A B S T R A C T

Dynamic Dielectric Spectroscopy and Thermo Stimulated Current were used to investigate of the dielectric relaxation of hybrid Poly(vinylidene-fluoride-trifluoroethylene)/barium titanate 700 nm composites with 0–3 connectivity. The results obtained by this method allow us to describe the physical structure of these composites in the glassy state at a nanometric scale. The decrease of the activation enthalpies and activation entropies involved in the dynamics of the α relaxation is attributed to: the decrease of Cooperative Rearranging Region sizes and an increase of intra/inter macromolecular interactions in the amorphous phase with the volume fraction.

Molecular mobility

1. Introduction

Since the discovery of the piezoelectric behavior of Poly(vinylidene fluoride) by Kawai [1] and the understanding of the molecular origin of this electroactivity [2–4], organic ferroelectric materials have attracted interest for their potential use in specific applications such as low weight and flexible sensors [5]. Many classes of polymers have shown piezoelectric and pyroelectric activities such as odd-polyamide [6], even odd polyamide copolymer [7] and more recently the copolymer Poly(vinylidene fluoride-trifluoroethylene) [8,9] and the terpolymer Poly(vinylidene fluoride-trifluoroethylene-chlorofluoroethylene) [10,11]. For electroactive applications, Poly(vinylidene fluoride-trifluoroethylene) copolymer was the most useful polymer because of the low poling field required to induce ferroelectric behavior and high dielectric permittivity compared to other class of ferroelectric polymer. Another important point was that this copolymer did not require any mechanical stretching before polarization [12]. Even if this polymer might have interesting ferroelectric properties, the piezoelectric and pyroelectric properties were much lower than well-known inorganic ferroelectric materials [13,14]. To overcome this disadvantage, some works were devoted to the dispersion of ferroelectric inorganic fillers (micron size) in a polymeric matrix in 0–3 connectivity [15–18]. Depending on the polarization procedure [19–22] these authors have shown that the ferroelectric inorganic nanoparticles could increase the ferroelectric activity of organic materials. As far as we know very few works were devoted to the influence of the ferroelectric inorganic phase on the molecular mobility of the organic phase. In this study, barium titanate submicron particles with a mean

diameter of 700 nm were dispersed in a Poly(vinylidene fluoride-trifluoroethylene) matrix. Dynamic Dielectric Spectroscopy and Thermo Stimulated Current were employed to characterize the physical structure in the solid state of these composites at a nanometric scale.

2. Experimental section

2.1. Samples elaboration

The mean diameter of barium titanate particles is 700 nm. Poly(vinylidene-fluoride-trifluoroethylene) (P(VDF-TrFE) 70:30 mol.%) has been purchased from Piezotech (France). Copolymer powders were dissolved in acetone. Then the required barium titanate powder (BaTiO₃ or BT) was dispersed to form a mixture by ultrasonication. During 24 h the samples were dried at 110 °C to remove the solvent. The composites were hot pressed to form thin films of thickness from 100 to 150 μ m. Volume fraction (ϕ) of ceramic in composite films ranged from 0.07 to 0.41.

2.2. Dielectric measurements

Dynamic Dielectric Spectroscopy (DDS) was performed using a BDS400 covering a frequency range of 10^{-2} Hz–3.10 [6] Hz with 10 points per order of magnitude. Experiments were carried out in a temperature range from -150 °C to 150 °C. Dielectric isothermal spectra were measured every 2 °C. Before each frequency scan, temperature was kept constant to ± 0.2 °C. The real ϵ' and imaginary ϵ'' parts of the relative complex permittivity ϵ^* were measured as a function of frequency f at a given temperature T .

The complex dielectric permittivity ε^* was fitted to the Havriliak–Negami (HN) function:

$$\varepsilon^*(\omega) = \varepsilon_\infty + \frac{(\varepsilon_s - \varepsilon_\infty)}{(1 + (i\omega\tau)^{\beta_{HN}})^{\gamma_{HN}}}$$

Where ε_s is the static permittivity, ε_∞ is the permittivity at high frequency, and β_{HN} , γ_{HN} are the Havriliak–Negami parameters.

Complex Thermo Stimulated Current (TSC) thermograms were carried out on a TSC/RMA Analyser. For complex experiments, the sample was polarized by an electrostatic field during $t_p = 2$ min over a temperature range from the polarization temperature $T_p = 50$ °C down to the freezing temperature T_0 . Then the field was turned off and the depolarization current was recorded at a constant heating rate ($q_h = +7$ °C.min⁻¹), the equivalent frequency of the TSC spectrum was $f_{eq} \sim 10^{-2}$ – 10^{-3} Hz. Elementary TSC thermograms were performed in a polarization window of 5 °C. Then the field was removed and the sample cooled at a temperature $T_{cc} = T_p - 30$ °C. The depolarization current was recorded at a constant heating rate ($q_h = +7$ °C.min⁻¹). Each elementary thermogram was recorded by shifting the polarization window 5 °C toward a higher temperature. The temperature dependence of relaxation times follows an Arrhenius–Eyring equation:

$$\tau(T) = \frac{h}{k_B \cdot T} \cdot \exp\left[-\frac{\Delta S}{R}\right] \cdot \exp\left[\frac{\Delta H}{RT}\right]$$

Where k_B is the Boltzmann's constant, R is the gas constant; h is the Planck's constant, ΔH the activation enthalpy and ΔS the activation entropy.

3. Results

3.1. Dielectric relaxation modes in dynamic spectroscopy

The evolution of ε'' versus frequency is shown in Fig. 1 for P(VDF-TrFE)/BaTiO₃ composites with 700 nm particle sizes. The volume fraction was maintained at 41%. Two dielectric modes were clearly identified in the amorphous phase: a lower temperature mode γ at -80 °C associated with the mobility of short sequences, an intermediate temperature mode α at -25 °C was attributed to the dielectric manifestation of the glass transition. At higher temperature, an isothermal phenomenon attributed to the dielectric manifestation of the Curie transition of the organic phase was observed. The Curie temperature [19] of these particles was already pointed out by Differential Scanning

Fig. 1. Imaginary part of the dielectric permittivity, isochronous between 100 Hz and 1 MHz for P(VDF-TrFE)-BaTiO₃ 700 nm with 41% vol.

Calorimetry (DSC) near 130 °C. Furthermore, relaxation times extracted from these data with Havriliak Negami equation did not show an influence of the BT particles on P (VDF-TrFE) mobility.

Fig. 2(a) showed the evolution of the conservative part of the dielectric permittivity at 26 °C as a function of frequency for various volume fractions. BT particles increase drastically the ε' value from 18.3 at 23% vol. to 136 at 61% vol. An evolution of ε' at low frequency was also observed for high BT content. Heterogeneous systems were generally characterized at low frequency and high temperature by an important increase of the dielectric permittivity associated with the Maxwell Wagner Sillars [23] (MWS) phenomenon. The values of ε' at 1 kHz as function of ϕ were reported in Fig. 2(b). Experimental values were well fitted by the following Bruggeman [24] model for volume fraction below 45% vol.

$$(1-\phi) \frac{\varepsilon_m - \varepsilon_{eff}}{\varepsilon_m + 2\varepsilon_{eff}} + \phi \frac{\varepsilon_{incl} - \varepsilon_{eff}}{\varepsilon_{incl} + 2\varepsilon_{eff}} = 0$$

With ϕ the volume fraction, ε_m the dielectric permittivity of the matrix, ε_{incl} the dielectric permittivity of the inclusion, ε_{eff} the effective dielectric permittivity.

According to this model, we could extract the dielectric permittivity of the inorganic part of the composite. From the Bruggeman model, ε' of

Fig. 2. (a) Real part of the dielectric permittivity as function of frequency for P(VDF-TrFE)/BaTiO₃ composites with ϕ ranging from 0% (■), 23% (●), 41% (▲) to 61% vol (▼). (b) Real part of the dielectric permittivity P(VDF-TrFE) (●) as function of volume fraction of BaTiO₃ 700 nm fitted by Bruggeman model in red line.

BaTiO₃ 700 nm was evaluated to be nearly 1500. This value was in good agreement with bulk ceramic sintered from BaTiO₃ 700 nm particles using Spark Plasma Sintering technique. For $\phi > 45\%$, the experimental points departed from the Bruggeman model. For these high volume fractions the connectivity of the biphasic system was modified by the agglomeration of particles. 0–3 connectivity, in Newnham notation, did not govern the physical properties of the composite. For $\phi > 45\%$, 3–3 connectivity described the dispersion of inorganic particles in the P(VDF-TrFE) matrix. This point was already observed in thermoplastic polymers by Scanning Electron Microscopy and published [25].

3.2. Dielectric relaxation modes in thermal analysis

The influence that the volume fraction of inorganic fillers has on the molecular mobility of the amorphous phase of the polymeric matrix was characterized using the thermally stimulated currents technique. The samples were polarized under an electric field of $E_p = 1$ kV/mm at $T_p = 50$ °C for 2 min then the composites were cooled at $T_{cc} = -100$ °C and short-circuited for 2 min. Thermograms were recorded from -90 °C to 110 °C.

Complex TSC thermograms at low temperatures of P (VDF-TrFE)/BaTiO₃ composites were presented in Fig. 3. The relaxation modes shown in this figure were related to the amorphous organic phase. For purpose of clarity and in order to compare composites depolarization current was normalized to: the fraction of polymer in the composite, the electric field and the surface of the sample. Whatever the volume fraction of BaTiO₃ particles, two modes were observed in the low temperature range. As the low temperature relaxations γ and α appeared below the poling temperature, these relaxations have been attributed to dipolar relaxation phenomena. In the inset, the complex dielectric manifestation of the Curie transition of P(VDF-TrFE) appeared at 100 and 110 °C, which is consistent with DDS and DSC measurements [26,27]. These high temperature relaxations are associated with the crystalline phase of the copolymer. Relaxation of the barium titanate particles was pointed out near 130 °C.

The localization versus temperature of the γ mode was influenced by the volume fraction of inorganic phase. In the case of P(VDF-TrFE) the γ mode appears at $T_\gamma = -80$ °C. This mode was attributed to the dipolar relaxation of small segments of the macromolecule in the amorphous phase. As the barium titanate fraction increased the

peak temperature increased. The peak temperature of the composite made with $\phi = 41\%$ was 10 °C higher than the copolymer.

The peak temperature of the α relaxation until 41% volume fraction was not so influenced by the volume fraction than γ mode. This relaxation was attributed to the glass transition dielectric manifestation. The peak temperature $T_\alpha = -20$ °C was in agreement with DDS measurement of the α relaxation for P(VDF-TrFE) copolymer.

The amplitude of the TSC thermograms increased with the volume fraction. As the barium titanate was a pyroelectric material, it was attributed to the pyroelectric current associated with the inorganic phase.

Fractional TSC [28] was employed to characterize the fine structure of the major α relaxation. For each elementary thermogram, the sample was polarized under a field $E_p = 1$ kV/mm in a temperature range of 5 °C. Fig. 4 shows the complex and the associated elementary thermograms of the α mode of P(VDF-TrFE) copolymer. From each elementary thermogram, we calculate the relaxation times associated with the α relaxation process. The evolution of α relaxation times had an Arrhenius behavior; we were able to determine the activation enthalpies and the activation entropies at various temperatures according to the barriers theory.

The activation enthalpies versus elementary peak temperatures of the α mode for P(VDF-TrFE) and composites with ϕ ranging from 7% to 41% were shown in Fig. 5. Whatever the volume fraction, the activation enthalpies of the composites reach a maximum value before decreasing. The null activation entropy was represented by a dashed line also called the Starkweather "line" [29]. For α mode, experimental data departed from the Starkweather "line" whatever the volume fraction. It meant that the molecular mobility of the dipolar entities involved in the α process generated an increase in entropy. This point was consistent with a relaxation process attributed to the glass transition molecular mobility. As the volume fraction of barium titanate filler increased the maximum and minimum values of the α relaxation enthalpy decreased: enthalpy values were closer to the Starkweather "line" and the α relaxation process tended to be more localized.

4. Discussion

The pre-exponential factor τ_0 which was proportional to the activation entropy (ΔS) was presented in Fig. 6 for the α mode of P(VDF-

Fig. 3. TSC thermograms ($T_p = 50$ °C $E_p = 1$ kV/mm, $T_{cc} = -100$ °C) of P(VDF-TrFE)/BaTiO₃ composites with ϕ ranging from 0% (■), 7% (●), 23% (▲) to 41% (▼). Each thermogram is normalized to the volume fraction of P(VDF-TrFE). (inset) The high temperature range of the TSC thermograms.

TrFE) and composite. In both cases a linear relationship between enthalpy and entropy was observed which is characteristic of a compensation law.

As the volume fraction of the barium titanate was increased, the pre-exponential factor was shifted toward higher times. τ_0 and the activation entropy were inversely proportional to the increase of inorganic content and were responsible for a decrease of the system disorder. It was attributed to an increase of intra/inter macromolecular interactions in the amorphous phase. The main variation reports in this study concerned the evolution of τ_0 with the enthalpy. It can be seen in Fig. 6 that the maximum and minimum values of the activation enthalpies decrease with an increase in volume fraction. This decrease is proportional to ϕ . The temperature range of these enthalpies was not influenced by the inorganic content. The decrease of the maximum and minimum values of the activation enthalpies was attributed to the decrease of the Cooperative Rearranging Regions (CRR) size [30,31] with the volume fraction.

Dynamic Dielectric Spectroscopy measurements showed that the physical structure was independent from the volume fraction in the liquid state. In the same way, Differential Scanning Calorimetry experiments, not presented here for purpose of clarity, showed that the barium titanate contents only had a weak influence on glass

Fig. 5. Activation enthalpy ΔH versus the maximum peak temperature T_{max} of each elementary TSC process of α mode for P(VDF-TrFE)/BaTiO₃ composites with ϕ ranging from 0% (■), 7% (●), 23% (▲) to 41% (▼). The Starkweather line is plotted in dotted line.

Fig. 6. Pre-exponential factor τ_0 (in inverse proportion with the activation entropy ΔS) versus the activation enthalpy ΔH for P(VDF-TrFE)/BaTiO₃ composites with $\phi = 0\%$ (■), 7% (●), 23% (▲), 41% (▼).

transition and crystallinity ratio of these composites. Thus, the decrease of the CRR size cannot be explained by any interactions between inorganic and organic phases. Densification effect due to the increase of the inorganic content and an increase of the intra/inter macromolecular interactions in the amorphous phase appeared to be responsible for the slight decrease of the CRR size. This conclusion was in good agreement with a recent study [25] made on PA11/BaTiO₃ composites.

5. Conclusion

The work presented here describes the influence that the volume fraction of inorganic barium titanate submicron fillers with a mean diameter of 700 nm has on the molecular mobility of the amorphous phase in the copolymer P(VDF-TrFE).

The TSC measurements were used to investigate the physical structure of the composite at a nanometric scale. The densification of the matrix with the increase of the inorganic phase causes a decrease of the activation enthalpies and activation entropies. These activation parameters were involved in the dynamics of the α relaxation associated with the delocalized mobility near T_g . These evolutions were attributed to the decrease of Cooperative Rearranging Region sizes and an increase of intra/inter macromolecular interactions in the amorphous phase.
