ABSTRACT

New results are presented concerning the topotactic self-assembly, n-type doping and band-gap engineering of an intrazeolite tungsten(VI) oxide supralattice $n(WO_3)$ -Na₆₆Y, where $0 < n \leq 32$, built-up of single size and shape $(WO_3)_2$ dimers. In particular it has been found that the oxygen content of these dimers can be quantitatively adjusted by means of a thermal vacuum induced reversible reductive-elimination oxidative-addition of dioxygen. This provides access to new $n(WO_{3,x})$ -Na₅₆Y materials (0 < x \leq 1.0) in which the oxygen content, structural properties and electronic architecture of the dimers are changed. In this way one can precisely control the oxidation state, degree of n-doping and band-filling of a tungsten(VI) oxide supralattice through an approach which can be considered akin to, but distinct in detail to, that found in the Magneli crystallographic shear phases of non-stoichiometric bulk WO3... Another discovery concerns the ability to alter local electrostatic fields experienced by the tungsten(VI) oxide moieties housed in the 13Å supercages of 16(WO₃)-M₅₆Y, by varying the ionic potential of the constituent supercage M⁺ cations across the alkali metal series. This method provides the first opportunity to fine-tune the band-gap of a tungsten(VI) oxide supralattice. A miniband electronic description is advanced as a qualitative first attempt to understand the origin of the above effects. The implications of these discoveries are that cluster size, composition and intrinsic electrostatic field effects can be used to "chemically manipulate" (engineer) the doping and band architecture of intrazeolite supralattices of possible interest in quantum electronics and nonlinear optics.

Introduction

The photo-oxidation of α -cage encapsulated $n\{W(CO)_6\}$ -Na₅₆Y, provides a mild, clean and quantitative synthetic pathway to single size and shape tungsten(VI) oxide clusters $n(WO_3)$ -Na₅₆Y according to the reaction [1]:

$$h\nu$$

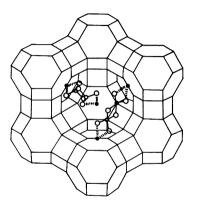

n{W(CO)₆}-Na₅₆Y + 9n/2O₂ -----> n(WO₃)-Na₅₆Y + 6nCO₂

A combination of spectroscopy, diffraction and microscopy probes, including EXAFS structure analysis [2] demonstrates that over the entire $W(CO)_6$ loading

range $0 < n \ll 32$, achieved via the sequential saturation impregnation-photooxidation process:

$$\begin{array}{rcl} 16\{W(CO)_6\}-Na_{56}Y & ---> & 16(WO_3)-Na_{56}Y \\ 8\{W(CO)_6\}, 16(WO_3)-Na_{56}Y & ---> & 24(WO_3)-Na_{56}Y \\ 4\{W(CO)_6\}, 24(WO_3)-Na_{56}Y & ---> & 28(WO_3)-Na_{56}Y \\ & & & & & \\ & & & & & \\ & & & & & \\ 1\{W(CO)_6\}, 30(WO_3)-Na_{56}Y & ---> & ---> & 32(WO_3)-Na_{56}Y \end{array}$$

only the population of the $(WO_3)_2$ dimer building block grows within the zeolite Y host lattice to form a $8(WO_3)_2$ -Na₅₆Y supralattice of dimers at half-loading n=16, and eventually to a $8\{(WO_3)_2\}_2$ -Na₅₆Y supralattice of dimers-of-dimers (rather than $(WO_3)_4$ tetramers) at saturation-filling n=32, as illustrated in Figure 1.

 Chem-X space filling model for two (WO₃)₂ dimers anchored to the 4Na⁺ site II cations in the *a*-cage of Na₅₆Y, (2c).

In this summary paper we report for the first time simple chemical means of injecting variable numbers of electrons into, and adjusting the magnitude of the electrostatic fields experienced by the tungsten(VI) oxide moieties in zeolite Y.

Results And Discussion

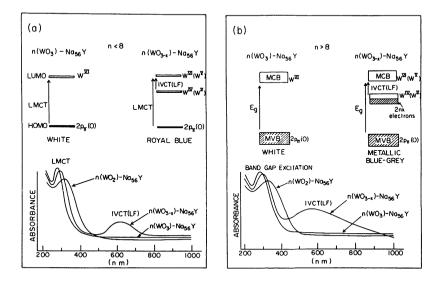

A) Doping

Temperature programmed thermal treatment of $n(WO_3)$ -Na₅₆Y (0 < n \leq 32) shows that dioxygen loss begins around 200°C to yield beautiful royal blue (0 < n \geq 8) or metallic blue-grey (8 \geq n \geq 32) or metallic grey (n = 32) materials with W:O = 1:2.5 at 300°C. Further dioxygen evolution continues between 300-400°C to eventually yield homogeneous white materials with W:O = 1:2. This process can be quantitatively reversed in O_2 at 300°C, recreating the original material $n(WO_3)$ -Na₅₆Y but by-passing the intermediate phase $n(WO_{2.5})$ -Na₅₆Y. These observations provide compelling evidence for the reductive-elimination oxidative-addition sequence of reactions:

A combination of PXRD, 29 Si/²⁷Al/²³Na MAS-NMR, Raman, Na⁺ cation Far-IR and νOH_{α} Mid-IR experiments performed on a range of $n(WO_{3-x})$ -Na₅₆Y samples demonstrate that just like the parent material $n(WO_3)$ -Na₅₆Y, the degree of crystallinity and integrity of the framework of the zeolite Y host material is maintained, little alteration in the host unit cell dimension is observed (around 24.69 Å for all samples), no bulk WO_{3-x} oxides are detected, and the WO_{3-x} guests remain internally confined and homogeneously dispersed throughout the *a*-cages of the host.

The optical reflectance spectra provide some interesting structure-electronic clues about the constitution of these materials. From inspection of some representative data for $n(WO_{3,r})$ -Na₅₆Y shown in Figure 2,

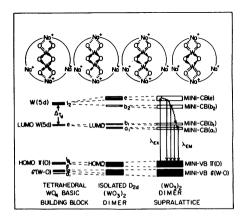

2. UV-visible reflectance spectra of $n(WO_{3-x})$ -Na₅₆Y for n < 8 and n > 8, where x = 0, 0.5, 1.

one spots two informative effects. An intense broad "blue" visible-band and a

red-shifted uv-band is observed on passing from $n(WO_3)-Na_{56}Y$ to $n(WO_{2.5})-Na_{56}Y$. This blue band broadens and the uv-band red shifts on passing from "isolated" (n < 8) to "coupled" (8 < n < 32) $WO_{2.5}$ materials. The blue band disappears and the uv-band-shifts even further on passing from $n(WO_{2.5})-Na_{56}Y$ to $n(WO_2)-Na_{56}Y$. The uv-band red-shifts again on passing from "isolated" (n < 8) to "coupled" (8 < n < 32) WO, materials, Figure 2.

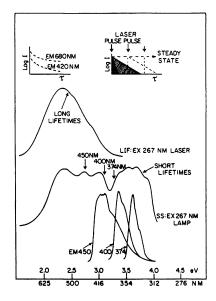

Recall (1) that the parents $n(WO_3)$ -Na₅₆Y display an O^{-II}(2p π) --> W^{VI}(5d) absorption edge around $E_g = 3.1$ -3.5 eV (computer fit, Kubelka Munk, $a^{da} = K(E-E_g)^{b}$) which is assigned to an interstate (HOMO-LUMO) LMCT excitation for the "isolated" (WO₃)₂ dimers ($n \leq 8$), Figure 3 and an interminiband (MVB-MCB) transition for the "coupled" (WO₃)₂ dimers ($8 \leq n \leq 32$), Figure 3.

3. Evolution of a qualitative miniband electronic scheme for a (WO₃)₂ dimer superalattice, 16(WO₃)-Na₅₆Y.

Some of the xenon lamp and laser induced emission/excitation spectra with time resolution obtained for $n(WO_3)$ -Na₅₆Y are depicted in Figure 4. The observation of considerable structure under the absorption-edge (450, 400, 374 nm excitation spectra), short (μ s, 450-300 nm) and long (ms, 680-500 nm) lifetime emissions, alerts one to the existence of complex coupling architecture in the MCB, possible "excitonic" emissions close to the miniband-gap energy, as well as "forbidden or trap" emissive states (Figure 4).

With the above information, the "blue" band in $n(WO_{2.5})$ -Na₅₆Y ($n \leq 8$) can be assigned to either a $W(IV) \rightarrow W(VI)$ intervalence-charge-transfer (IVCT) or a $W(V) \rightarrow W(V)$ ligand-field (LF) transition while the uv-band is ascribed to either a $O(-II) \rightarrow W(VI)$ or $O(-II) \rightarrow W(V)$ LMCT transition (3) (Figure 2). Where the clusters in $n(WO_{2.5})$ -Na₅₆Y first begin to couple (through space or zeolite framework) these IVCT (LF) and LMCT bands appear to broaden and/or red-shift. The IVCT (LF) band disappears in $n(WO_2)$ -Na₅₆Y ($n \leq 8$) with concomitant redshifting of the $O(-II) \rightarrow W(IV)$ LMCT band. Similar shifting and broadening effects occur in $n(WO_2)$ -Na₅₆Y at $n \geq 8$. Note that all $n(WO_{3-7})$ -Na₅₆Y samples (300-77K) are EPR silent but all yield high quality ²⁹Si/²⁷Al/²³Na MAS-NMR spectra (see later).

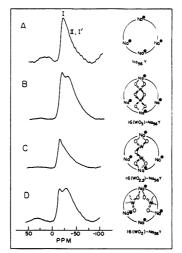

4. Selected photophysical properties of 16(WO₃)-Na₅₆Y

Adsorption-induced ²³Na MAS-NMR chemical shifts and Far-IR Na⁺ translatory mode frequency shifts provide direct and complimentary evidence for the anchoring of WO_{3-x} moieties to α -cage Na⁺ cations in all three samples $n(WO_{3-x})$ -Na₅₆Y (x = 0, 0.5, 1). Representative ²³Na MAS-NMR data which illustrate this point are shown in Figure 5.

In fully dehydrated Na₅₆Y one observes an intense asymmetric ²³Na resonance at -12 ppm which arises from a convolution of signals due to Na⁺ cations mainly in sites II, I, I' (2b). The most prominent narrow component centred at -12 ppm is ascribed to Na₁⁺ (six coordinate, hexagonal prism, essentially O_h symmetry, smallest second order quadrupole broadening). All other hexagonal six-ring Na⁺_{11,1} (a, β -cage respectively) have lower symmetries C_{3v}, are expected to exhibit more pronounced second order quadrupole broadening, and appear to fall within the high-field shoulder (-22 and -38 ppm) of the main ²³Na resonance, Figure 5. In 16(WO₃)-Na₅₆Y, the (WO₃), dimer perturbs one of the components of the Na₅₆Y high field shoulder around -22 ppm with a corresponding increase in its intensity (Figure 5). Similar effects exist in the ²³Na MAS-NMR spectra of both 16(WO_{2.5})-Na₅₆Y and 16(WO₂)-Na₅₆Y, where one notes that the perturbed ²³Na resonance is broader and less well pronounced in 16(WO_{2.5})-Na₅₆Y compared to 16(WO₂)-Na₅₆Y and 16(WO₃)-Na₅₆Y (Figure 5). Adsorption induced charge transfer to the terminal tungsten dioxo group of the imbibed WO3-x moieties from the Na_{II}^+ cations in $Na_{56}Y$ will serve to (a) decrease the shielding (b) lower the

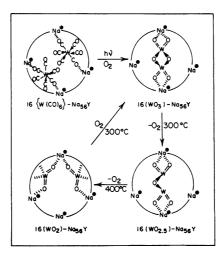

second order quadrupole broadening (c) reduce electric field gradients and (d) cutdown or eliminate site-exchange processes of those Na⁺ cations accessible to the act of anchoring. The primary effects of anchoring are then expected to be a shift of the *a*-cage ²³Na_{II} NMR resonance to lower fields with a concomitant enhancement of its intensity with increasing symmetry around the Na⁺_{II} site, Figure 5. This appears to describe the overall state-of-affairs for the series 16(WO_{3-x})-Na₅₆Y where in essence one "discovers" Na⁺_{II} through its selective anchoring and "locking" onto the WO_{3-x} moieties, Figure 5.

5. ²³Na MAS-NMR data for A) Na₅₆Y B) 16(WO₃)-Na₅₆Y C) 16(WO_{2.5})-Na₅₆Y and D) 16(WO₂)-Na₅₆Y

²³Na DOR-NMR studies are underway to explore these systems more thoroughly [4].

EXAFS structure analysis has been successfully applied to the precursor 8{W(CO)₆}-Na₅₆Y, photo-oxidation products 16(WO₃)-Na₅₆Y, 28(WO₃)-Na₅₆Y, 32(WO₃)-Na₅₆Y and thermal reductive-elimination products 16(WO_{2.5})-Na₅₆Y, 32(WO_{2.5})-Na₅₆Y, 16(WO₂)-Na₅₆Y, 28(WO₂)-Na₅₆Y and 32(WO₂)-Na₅₆Y (2c, 3). A summary of these experiments is shown in Figure 6. For the precursor, the EXAFS data confirm that the W(CO)₆ guest maintains its structural integrity with virtually no observable perturbations of the skeletal W- \underline{C} =O, R = 2.06 Å (2.058 Å), $N_c = 6.5(6.0)$, and ligand W-C= Ω , R = 3.21 Å (3.206 Å), $N_c = 6.8(6.0)$ bonds compared to those found for the same molecule in the free state (numbers in parenthesis). Estimates of uncertainty in reported R and N values are ± 0.02 λ and $\pm 20\%$ respectively. The EXAFS structure analysis results for the photooxidation products 16(WO₃)-Na₅₆Y, 28(WO₃)-Na₅₆Y and 32(WO₃)-Na₅₆Y are very similar, and display the presence of two short terminal W=O bonds (1.75 - 1.78) \dot{A}) and two long bridging W-O bonds (1.94 - 1.96 \dot{A}), together with a short distance to a second W (3.24 - 3.31 Å). This bond-length and coordination number information for n = 16, 28 and 32 samples is interpreted in terms of the formation of a "single kind" of tungsten(VI) trioxide dimer unit $(WO_3)_2$, most likely interacting with Na⁺_{II} cations (Far-IR/NMR) as shown in Figure 6. All the data for 16(WO₃)-Na₅₆Y support the contention of a uniform array of single-size and shape $(WO_3)_2$ dimers housed in the 13 Å supercages of the zeolite Y host. The sequential addition of WO₃ units to the 16(WO₃)-Na₅₆Y sample to eventually form "fully" filled 32(WO₃)-Na₅₆Y appears to increase the $(WO_3)_2$ dimer population, causing a build-up of *a*-cage dimers-of-dimers { $(WO_3)_2$ } (Figure 1),

6. Summary of structures and anchoring schemes for a-cage encapsulated precursor 16{W(CO)₆}-Na₅₆Y as well as its photo-oxidation product 16(WO₃)-Na₅₆Y and corresponding reductive-elimination, oxidation-addition products 16(WO₃₋₇)-Na₅₆Y.

rather than further cluster growth to trimers $(WO_3)_3$ and/or tetramers $(WO_3)_4$.

The presently observed EXAFS data set for the $16(WO_{2.5})$ -Na₅₆Y sample was not of sufficient quality (5) to permit reliable determination of the oxygen distances or coordination numbers. However, it is valid to make the qualitative statement that W-W backscattering was observed, hence leading to the conclusion that the tungsten oxide moiety in this case is at least dimeric, like that found in $16(WO_3)$ -Na₅₆Y. Interestingly the EXAFS data of the $32(WO_{2.5})$ -Na₅₆Y sample are very similar to those of its parent $32(WO_3)$ -Na₅₆Y showing two kinds of short/long W = O/W-O (1.75 - 1.95 Å) bond, but now signals a short distance to three other W(3.30 Å). The bond lengths and coordination numbers for both types of oxygen and tungsten, are fully consistent with a "tetrameric" structure wherein the four tungsten atoms lie at the apices of a tetrahedron. The EPR silence of the $16(WO_{2.5})$ -Na₅₆Y dimer implies the existence of either a spin-paired singlet or a rapidly relaxing triplet electronic configuration for the two possible dimer formulations, namely either single valent ZONa...O₂W(V)(μ -O)W(V)O₂...NaOZ or mixed valence ZONa...O₂W(IV)(μ -O)W(VI)O₂...NaOZ. The ability to collect high quality ²⁹Si, ²⁹Al, ²³Na MAS-NMR spectra for this sample favours the former spun paired diamagnetic assignment. Much more work, in particular XPS, is needed to clarify this fascinating point.

The EXAFS data of the $16(WO_2)-Na_{56}Y$ material are quite distinct to that of the other two samples, indicating only one W-O shell with $R = 1.81 \text{ Å } N_o = 4.1$ which is very similar to that of the Na_2WO_4 reference compound. There is no evidence of W-W backscattering in the $16(WO_2)-Na_{56}Y$ material. The EXAFS results for $28(WO_2)-Na_{56}Y$ and $32(WO_2)-Na_{56}Y$ are essentially identical to those of $16(WO_2)-Na_{56}Y$. The best model for these intrazeolite WO_2 materials is a 4-ring oxygen framework coordination site to the tungsten(IV) centre of a low spin monomeric WO_2 moiety, of which the terminal W=O oxygens interact with Na^+_{II} as indicated in Figure 6. This is the best way to reconcile the oxygen coordination number, tungsten(IV) oxidation state and Na^+ anchoring interaction clues for $n(WO_2)-Na_{56}Y$ (where n = 16, 28, 32) obtained from EXAFS, UV-VIS, FAR-IR, EPR and MAS-NMR spectroscopies.

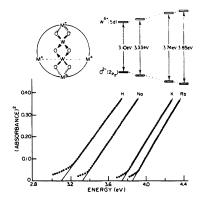

B) Band-Gap Engineering

The feasibility of fine-tuning the band-gap of the $16(WO_2)-M_{ee}Y$ supralattice is illustrated in Figure 7. On moving from M = H to Cs at the two extremes one observes a blue-shift of the absorption edge (computer fit, Kubelka Munk, a^{da} = $K(E-E_{\alpha})^{\prime h}$) of about 0.75 eV. E_a values estimated in this way are H(3.10 eV), Li(3.53 eV), Na(3.33 eV), K(3.74 eV), Rb(3.85 eV), Cs(3.85 eV). Assuming the $(WO_3)_2$ dimer structure is maintained across the series M = H, Li, Na, K, Rb, Cs, one can envisage that enhanced local electrostatic fields arising from the presence of M_{II}^+ cations and experienced by each $(WO_3)_2$ dimer will serve to (i) deplete the (WO₃), of valence electron density (ii) weaken skeletal W-O bonds, (iii) destabilize the $O^{-II}(2p\pi)$ and stabilize the $W^{VI}(5d)$ MVB and MCB respectively, with a concomitant decrease in the band-gap (LMCT) energy, Figure 7. Because of the variation in population of, and distance between M_{π}^{+} cations, one does not expect the cation dependence of the miniband gap energy to be a straightforward function of ionic potential across the M = H, Li, Na, K, Rb, Cs series. Thus amonotonicity in E_g for Li₅₆Y and Na₅₆Y might relate to the known desire of ${\rm Li}_{\pi}^+$ to reside in the plane of oxygen 6-rings. Spatial constraints for $Rb_{56}Y$ and $Cs_{56}Y$ (90% $M^+{}_{II}$, $M^+{}_{III}$) could be the cause of their similar E_g values. The "special" position of $H_{56}Y$ in this series is probably related to the "dual" involvement of hydrogen-bonding (ZOH_{α} to terminal W=O) and protonation $(ZOH_{\beta}$ to bridging W-O) found for $(WO_3)_2$ in 16(WO₃)-H₅₆Y, (1). Rietveld PXRD structure refinements and EXAFS structure analyses are currently underway for the entire n(WO₃)-M₅₆Y series in order to check the validity of the preliminary results and ideas presented above.

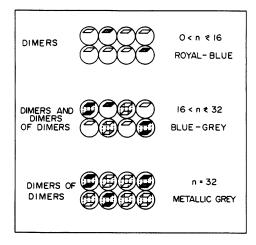

Summary

A simple chemical means of injecting electrons and holes into $n(WO_{3-x})-Na_{56}Y$ has been achieved ($0 \le x \le 1$). The method is applicable to isolated (WO_{3})₂

dimers, coupled $(WO_3)_2$ dimers and a supralattice of coupled $\{(WO_3)_2\}_2$ dimers-ofdimers imbibed in the *a*-cage of the zeolite Y host lattice. An illustration of this concept is shown in Figure 8.

7. Experimental uv-visible absorption edges of a $16(WO_3)-M_{56}Y$ supralattice, where M = H, Na, K, Rb together with the best computer fit to the absorption index of an allowed-direct band gap transition, $a^{da} = K(E - E_g)^{V_2}$. Inserts qualitatively illustrate the MVB/MCB energy levels for $16(WO_3)-M_{56}Y$.

Intracavity and intercavity connectivity (coupling) in n(WO_{3-x})-Na₅₆Y for x < 0.5.

Through alterations of the local electrostatic fields experienced by the $(WO_3)_2$ dimers, achieved by varying the ionic potential of constituent supercage cations, one is provided with a novel means of fine-tuning the miniband-gap of a tungsten(VI) oxide supralattice. Therefore cluster size, composition and intrinsic electrostatic field effects can be used to "chemically manipulate" (engineer) the doping and band architecture of organized assemblies of intrazeolite $(WO_3)_2$ dimers.

Acknowledgements

We wish to acknowledge (GAO, PMM) the Natural Sciences and Engineering Research Council (NSERC) of Canada's Operating and Strategic Grants Programmes for generous financial support of this work. Sö expresses his gratitude to the Middle East Technical University for granting him an extended leave of absence to conduct his research at the University of Toronto. K.M. and T.B. acknowledge partial funding for this work from the donors of the Petroleum Research Fund administered by the American Chemical Society. The operational funds for NSLS beamline X-11A are provided by DOE Grant Number DE-AS0580ER10742 (KM, TB) and NSERC (GAO). Supplies of high quality zeolites from Dr. Edith Flanigen at Union Carbide, Tarryton, N.Y. are gratefully appreciated. Dr. Heinz Robota of Allied Signal is acknowledged for his assistance with the collection and analysis of EXAFS data. The assistance of Dr. Andrew Holmes and Mr. Alex Kuperman with various aspects of this project are also most deeply appreciated.
