tumor cell lines by single exposure to Abelson murine leukemia virus (Ab-MuLV) [180]. The *v-abl* oncogene provided by Ab-MuLV is a hybrid of the viral *gag* gene fused to a part of the *c-abl* gene encoding a nonreceptor tyrosine kinase [181].

We could show that TTP mRNA is readily expressed in spleen and bone marrow of Wt mice. In Abelson-transformed B-cell-lines however, TTP mRNA levels appeared to be diminished, indicating a putative negative selection for TTP expression (figure 14).

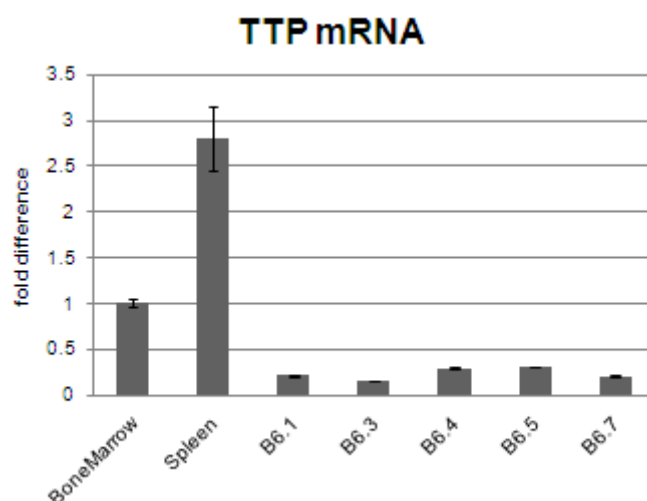

Figure 14. *TTP* mRNA expression in bone marrow, spleen and five Abelson-transformed B-cell lines (B6.1, B6.3, B6.4, B6.5 and B6.7). mRNA levels are normalized to *HPRT* and bone marrow *TTP* levels. Data show mean +/- SD of three experiments.

6.6.1 B-cell development in TTP knockout animals

Previous studies using mixed background TTP^{-/-} mice revealed some abnormalities of the hematopoietic system characterized by an increase in myeloid cells in peripheral blood, spleen and bone marrow and a slight decrease in B and T lymphocytes [76]. We could confirm for TTP^{-/-} mice on C57Bl/6 background an increased number of granulocytes and monocytes in blood and a small decrease for B-cells, especially late B-cell stages in spleen, lymph nodes and blood. However, there were no gross abnormalities detectable in the different B-cell progenitor stages indicating a minor role for TTP in normal B-cell development (see master thesis of Christian Machacek).

6.6.2 TTP in Abelson induced B-cell transformation

We first investigated the influence of TTP on the efficiency of Ab-MuLV-induced transformation of B-cell progenitors which includes the loss of growth factor requirement (i.e. IL-7). Bone marrow from Wt and TTP^{-/-} mice was infected with Ab-MuLV and then cultivated in cytokine-free methylcellulose. As illustrated in figure 15A, the number of clones from B-cell progenitors of TTP^{-/-} animals was increased compared to Wt. The colonies were identified by FACS as pre B-cells (CD19⁺/CD43⁺/B220⁺). As the number of CD43⁺/B220⁺ B-cell precursor cells is slightly different in Wt and TTP^{-/-} bone marrow as determined by FACS (43 % and 39 % pre B-cells of CD43⁺/B220⁺ Wt and TTP^{-/-} cells, respectively; see master thesis of Christian Machacek), we corrected the number of colonies per 10⁶ cells accordingly (figure 15B). We therefore propose that lack of TTP promotes Abelson-induced transformation of B-cell progenitors into cell-lines that grow independently of any growth factor as IL-7 (figure 15A and B). In *v-abl*-induced transformation of B-cells potentially one or more TTP target mRNAs are stabilized by the loss of TTP and alleviate transformation, being in accordance with a role of TTP as tumor suppressor [83].

Figure 15. **(A)** Bone marrow of Wt and TTP^{-/-} mice was infected with Abelson virus (vAbl) or left uninfected (Mock) and was subsequently grown in growth factor-free methylcellulose. One representative example is shown. **(B)** Colonies from two plates as seen in **(A)** from 3 independent experiments per genotype were counted. The resulting numbers were normalized to the amount of B-cell progenitors of WT and TTP^{-/-} bone marrow determined by FACS. Data show the mean value \pm SD. Statistical significance was determined using students t-test (**: $P < 0.01$)

6.6.3 Role of TTP in B-cell lymphoma formation

In addition to the transformation efficiency, the transformed clones were examined for tumor growth *in vivo* by subcutaneously injecting cells of four TTP^{-/-} and three Wt Abelson-transformed B-cell-lines into Wt mice (C57Bl/6). Each clone was thereby injected into four individual mice. After 10 days TTP^{-/-} clones showed increased average tumor mass, although the tumor size was very heterogeneous between different clones. We therefore conclude that lack of TTP leads on average to increased tumor growth. However, the heterogeneous growth rate of TTP^{-/-} tumors derived from different clones might indicate that additional unknown factors and/or secondary mutations work in concert with TTP. Whether the overall enhanced tumor formation is due to increased proliferation and/or reduced apoptosis has to be elucidated. As *VEGF* mRNA can be targeted by TTP [81], differences in vascularisation might also play a role. However, at the time of tumor-isolation, tumor-size

was too small to address this question. The precise molecular mechanism of the tumor-suppressive function of TTP in this tumor model will be investigated in future studies.

Figure 16. Mean tumor mass in Wt animals injected with 2×10^6 Wt or TTP^{-/-} Abelson transformed B-cells. Four independent TTP^{-/-} and three Wt clones were injected subcutaneously into four Wt mice each. Statistical significance was analyzed using nested anova (*: P<0.001)

7. FINAL DISCUSSION

7.1 Role of TTP-mediated mRNA Decay in LPS-treated Macrophages

After infection or tissue injury, the immune system must be able to induce a robust response. However, a prolonged or uncontrolled immune reaction can be as detrimental as a reduced one that might lead to inefficient pathogen clearing. In this context, mRNA degradation is of supreme importance because simply stopping transcription does not necessarily lead to the termination of expression unless the already generated mRNAs are removed [167]. This has been documented in a knockin mouse model bearing a stabilized version of *Tnf* mRNA (due to the deletion of AREs in the 3' UTR of *Tnf*). These animals developed chronic inflammatory arthritis and inflammatory bowel disease (IBD) pointing out the importance of mRNA stability in the regulation of gene expression and immune homeostasis [167]. Therefore a mechanism must be provided that can selectively stabilize or degrade certain transcripts during distinct phases of inflammation in order to allow both a strong induction as well as elimination of mRNAs in appropriate times and quantity. We could show that TTP, as a protein controlling mRNA removal, is part of a negative feedback loop that leads to the delayed degradation of a broad set of inflammation induced mRNAs. In this loop, pro-inflammatory stimuli like LPS trigger activation p38 MAPK. This kinase is important for the initiation of the immune response by up-regulating several mediators of inflammation. At the same time p38 MAPK increases expression of TTP as well as other anti-inflammatory proteins like IL-10. Consistently, p38 MAPK has been shown to play an essential role for both pro- and anti-inflammatory mechanisms [39, 61, 65]. In the initial phase of inflammation, high p38 MAPK activity blocks TTP function by phosphorylation and thereby protects certain mRNAs from TTP-mediated degradation as shown for *IL-1 α* , *IL-6* and *Cxcl2* (figure 17).

We demonstrated that only some very unstable messages like *Tnf* mRNA can be targeted by TTP for degradation after short LPS stimulation whereas most other TTP targets appear stable in this phase. Simultaneously, TTP expression is highly induced in BMDMs after p38

MAPK activation and TTP protein accumulates because a p38 MAPK-dependent phosphorylation of TTP blocks proteasome-dependent TTP-degradation [45]. After prolonged LPS treatment, the endogenously produced IL-10 gradually inactivates p38 MAPK. This inactivation happens via the IL-10 dependent up-regulation of the p38 MAPK phosphatase DUSP1 [30, 66] (figure 17). In addition, IL-10 signaling, by activating STAT3, further increases TTP expression in LPS treated macrophages [30, 64]. Activation of STAT3 by IL-6 signaling also increases TTP expression in LPS stimulated macrophages but does not lead to p38 MAPK inactivation. Hence, IL-6 does not initiate the TTP-dependent anti-inflammatory response seen for IL-10. Thus, our data indicate that both the IL-10-mediated increase of TTP expression as well as the IL-10-induced dephosphorylation of TTP are essential for the full anti-inflammatory function of this cytokine.

Figure 17. p38 MAPK regulates TTP functions in three ways. First, when p38 MAPK gets activated it increases TTP expression. Second, it rapidly blocks TTP activity by phosphorylation and third, it protects TTP-protein from degradation [39, 182]. IL-10 signaling at later stages additionally increases TTP expression and deactivates p38 MAPK thereby releasing the p38 MAPK imposed block on TTP activity [30].

In the ensuing work we showed that at later stages of inflammation, the reduced activity of p38 MAPK leads to diminished phosphorylation and thereby to increased activity of the accumulated TTP resulting to the TTP-dependent removal of a big proportion of inflammation induced unstable transcripts [72, 73]. By mimicking the gradually reduced p38 MAPK activity through the pharmacological inhibition of p38 MAPK we revealed that 30 % of all unstable LPS-induced mRNAs are degraded in a TTP-dependent way (see manuscript figure 2). TTP-target mRNAs like *Cxcl2* that appear stable in the initial phase of inflammation (e.g. 3 hours after LPS stimulation), become increasingly unstable at later stages, coinciding with an IL-10 dependent decrease in p38 MAPK activity. This finding is in agreement with the *Cxcl2* mRNA stability profile published recently, showing high stability after short LPS stimulation but reduced stability after prolonged LPS stimulation [2]. *IL-10* mRNA, which has been shown to be a TTP-target too, is also protected by high p38 MAPK activity from decay in the first stages after inflammation. This mechanism allows *IL-10* mRNA to accumulate until the IL-10 cytokine has initiated the resolution phase of the inflammation and the final decline of the p38 MAPK signaling [27]. Then IL-10 can be targeted for degradation by activated TTP in order to restore the original state.

Why targets as *Tnf* are degraded in a TTP-dependent way early during inflammation when p38 MAPK activity is high, whereas other messages like *Cxcl2* are stable in this initial phase is still obscure. A simple explanation might be the affinity of TTP to its target sequence. Suboptimal binding sites as the AREs of *IL-1 α* and *IL-6* may require higher TTP activity for efficient degradation. However, *Cxcl2* and *Tnf* contain both a similar ARE pattern. Therefore additional factors as other RNA-binding proteins or secondary structures controlling ARE accessibility might play a role. Although AREs in the 3' UTR have been demonstrated to be an important factor in TTP binding, it is still elusive how a TTP-target can be defined. For example, messages devoid of any form of ARE like *Bcl3* mRNA can be degraded in a TTP and p38 MAPK dependent way. Whether this decay happens through direct interaction of TTP with these messages or by more complex scenarios potentially involving other RNA-binding factors as shown for *iNOS* has to be determined [172]. On the other hand, some

mRNAs comprising AREs suggested to be optimal for binding were not targeted by TTP in our screen. These transcripts were either stable or were unstable even in the absence of TTP. Both situations could result from other factors known to stabilize or destabilize mRNAs. miRNAs for instance are a prominent candidate that might either co-operate with TTP or compensate for the lack of TTP. TTP possibly discriminates not only according to mRNA intrinsic factors as sequence and structural properties but also by competing or cooperating with other factors for binding.

7.2 The Role of TTP *In Vivo*

TTP is expressed in several tissues as liver, lung and colon [183-185] and is induced by various stimuli [36, 37, 39, 40]. However, the so far only described physiological TTP targets are *Tnf* and *GM-CSf*. Although TTP^{-/-} mice do not show elevated TNF α serum levels, administration of anti-mouse neutralizing antibodies to TNF α prevented the phenotype almost completely [10, 76]. However, anti-TNF α antibody treatment and the succeeding dominant neutralization of TNF α -signaling might obscure the influence of other factors involved. Accordingly, TTP^{-/-} mice deficient in both TNF α receptors, TNFR1 and TNFR2, did not develop arthritis or cachexia but still displayed after approximately six month of age medullary and extramedullary myeloid hyperplasia typical for TTP^{-/-} mice [186].

Our study could demonstrate that TTP controls an ample spectrum of mRNAs rather than only a small fraction. We therefore anticipate a broader function of TTP than the so far shown physiological role in controlling *Tnf* mRNA stability during different forms of chronic inflammation [76]. Although the conventional TTP knockout mouse has been published more than 10 years ago, only limited data have been obtained about the role of TTP in disease models because of the overall poor health, a heterogeneous phenotype and the short life span of these animals. Therefore many open questions remain unanswered. For instance, mice deleted for the ARE sequence within the *Tnf* 3' UTR as described before produce a stabilized *Tnf* message and higher amounts of TNF α protein. These animals spontaneously

develop IBD, an inflammation of the intestinal epithelium [167]. TTP is also expressed in this epithelium, yet TTP knockout mice do not develop any form of spontaneous IBD although *Tnf* mRNA is known to be stabilized in these animals [76, 82]. It is up to be determined whether TTP plays a minor role in controlling *Tnf* mRNA stability in the cells responsible for the development of TNF α -mediated IBD, or if other factors (e.g. IL-10) that are up-regulated in the TTP $^{-/-}$ mouse ameliorate the effect of higher TNF α expression. All these questions can be addressed only by employing animals that allow studies of TTP function *in vivo*, that is by using a homogenous cohort of mice conditionally deleting TTP. The mouse-line conditionally ablated for *zfp36* (the gene encoding TTP), that we have established, proved in preliminary experiments to be suitable for studies of the TTP function *in vivo*. These animals delete efficiently the floxed TTP allele in macrophages if crossed to LysMcre. Importantly, these macrophage-specific deleters do not show the typical TTP phenotype like reduced growth and body fat. This was unexpected, since these characteristic features of TTP-deficiency have been attributed to TNF α overproduction mainly by macrophages in a previous report [77]. In that study, transplantation of TTP $^{-/-}$ bone marrow into recombination activating gene-2 ($^{-/-}$) mice reproduced the TTP phenotype after a lag phase of a few months correlating with the slow repopulation by macrophages [77]. As TTP $^{fl/fl}$ LysMCre mice do not display this type of pathology, we suggest that other hematopoietic cells might influence the development of the phenotype. TTP-deficient macrophages may activate other effector-cells that also need to lack TTP expression in order to develop the phenotype seen in TTP $^{-/-}$ mice. However, a detailed analysis of the health status of myeloid-specific TTP knockout mice will be necessary in order to dissect the contribution of myeloid specific TTP expression.

Ex vivo experiments using TTP $^{-/-}$ macrophages from bone marrow, peritoneal cavity or fetal liver demonstrated that these cells produce more TNF α after LPS treatment than Wt cells [77]. In accordance with this finding, TTP $^{fl/fl}$ LysMCre mice are more susceptible to LPS-driven endotoxic shock. We therefore suggest a role for TTP during acute inflammation by controlling mRNA decay of a broad spectrum of transcripts, in particular by actuating the

expression of pro-inflammatory mediators as TNF α , IL-1 α , IL-1 β and IL-6 produced by myeloid cells [31, 76] (see manuscript). As myeloid-specific TTP knockout mice do not develop the full-blown phenotype seen in the conventional TTP knockouts, we hypothesize that TTP plays a more general role in immune homeostasis potentially involving other cells of the hematopoietic system.

9. ACKNOWLEDGEMENTS

First and foremost I want to thank Pavel for giving me the opportunity to do my PhD in your lab and for all your help, the numerous discussions as well as your guidance in becoming an independent scientist.

Thanks to Marina Karaghiosoff and Raimund Vielnascher for their assistance in generating the mouse lines, Prof. Veronika Sexl, Eva-Maria Putz and Nina Neugebauer for their help with the B-cell project and our other collaborators Prof. Roland Lang, Claus Vogl, Prof. Ivo Hofacker and Andreas Gruber. I am also grateful for the advice of Prof. Manuela Baccharini, Prof. Michael Jantsch and Prof. Mathias Müller as part of my PhD committee.

The work is of course dedicated to my parents, my sister and brother and to Nina who are and hopefully will be for a long time hence my most important support.

Special thanks to Roland for his friendship and for encouraging me in times of “unwanted” results. Thanks to all the former and current lab members for the nice time, especially Christian Machacek, who contributed a lot to this project.

Finally I want to acknowledge all my friends and people within the institute that made life as a PhD-student easier.

10. LEBENS LAUF

Daten:

Name Franz Kratochvill
Geburtsdatum 27.04.1982
Geburtsort Allentsteig, Austria

Wissenschaftlicher Werdegang:

seit Juli 2006 Doktoratsstudium an der Universität Wien mit dem Titel "The Role of Tristetraprolin in inflammation and disease" in der Gruppe von Prof. Pavel Kovarik

Mai 2005 – April 2006 Diplomarbeit mit dem Titel "Cell density-dependent regulatory systems controlling virulence of *Streptococcus pyogenes*" in der Gruppe von Dr. Emmanuelle Charpentier

Ausbildung:

Oktober 2001-2006 Studium der Molekularen Biologie an der Universität Wien

2000 Matura am Bundesrealgymnasium Waidhofen/Thaya

Konferenzen und Workshops:

Oktober 2009 RNA Club, Brno, Czech Republic

August 2009 "Eukaryotic mRNA Processing", Cold Spring Harbor, New York

September 2008 "Post-Transcriptional Control of Gene Expression: Mechanisms of mRNA Decay", FASEB Summer Research Conference, Lucca, Italy

August 2008 Workshop on Structure and Function of mRNP, University of Aarhus, Denmark

Präsentationen:

- Oktober 2009** Short Talk, RNA Club, Brno, Czech Republic
- September 2008** Short Talk, FASEB Summer Research Conference, Lucca, Italy

Tutorien:

- SS und WS 2009** Einführungsübungen in die Bioinformatik
- SS 2006** Einführungsübungen in die Biologie (Abschnitt Mikrobiologie und Genetik I)

Auslandsaufenthalte:

- August 2007 Labor von Prof. Carmo-Fonseca, Universidade de Lisboa, Lisbon, Portugal
- August 2004-Jänner 2005 Universidad Complutense de Madrid, Madrid, Spain (Erasmus)

Publikationen:

Schaljo B*, Kratochvill F*, Gratz N, Sadzak I, Sauer I, Hammer M, Vogl C, Strobl B, Müller M, Blackshear PJ, Poli V, Lang R, Murray PJ, Kovarik P., "Tristetraprolin is required for full anti-inflammatory response of murine macrophages to IL-10", J Immunol. 2009 Jul 15;183(2):1197-206.

11. CURRICULUM VITAE

Personal Data:

Name Franz Kratochvill
Date of birth 27.04.1982
Place of birth Allentsteig, Austria

Scientific Career:

since July 2006 Ph.D. student at the Max F. Perutz Laboratories at the University of Vienna with the title “The Role of Tristetraprolin in inflammation and disease” in the group of Prof. Pavel Kovarik

May 2005 – April 2006 Diploma thesis with the title “Cell density-dependent regulatory systems controlling virulence of *Streptococcus pyogenes*” in the group of Dr. Emmanuelle Charpentier

Education:

October 2001-2006 Study of molecular biology at the University of Vienna

2000 Grammar school graduated, completed with the formal exam “Matura”

Scientific Meetings and Workshops:

October 2009 RNA club, Brno, Czech Republic

August 2009 “Eukaryotic mRNA Processing”, Cold Spring Harbor, New York

September 2008 “Post-Transcriptional Control of Gene Expression: Mechanisms of mRNA Decay”, FASEB Summer Research Conference, Lucca, Italy

August 2008 Workshop on Structure and Function of mRNP, University of Aarhus, Denmark

Talks:

- October 2009** Short Talk, RNA Club, Brno, Czech Republic
- September 2008** Short Talk, FASEB Summer Research Conference, Lucca, Italy

Tutoring:

- Summer and winter term 2009** Introductory tutorial into bioinformatics
- Summer term 2006** Introductory tutorial into microbiology and genetics

Temporary Employment Abroad:

- August 2007 Lab of Prof. Carmo-Fonseca, Universidade de Lisboa, Lisbon, Portugal
- August 2004-January 2005 Universidad Complutense de Madrid, Madrid, Spain (Erasmus)

Publications:
