## **THE IMPACT ON THE BANKING SYSTEM FROM THE ACCESSION OF MACEDONIA IN THE EU**

### **Abstract**

The aim of this paper is to examine the impact on the banking system from the accession of Macedonia in the EU. EU enlargement is a complex process with enormous impact on the economy of the new member countries. The financial system of the new member country, and the banking system as a part of it, faces with the challenge of integration in the EU financial system. The best evidence of the EU accession impact on the banking system is the analysis of the basic characteristics of banking systems on the countries that became members in the last 20 years. The future banking development in new EU member countries will very likely follow some main patterns known from the old EU members. In a way banks from candidate countries can see their own future by observing the current developments in Western European banking. The process of restructuring in the banking system through consolidation which lead to increased concentration was one of the main drivers of changes. The existence of this process in new EU countries will be examined together with the structure of Macedonian banking system. It is

important to examine whether significant efficiency improvements were achieved in the banking systems of the new EU countries and are they result from the bigger market power or some other factor. Also, there were changes in the funding sources of the banks from the new EU countries with a lot of potentials for alternative funding possibilities. The financial crises made these potentials to evaporate, but on long term horizon, those opportunities will appear again. The low level of financial intermediation in new EU countries leaves space for increasing the range of financial services and their scope. Associated with the previous, a further enlarge of the market share on non-bank financial intermediaries in new EU members can be expected.

*Key words: European Union, banking sector, financial system, new member countries, funding, financial intermediation*

## **1. Introduction**

The process of enlargement of European Union (hereinafter: EU) is a complex one with strong impact on the economy of the country that will access. Stable financial markets are key to successful and sound economic development. Their development depends on a stable economic environment and vice versa, financial stability is, in turn, a precondition for sustained economic growth and an efficient monetary policy. Therefore the role of the financial markets in the process of convergence is of great importance. Only stable and sure financial sector can create stable framework conditions for economic growth.

One way of predicting the impact of EU accession to a banking system of a country is the idea that “possible forthcoming developments in the banking system are to a large extent determined by the developments in banking sectors of the “old” EU members” (Ribnikar and Kosak, 2006, p.2). In a way banks from countries candidates can predict their future transformation by observing the current developments in western European banking. This paper

will analyze the impact on the banking system from the accession in EU on the new EU countries according to the process of consolidation of the EU banking system, the level of concentration and the level of financial intermediation. Then based on the characteristics of the Macedonian banking system will be determined which of these effects could occur on Macedonian banks and will answer the question will the Macedonian accession to EU improve the efficiency of the banking system.

## **2. Concentration in the banking sector in EU**

The European banking system is in continuous process of consolidation. The consolidation in the banking industry starting from the 90-ties was a global phenomenon (Ribnikar and Kosak, 2006, p.2). The number of financial institutions was decreased through mergers and acquisitions. Prior to the establishment of the euro, both the suppliers and users of financial services undertaking cross border activities faced risks and costs associated with national currencies (Ekkayokkaya, Holmes and Paudyal, 2005, p 17). As such, competition in the bank M&A market was limited. The introduction of the euro saw the withdrawal of national currencies and, hence, the removal of this key element of risks and costs. Thus, with the introduction of the single currency, cross-border activity became more attractive and competition within national markets is expected to increase. The key efficiency that determents the M&A in the financial sector lies the achievement of economy of scales and the opportunity to cut costs by overlapping operations and consolidating back office operations. Despite the enlargement of the euro area through the accession of Greece (2001), Slovenia (2007), Cyprus and Malta (both 2008), Slovakia (2009) and Estonia (2011), the number of monetary financial institutions (MFIs,

2011) in the euro area has decreased by 20.2% or 1,991 institutions since 1 January 1999 (Figure 1). On 1 January 2011 Germany and France accounted for 40.8% of all euro area MFIs, a share similar to that recorded on 1 January 2010. On 1 January 2011 there were 9,921 MFIs resident in the EU, a net decrease of 271 units (-2.7%) since 1 January 2010. Compared with the situation on 1 January 1999 (10,909 MFIs in the EU), there has been a net decrease of 988 units (-9.1%), despite the addition of 1,608 MFIs on 1 May 2004, when ten new Member States acceded, and of a further 72 MFIs on 1 January 2007, when Bulgaria and Romania joined the EU.

**Figure 1**  
*Number of MFIs in EU / Euro area in the Period 1999-2011*

Source: European Central Bank. (2011), MFI statistics 2011, ECB, Frankfurt

What is important is that 78% of the total M&A are done by institutions from the same country (Campa and Hernando, 2005, p.9). Over the last decade there is no evidence of a significant cross border deals in the EU suggesting that banks have preferred to consolidate their market position within the national borders. Certainly, this tendency had its implications on the concentration in banking sector. From 1997 to 2003 the banking sector experienced a 23% reduction in the number of banks operating in the EU which led to moderate increase of the concentration on European level. In Spain the level of concentration (C5) increased from 32% to 44%, in France from 40% to 47%, in Germany from 17 to 22%, and in Italy from 25% to 27% (Campa and Hernando, 2005, p.12).

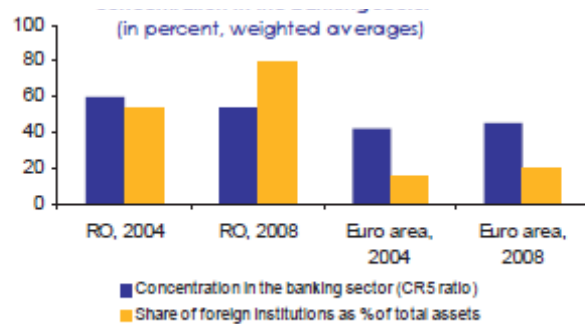

According to Charles Movit the concentration in “new” EU countries (countries that became members in 2004) before their accession in EU was higher than in the abovementioned EU countries. (CR5 in Czech, Bulgaria and Romania in 2004 was higher than 60%) Which is way their accession in EU didn’t have great impact on the concentration level. The other reason is that in the process of privatization European banks have

**Figure 2**

Concentration and Share of Foreign Institutions in the Banking Sector of Bulgaria, Romania and Czech Republic

Source: ECB, Structural indicators for the EU banking sector, January 2010.

Source: ECB, Structural indicators for the EU banking sector, January 2010.

Source: ECB, Structural indicators for the EU banking sector, January 2010.

already bought significant part of their banking systems. So with their accession they already had significant market share. The comparison between CR5 in 2004, when these countries become member states, and 2010 shows almost the same level of concentration. (Figure 2) The level of concentration can only be changed by the consolidation at the global and European level. Because dominant part of the banking sector is owned by foreign institutions, possible changes consolidation of the parent company can have influence of the concentration in these countries.

### **3. Level of financial intermediation in EU**

Financial intermediaries have important role in spurring growth (Bagehot 1873; Schumpeter 1912). The empirical studies show that “there is positive relationship between financial intermediation and growth”, which show that financial development is a good predictor of future growth” (King and Levine, 1993, p.20). These studies confirm the existence of a strong, positive contribution of the exogenous component of financial development to economic growth.

The level of financial intermediation can be measured with different indicators, and the proportion of total banking assets in GDP is considered the basic indicator. There is significant variation of this indicator in the 27 EU countries (Ribnikar and Kosak, 2006, p.3). Banking systems in the “old” EU countries with average total assets to GDP value of 272% clearly dominate new member states with 84%. According to Ribnikar and Kosak the explanation of these differences lies in the differences of the degree of economic development. Comparison between the degree of financial intermediation (total assets to GDP) and the degree of economic development (GDP per capita) of individual countries can confirm this relationship. On average countries with higher GDP per capita experience higher total assets to GDP ratios. So major movements can not be expected in the level of financial intermediation because GDP per capita

can't change over night, contrary these changes can happen only in medium or long term prospects (Figure 3)

**Figure 3**

*Total Banking Assets in % of GDP (vertical) vs. GDP per capita in EUR (horizontal) for Selected pool of EU member and Candidate Countries (2004 end of year data)*

Source: Ribnikar, I. and Kosak, M. (2006). Development prospects of the banking industry in the new EU member countries and forthcoming member countries, Faculty of economics, Rijeka.

The dependence between the level of development and financial intermediation can be confirmed if we analyze this ratio five years after the accession of the new EU countries in the union. As can be see from Figure 4 the level of financial intermediation is almost on the same level as from five years ago.

**Figure 4**

*Total Assets of Banks in EU member States in 2009, as a % of GDP*

Source: European Central Bank. (2010). Financial stability report. ECB, Frankfurt.

Also higher deposit correlation is associated with higher economic and financial development as measured by GDP per capita, the amount of electricity use, the availability of explicit deposit insurance and better credit environment (World Bank, 2011, p.3). There are smaller differences between the “old” and “new” EU member states in the share of non-bank deposits in GDP indicator compared to assets/GDP ratio (Figure 5). A pretty much straightforward explanation for the differences between the total assets/GDP indicator and non financial deposits/GDP indicator lies in the development characteristic of the modern financial systems. Market share of non banking sector is increasingly rising, and those alternative ways of saving are the main force for decrease the share of deposits in total liabilities in the banking sector. Accordingly banks will be forced to switch gradually from predominantly deposit based funding to different types of market based funding, which means that they will need to compete for funds in the market. Low level of deposits by nonbanks (as a percentage of GDP) in the countries candidates for EU accession is “attributable to the low income level and, subsequently, the population’s low disposition to save there are various factors that might explain the low ratio of loans to nonbanks to GDP” (Marianne Kager, 2002, p. 103):

- Bad loans. The yet unresolved problem of bad loans has inhibited loan expansion and/ or increased the risk aversion of banks.
- Legal and institutional factors. Inadequate collateral/mortgage provisions, insufficient law enforcement and/or slow enforcement of legal titles might also have played a role.
- Structural reasons on the demand side. Additional factors are foreign direct investment (FDI) and multinational enterprises direct financing.

**Figure 5**

#### 4. Efficiency of the EU banking system

In order to see will the accession in EU have impact on the efficiency of the banking system, using indicators, comparison will be made of the efficiency of the banking system before and after entering the EU. For the efficiency of the banking system after entrance in EU will be used data for 2001 and 2008 (Table 1 and Table 2) to abstract the impact of financial crisis.

**Table 1**

*Bank Profitability in Eastern Europe in 2001*

	Return on equity	Interest income	Loan loss provisions	Cost/Income ratio	Net income	Equity	Total assets per employee
	% of average total assets						EUR million
Poland	13.3	4.27	-1.09	63	1.11	8.2	0.653
Hungary	11.6	4.09	-0.58	66.1	1.04	9.4	1.194
Slovak Republic	6.6	3.74	0.66	107.7	0.56	7	1.814
Czech Republic	6.8	2.02	1.43	99.4	0.57	9.5	0.863
Slovenia	6.7	4.19	-1.27	55.3	0.68	9.9	1.413
18 Western European banks	18.6	1.6	0.2	69.5	0.7	3.9	8

Source: Marianne, K. (2002). *The Banking System in the Accession Countries on the Eve of EU Entry*, Bank Austria AG, Bank Austria AG, Vienna

According to Kager (Kager, 2002, p.107) a comparison of the balance sheets of the 25 largest banks in Eastern Europe and of 18 large Western European banks produces a similar picture: Eastern banks profits, expenses and net income are significantly higher than those of comparable Western banks. Eastern European banks lower return on equity (ROE) is chiefly attributable to the fact that their balance sheet equity is many times higher than that of Western banks, i.e. Eastern European banks are less leveraged. Banking sector productivity (as measured by assets per employee) was relatively low in the new EU countries, with Poland reporting the lowest result at EUR 0.65 million. On average, banking sector productivity in the new EU countries in 2001 was EUR 0.93 million (compared to an EU-wide average of EUR 8 million).

Table 2

*Bank Profitability in Eastern Europe in 2008*

	Return on equity	Interest income	Cost/Income ratio	Net income	Equity	Total assets per employee
	% of net assets	% of average total assets				EUR milion
Poland	22.94%	3.21%	60%	1.90%	7.77%	3.88
Hungary	19%	4.60%	42.60%	1.50%	7.68%	2.96
Slovak Republic	13.90%	4.50%	56.10%	0.90%	8.50%	2.95
Czech Republic	21.60%	4.70%	40%	1.16%	7.20%	2.6
Slovenia	16.28%	3.79%	52.72%	1.36%	8.60%	2.86
Macedonia	12.50%	8.10%	62.20%	1.40%	11.50%	0.67

Source: Central banks for sample countries

Five years after the accession to EU (Table 2), banking systems of the new EU countries have improved their efficiency. The return on assets has increased and as a result on the increased leverage the return on equity records multiplying. Banking operations are more efficient and the ratio of assets per employee increased for several times. Certainly, this is tightly connected with access to cheap sources of funds as a result of EU accession which increased the interest margin. Also the operational efficiency of analyzed banking sectors has increase and the cost to income ratio in some countries is two times smaller.

### **5. Structure of the banking system in the Republic of Macedonia**

The banking system in the Republic of Macedonia at the end of 2011 is comprised of seventeen banks and eight saving house (National Bank of The Republic of Macedonia, Report, 2011, p. 10) Thirteen of the total numbers of banks have foreign shareholders as dominant owners The banks with a dominant foreign ownership have above 87% share in the total capital of the Macedonian banking system and above 92% share in total assets (Figure 6). From the foreign owners, 78% are from EU member countries. This composition of the banking sector is stable after 2006 .

**Figure 6.**

*The Structure of the Balance Sheet Positions According the Banks' Ownership on 30.06.2011*

Source: National Bank of The Republic of Macedonia, (2011) Report on Banking System of the Republic of Macedonia in the second quarter of 2011, NBRM, Skopje

The analysis of the structure on the banking system by dominant shareholder points Greece and Slovenia as well as foreign portfolio-investors as owners with dominant share in the total assets of the banking system in the Republic of Macedonia. So EU countries are already dominant owners of Macedonian banking system (Figure 7).

**Figure 7.**

*Structure of Banks' Capital by Countries on 30.06.2011*

Source: National Bank of The Republic of Macedonia, (2011) Report on Banking System of the Republic of Macedonia in the second quarter of 2011, NBRM, Skopje

Although Greek banks owe more than 30% of Macedonian banking system, the obligatory limit is exposure to the parent Greek banks to be maximum 10% of the bank capital. Also Macedonian banks don't have investments in Greek securities and the deposits are invested in Macedonian companies and citizens (Bogov, 2011, p.1) which make Macedonian banks resilient from the developments in Greece.

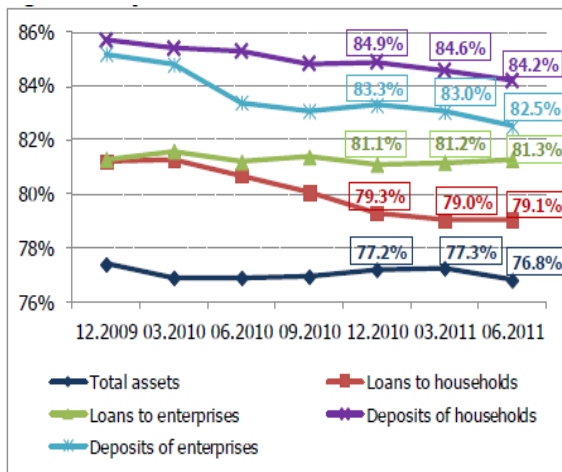

The structure of the Banks' assets and liabilities indicates that the Macedonian banks business model is traditional. The dominant banking activities are collecting deposits and granting loans. On the liabilities side at 31.12.2011 the deposits of non-financial entities with 70% are dominant source of financing (NBRM, 2012, p.23). The assets side is dominated by loans on non-financial entities whose share in the total assets is 55%. This kind of structure makes Macedonian banking sector resistant to direct influence of the world financial markets that was confirmed during the global financial crisis.

**Figure 8.**

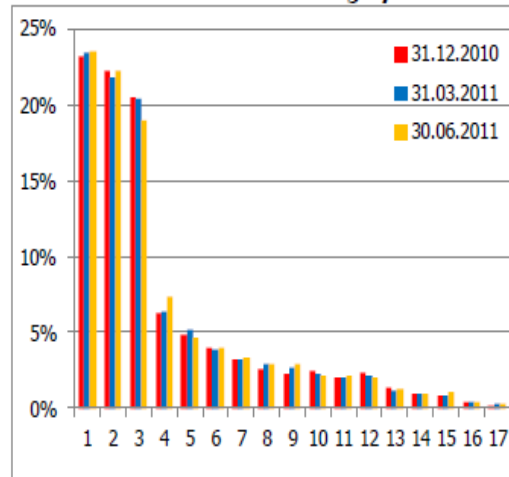

*Dynamics of the CR5 Ratio*

**Figure 9.**

*Market Share of Individual Banks in the Total Assets of the Banking System*

Source: NBRM, on the basis of data submitted by banks.

Source: NBRM, on the basis of data submitted by banks.

Concentration according to the CR5 ratio is high in all segments of banking activities, being highest in household deposits, and lowest in total assets. There aren't any big movements in the concentration level. The five largest banks on 30.06.2011 occupy over 75% of all segments of banks' operations. The market share of individual banks is stable. However, in thirteen out of seventeen banks the individual share in the total assets of the banking system is less than 5%, whereas in eleven of them it is below 3%. In contrast, only in three banks the individual share in the total assets of the banking system is greater than 19%.

The analysis of the capital adequacy ratio by individual bank (Figure 10) shows that big banks are constrained in their credit growth from their capital. The market distress leads to circumstances where it is difficult to ensure their recapitalization which leaves space for credit growth of the smaller banks.

### Figure 10

Capital adequacy ratio by individual bank

Source: National Bank of the Republic of Macedonia, (2012), Report on Banking System of the Republic of Macedonia for 2011, NBRM, Skopje

Considering the current concentration in the banking system, the EU accession, like in the other east European countries probable won't have impact on the structure of the banking system. With three main competitors that hold more than 65% of the market, the biggest three banks are market leaders and there isn't place for further increase of the concentration. This practically oligopoly structure has strong influence on the pricing of the banking activities. Considering the current structure of the banking system, a relatively high concentration and relatively large number of banks, there is need for consolidation of the banking system through acquisitions and /or mergers in the segment to other banks and thereby creating larger banks, which will increase the level of competition and contribute to reducing interest rates and spreads.

### 5.1 Level of financial intermediation in Macedonia

The banking system has dominant role in the financial system of Republic of Macedonia. This is way the impact from accession of the country in EU on the financial system will be most

felt in the banking system. With 90% share in the total assets of the whole financial system, banking system has dominant role in financial intermediation.

**Table 3**

*Structure of Total Assets of the Financial System of the Republic of Macedonia*

Structure of total assets of the financial system of the Republic of Macedonia						
	2005	2006	2007	2008	2009	2010
<b>Depository financial institutions</b>	<b>90%</b>	<b>90%</b>	<b>91%</b>	<b>90%</b>	<b>90%</b>	<b>90%</b>
Banks	88%	88%	90%	89%	88%	89%
Saving houses	2%	2%	1%	1%	2%	1%
<b>Nondepository financial institutions</b>	<b>10%</b>	<b>10%</b>	<b>9%</b>	<b>10%</b>	<b>10%</b>	<b>10%</b>

Source: National Bank of The Republic of Macedonia, (2011) Report on Banking System of the Republic of Macedonia in the second quarter of 2011, NBRM, Skopje

Until 2008, when the macedonian economy and the banking sector were influenced by the world financial crises, there was continual trend of strengthening the role on the banking sector as a financial intermediary. That trend continued in 2009 and 2010 but with smaller speed. The banking sector has crucial role in the financial system through channeling on the financial resources to the deficient economic agents.

Despite the positive movements, the financial intermediation in the Republic of Macedonia

Country	Assets/GDP	Loans/GDP
<b>Romania</b>	75%	43%

**Table 4**

*Level of financial intermediation in the banking system of R.M.*

<b>Bulgaria</b>	112%	78%
<b>Czech rep.</b>	117%	58%
<b>Slovenia</b>	153%	102%
<b>Estonia</b>	155%	114%
<b>Latvia</b>	161%	70%
<b>Cyprus</b>	822%	341%
<b>Malta</b>	721%	373%
<b>EU</b>	334%	141%
<b>R.Macedonia</b>	72%	44%

is still on the lowest level relative to some countries from the European Union, the EU average and the Eurozone average (Table 4) This is another confirmation that the level of financial intermediation is determined by the level of development. According to GDP per capita and the level of financial intermediation, on Figure 10 Macedonia is placed on the bottom. The accession in EU in medium term won't change the level of

financial intermediation, like it didn't had impact

on financial intermediation in "new" EU countries.

## 5.2. Efficiency of the Macedonian banking system

As can be seen in table 2, the efficiency of Macedonian banks is less than in new EU countries and far smaller than EU average. The return on equity is smaller than the EU average which is due on the small leverage and the high adequacy ratio. Also Macedonian banking sector although has a higher interest margin but the operating efficiency is poorer. The asset per employee ratio is on a 2000 level in Poland or Czech Republic and there is still room for enhancement of the operational efficiency through improvement of this ratio. The operational efficiency can be further improved which will result in decline of the cost to income ratio.

The banking system is mirror to the real economy and every recession is imperceptible in the financial world with certain time lag. Best evidence for the condition in the economy is the level of non performing loans. As can be seen from table 5, if we analyze the NPL to total loans ratio till 2008, accession to EU had influence on decreasing of this ratio. There are three main reasons: high credit growth, GDP growth and restructured banking system with EU owners. This trend further increased the efficiency of the banking system in “new” EU countries.

If we compare the NPL level in 2008, before the financial crises, Macedonian banking system has biggest NPL share from all selected countries. This implies that in that point Macedonian banking system was less efficient than the banking system of the “new” EU countries. Stated otherwise, from 1 euro loan the loss on the Macedonian banks was bigger. But, the financial crises also showed that although EU accession of the “new” EU countries had positive impact on the non performing portfolio, their banking system is more vulnerable to financial crises. The non performing ratio in almost all “new” EU countries is above the EU average. The conclusion that follows is that as a result of the new funding sources and GDP growth the accession to EU has effect on increasing the efficiency of the banking system.

**Table 5**

Source: World Bank data, <http://data.worldbank.org/indicator/FB.AST.NPER.ZS>.

As was mentioned earlier the financial intermediation in the Republic of Macedonia is still on the lowest level relative to EU members if we use Loans to GDP ratio. This also has effects on the efficiency of the whole financial system and the banking system as a part of it. If we use the Deposit/GDP as a indicator for financial intermediation Macedonian banking sector has better position than the comparison with Loans to GDP ratio. This is due to more developed other parts of the financial system apart for the banking system which creates possibilities for further development of the non banking financial activities in Macedonia.

## **Conclusion**

The banking system in Macedonia will face with new conditions, requirements and challenges of the EU-market. The competition from banking and non banking financial institutions is expected to increase. This will emphasize the need for innovations at the traditional banking products that banks offer now and creation of new banking products will gradually replace part of traditional products.

Regarding the process of consolidation that is present in EU, the level of concentration in Macedonian banking sector is high. With three main competitors that hold more than 65% of the market, the biggest three banks are market leaders and there isn't place for further increase of the concentration. However, consolidation can be expected at the small and medium banks in order to survive the domestic oligopoly structure and the new foreign competition.

Dramatic changes in the level of financial intermediation can not be expected. This variable depends from the level of economic development and the empirical examples show that the accession in EU didn't had impact on financial intermediation in "new" EU countries. Further improvement can be expected in the efficiency of the banking system. These two trends will

decrease the interest margin and interest rates. Finally, the accession in EU will require restructuring and reorganization of the economy as a whole, and the banks will be part from that process.
