HEMODYNAMIC AND RENAL EFFECTS OF ATRIAL NATRIURETIC PEPTIDE IN NORMAL MAN

Depts. of Medicine and Biochemical Endocrinology, Medical University  
Lübeck, and Dept. of Medicine, University München

We studied the hemodynamic and renal actions of atrial natriuretic peptide  
( $\alpha$ -hANP) in 7 healthy volunteers.

Methods: 200  $\mu$ g of  $\alpha$ -hANP were given as an intravenous bolus injection. M-mode-echocardiography was performed and serum levels of ANP and cGMP as well as cGMP-, sodium- and potassium excretion were determined.

Results: Within 2 min, a transient heart rate increase of 34% together with a fall of mean arterial blood pressure of 11% was observed. Stroke volume increased from  $77.5 \pm 15.1$  to  $90.3 \pm 102$  ml and cardiac index from  $2.44 \pm 0.41$  to  $2.88 \pm 0.41$  l/m<sup>2</sup>/min. Ejection fraction rose from  $62.9 \pm 1.8$  to  $73.5 \pm 3.8\%$  ( $p < 0.01$ ). Hemodynamic changes were most pronounced from 10 to 15 min after injection and reached baseline values another 15 min later. Serum ANP rose 20fold; exogenous ANP had cleared after 45 min from the circulation. cGMP rose 8fold within the first 15 min and normalized after 1 hour. Correspondingly, urinary cGMP excretion increased nearly 8fold. Urine volume increased 9fold, sodium excretion 5fold and potassium excretion doubled. These renal effects - in contrast to the hemodynamic changes - showed a maximum within the first 30 min, but were still present for at least 90 min later. No severe side effects were observed.

Conclusions: Improved myocardial performance together with sustained diuresis and natriuresis may be of therapeutical benefit in the treatment of congestive heart failure. The role of cGMP as a marker for ANP action is confirmed.
