Attempts to prepare the hitherto unknown Se₆²⁺ cation by the reaction of elemental selenium and Ag[A] ([A][−] = [Sb(OTeF₅)₆][−], [Al(OC(CF₃)₃)₄][−]) in SO₂ led to the formation of [(OSO)Ag(Se₆)Ag(OSO)] [Sb(OTeF₅)₆]₂ **1** and [(OSO)₂Ag(Se₆)Ag(OSO)₂] [Al(OC(CF₃)₃)₄]₂ **2a**. **1** could only be prepared by using bromine as co-oxidant, however, bulk **2b** (**2a** with loss of SO₂) was accessible from Ag[Al(OC(CF₃)₃)₄] and grey Se in SO₂ (chem. analysis). The reactions of Ag[MF₆] (M = As, Sb) and elemental selenium led to crystals of 1/∞{[Ag(Se₆)]_∞[Ag₂(SbF₆)₃]_∞} **3** and {1/∞[Ag(Se₆)Ag]_∞}[AsF₆]₂ **4**. Pure bulk **4** was best prepared by the reaction of Se₆[AsF₆]₂, silver metal and elemental selenium. Attempts to prepare bulk **1** and **3** were unsuccessful. **1–4** were characterized by single-crystal X-ray structure determinations, **2b** and **4** additionally by chemical analysis and **4** also by X-ray powder diffraction, FT-Raman and FT-IR spectroscopy. Application of the PRESTO III sequence allowed for the first time ¹⁰⁹Ag MAS NMR investigations of **4** as well as AgF, AgF₂, AgMF₆ and {1/∞[Ag(I₂)]_∞}[MF₆] (M = As, Sb). Compounds **1** and **2a/b**, with the very large counter ions, contain isolated [Ag(Se₆)Ag]²⁺ heterocubane units consisting of a Se₆ molecule bicapped by two silver cations (local D_{3d} sym). **3** and **4**, with the smaller anions, contain close packed stacked arrays of Se₆ rings with Ag⁺ residing in octahedral holes. Each Ag⁺ ion coordinates to three selenium atoms of each adjacent Se₆ ring. **4** contains [Ag(Se₆)]⁺ stacks additionally linked by Ag(2)⁺ into a two dimensional network. **3** features a remarkable 3-dimensional [Ag₂(SbF₆)₃][−] anion held together by strong Sb–F...Ag contacts between the component Ag⁺ and [SbF₆][−] ions. The hexagonal channels formed by the [Ag₂(SbF₆)₃][−] anions are filled by stacks of [Ag(Se₆)]⁺ cations. Overall **1–4** are new members of the rare class of metal complexes of neutral main group elemental clusters, in which the main group element is positively polarized due to coordination to a metal ion. Notably, **1** to **4** include the commonly metastable Se₆ molecule as a ligand. The structure, bonding and thermodynamics of **1** to **4** were investigated with the help of quantum chemical calculations (PBE0/TZVPP and (RI-)MP2/TZVPP, in part including COSMO solvation) and Born–Fajans–Haber-cycle calculations. From an analysis of all the available data it appears that the formation of the usually metastable Se₆ molecule from grey selenium is thermodynamically driven by the coordination to the Ag⁺ ions.

Introduction

Numerous molecular cyclic sulfur and selenium allotropes E_n (E = S: n = 6–15, 18, 20 etc.; E = Se: n = 6, 7, 8) that are isolable at r.t. have been prepared and structurally characterized. Molecular S₈ is the most stable form of sulfur and the stability of the selenium allotropes increases in the order: Se₇ < Se₆ < Se₈ < Se_∞.^{1–5} Metastable chair-Se₆ was inserted into mordenite, Zeolite Y and a SiO₂ matrix.^{6–8} Hexagonal Te_∞ is the only stable allotrope of tellurium. Salts of the isolated molecular diamagnetic

homopolyatomic cations S_n^{2+} ($n = 4, 8, 19$), Se_n^{2+} ($n = 4, 8, 10, 17$) and Te_n^{m+} ($n = 4, 6, 7, 10, m = 2; n = 8, m = 2, 4$) contain positively charged rings formed upon oxidation of the elements with non basic anions.^{9–17} Few examples where a partial positive charge is induced onto an electronegative main group element cluster on coordination to a metal ion like Ag^+ are known, and require that the counterion is weakly basic like $[MF_6]^-$ ($M = As, Sb$), $[Sb(OTeF_5)_6]^-$ or the $[Al(OR_F)_4]^-$ aluminates ($R_F = C(CF_3)_3, C(H)(CF_3)_2$): e.g. $[Ag(S_8)_n]^+$,^{18,19} $[Ag(P_4)_n]^{+20-22}$ ($n = 1, 2$), $[Ag(I_2)^+]_{\infty}$ ²³ and $[Ag(P_4S_3)_n]^{+24,25}$ ($n = 1-3$). One of us prepared and characterized the cations $[Se_6I^+]_{\infty}$ and $[Se_6I_2]^{2+}$,^{26,27} which can be viewed as containing Se_6 coordinated to “I⁺”. Other related selenium cations include $[Se_6Se_2Cl]^+$ ²⁸ and $[Ph_2Se_6]^{2+}$.²⁹ There are also some examples of hexaselenium, heptaselenium and nonaselenium coordinated to a transition metal ($PdCl_2(Se_6)$,³⁰ $PdBr_2(Se_6)$,³⁰ $(AgI)_2Se_6$,³¹ $Re_2I_2(CO)(Se_7)$ ^{32,33} and $Rh_2Se_3Cl_6$ ³⁴). Salts containing cationic stacks of $[Rb(Se_8)^+]_{\infty}$ ³⁵ and $[Rb(Se_6)_2^+]_{\infty}$,³⁶ in which a weak interaction between Rb^+ and the selenium rings was postulated, are known. Crown-shaped Te_8 rings were stabilized in Cs_3Te_{22} in the coordination sphere of the caesium atom, which is surrounded by a cube of tellurium atoms from two Te_8 rings.³⁷ $AgTe_3[AsF_6]$ has been reported but no structural characterization was presented.³⁸

Herein we report on reactions of grey selenium and $Ag[Al]^-$ ($[Al]^- = [Sb(OTeF_5)_6]^-$,^{39–41} $[Al(OC(CF_3)_3)_4]^-$, $[AsF_6]^-$ and $[SbF_6]^-$) forming $[(OSO)Ag(Se_6)Ag(OSO)][Sb(OTeF_5)_6]_2$ **1**, $[(OSO)_2Ag(Se_6)Ag(OSO)_2][Al(OC(CF_3)_3)_4]_2$ **2a**, $1/\infty\{[Ag(Se_6)]_{\infty}[Ag_2(SbF_6)_3]_{\infty}\}$ **3** and $\{1/\infty[Ag_2(Se_6)]_{\infty}\}[AsF_6]_2$ **4**. Each of these salts contains partially oxidised metastable hexaselenium rings in a chair conformation coordinated to Ag^+ . The crystal structures of **1**, **3** and **4** were already published in 2004 in a short communication.⁴²

Results and discussion

Synthesis of single crystal **1** and attempts to prepare bulk **1**

Attempts to prepare $Se_6[Sb(OTeF_5)_6]_2$ containing the hitherto unknown Se_6^{2+} dication (cf. Te_6^{2+})¹² by the reaction of elemental selenium and $Ag[Sb(OTeF_5)_6]$ in SO_2 (molar ratio 3–7 Se : 1 Ag^+) led to $Se_{10}[Sb(OTeF_5)_6]_2$ as the only identifiable selenium product (⁷⁷Se-NMR). The oxidation power of the reactants was increased by the addition of bromine with the hope that the reaction would proceed according to eqn (1).

The reaction gave yellow needle-like crystals, which were unsuitable for X-ray diffraction studies, and from which Raman and ⁷⁷Se NMR spectra could not be obtained. However, storage of an oily reaction product for three months at ambient temperature yielded large yellow-orange cubes of **1** (X-ray structure). We were unable to prepare **1** directly from selenium and $Ag[Sb(OTeF_5)_6]$, but always observed the formation of Se cations in SO_2 solution by ⁷⁷Se-NMR spectroscopy (Se_{10}^{2+} , and upon cooling to -70°C also small amounts of Se_8^{2+}).

Syntheses of **2a/b**, **3**, and **4**

A direct synthesis of the closely related compound **2a** became possible with the use of $Ag[Al(OC(CF_3)_3)_4]$ and grey selenium powder in SO_2 (eqn (2)).

During the reaction the greyish suspension turned increasingly green (maximum at two hours) then later became brown-orange. This observation is related to the reaction leading to **1**: the ⁷⁷Se-NMR spectra of which indicated the intermediate formation of brown Se_{10}^{2+} as well as small amounts of (green) Se_8^{2+} . Attempts to directly detect these Se-dications in reactions leading to **2a** by solution ⁷⁷Se-NMR spectroscopy were unsuccessful due to the exceedingly low concentrations of the intermediate species. The observed signals of NMR reactions with the suitable stoichiometry to give **2a** at $\delta^{77}\text{Se} = 1074.4, 982.3$ and 862.3 in a saturated SO_2 solution of **2a** could neither be assigned to free Se_6, Se_7, Se_8 rings nor to selenium cations ($Se_4^{2+}, Se_8^{2+}, Se_{10}^{2+}$). The spectra are characterised by a poor signal to noise ratio even after 27000 scans at 298 and 233 K (delay 5 s, acquisition time 0.84 s; original spectra deposited in the ESI†). This may be attributed to underlying dynamic exchange processes, which is supported by DFT-calculations including COSMO solvation (see below).

Orange needle shaped crystals of **2a** were obtained reproducibly by cooling the crude oily product to 2°C (yield 67% crystalline material). Attempts to obtain Raman spectra of **2a** failed even at 100 K and with low laser energy due to fluorescence and sample decomposition in the Laser beam. Samples of **2b** gave X-ray powder patterns of microcrystalline materials with large cell parameters that are different to those simulated with the cell parameters of **2a** ($S10^\ddagger$). An elemental analysis of crystals of the same batch had only minor sulfur content (exp. 0.17%), but otherwise was in agreement with the formulation of a salt $[Ag_x(Se_6)(SO_2)_y][Al(OC(CF_3)_3)_4]_2$ with x being < 0.1 . Thus, upon isolation of **2b**, probably the weakly bound SO_2 in **2a** is almost completely lost.

Small amounts of single crystals of **3** and **4** were obtained by the reactions of a large excess of $Ag[SbF_6]$ and $Ag[AsF_6]$ with selenium powder with short reaction time in liquid SO_2 , followed by filtration and formation of crystals of **3** and **4** after a few minutes. It is possible that $[Ag_x(Se_6)(SO_2)_y]^{x+}$ intermediates ($x = 1$ and $2; y = 0-4$) are present in a concentrated SO_2 solution of $Ag[MF_6]$, leading to the insoluble $[MF_6]^-$ salts of the polymeric $[Ag(Se_6)^+]_n$ cations (see calculations below).

Attempts to prepare bulk **3**

Several reactions of various stoichiometries with selenium in both powder as well as pellet form and $Ag[SbF_6]$ were carried out (ESI S1.1 and S1.2†) in attempts to prepare pure **3** in bulk quantities. The powder diffraction patterns of the resulting insoluble products do not clearly fit or contain the calculated pattern based on the single X-ray crystal structure of **3**; the nature of the insoluble products is not clear at this time. Their Raman spectra are similar, and show similar Se–Se and Se–Ag–Se stretching frequencies (ESI S1.3/S1.5†). The reaction of $Ag[SbF_6]$ with excess Se pellets gave a solid with a chemical analysis consistent with the

formulation $\text{Ag}(\text{Se}_6)[\text{SbF}_6]$. In a large excess of $\text{Ag}[\text{SbF}_6]$, solid **3** was isolated from the solution (see above). It is likely that **3** is thermodynamically unstable in the presence of liquid sulfur dioxide with respect to the insoluble $\{1/\infty[\text{Ag}_2(\text{Se}_6)]_\infty\}[\text{SbF}_6]_2$, the $[\text{SbF}_6]^-$ analogue of **4**, and very soluble $\text{Ag}[\text{SbF}_6]$ (eqn (3)). Further loss of soluble $\text{Ag}[\text{SbF}_6]$ could also be envisaged (eqn (4)).

The ^{109}Ag solid state NMR confirmed the complexity of the $\text{Se}/\text{Ag}[\text{SbF}_6]$ reactions (ESI S1.7†).

Synthesis of bulk **4**

Bulk **4** was prepared by the reaction of excess $\text{Ag}[\text{AsF}_6]$ and Se pellets (eqn (5)). Unreacted Se pellets were manually separated from the yellow insoluble product, from which a good quality Raman spectrum (ESI†), a ^{109}Ag -MAS-NMR (-42 , -220 ppm) (Fig. 6), and a ^{19}F MAS-NMR spectrum (see Table 3) were obtained. The empirical formula of the insoluble product based both on weight changes and on chemical analysis, is in good accordance with that established from the single crystal structure determination of **4**. The reaction of $\text{Ag}[\text{AsF}_6]$ and excess Se pellets led to an insoluble product of a similar formulation. However, its Raman spectrum (ESI S1.3/S1.5†) gave an additional peak (156 cm^{-1}), which might arise from an impurity or from a different phase of similar composition.

An alternative route to bulk **4** was provided by the reaction of $\text{Se}_4[\text{AsF}_6]_2$, silver metal and elemental selenium at room temperature (eqn (6)).

The Raman and IR spectra of the yellow insoluble product were identical to those from the reaction of excess $\text{Ag}[\text{AsF}_6]$ with Se pellets (ESI S1.3/S1.5†). The X-ray powder diffraction patterns of the yellow insoluble product obtained by the two routes were identical and very similar to that calculated from the single crystal structure of **4** (ESI S1.8†).

Crystal structures

All crystal structures **1–4** (Table 1, Fig. 1 and ESI S2†) feature the remarkable, ideally D_{3d} -symmetric, $[\text{Ag}_2\text{Se}_6]$ -heterocubane unit, derived from a Se_6 ring in chair conformation which is biccapped by two silver atoms.

The bond distances and angles of the Se_6 rings are quite similar to that in elemental Se_6 (see Table 1). The structure²⁶ of $[\text{Se}_6\text{I}_2]^{2+}$ can be considered as a less symmetric relative, in which symmetrically coordinating Ag^+ is substituted by asymmetrically interacting I^+ (see ESI S2.1.3†). The heterocubane $[\text{Ag}_2\text{Se}_6]^{2+}$ structure is related to that of the Nb_2Sn_6 moiety in $[\text{Nb}_2\text{Sn}_6(\text{C}_6\text{H}_5\text{Me})_2]^{2-43}$ (S2.1.2†).

Structures containing isolated $[\text{Ag}_2(\text{Se}_6)]$ heterocubane units

Each silver atom in **1** is coordinated to one SO_2 molecule, which is threefold disordered maintaining the local D_{3d} symmetry (see ESI S2.1†). **1** and **2a** contain discrete $[(\text{OSO})\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})]^{2+}$ and $[(\text{OSO})_2\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})_2]^{2+}$ dications and $[\text{Sb}(\text{OTeF}_5)_6]^-$ and $[\text{Al}(\text{OC}(\text{CF}_3)_3)_4]^-$ counter ions which have typical structures and (resolved) disorder inherent to these ions. See ESI for a comparison of anion bond distances and angles, and drawings of the disorder. The packing of ions is in agreement with the radius ratio rules (see ESI S2.1†). The weak cation anion contacts (distances and valency units^{44,45} (v.u.) given in Table 1), imply positive charge on all atoms in the $[\text{Ag}_2\text{Se}_6]^{2+}$ heterocubane in **1** and **2a**. The $\text{Ag}^+ \dots \text{OSO}$ distance and v.u. in **1** ($2.28(3)\text{ \AA}$) is very similar to that in $\text{OSO} \dots \text{Ag}[\text{Al}(\text{OC}(\text{CF}_3)_3)_4]$ (ESI S2.1.7†), which was shown to be almost completely an ionic interaction as was the interaction in gaseous $\text{Ag}^+(\text{OSO})_n$ ($n = 1, 2$).⁴⁶ The two $\text{OSO} \dots \text{Ag}^+$ distances in **2a** are similar to **1** (Table 1) and also highly ionic. Thus, both **1** and **2a** contain discrete $[\text{Ag}_2\text{Se}_6]^{2+}$ heterocubane dications. One threefold disordered SO_2 per Ag in **1** leads to a $[\text{Ag}_2\text{Se}_6]^{2+}$ structure with local D_{3d} symmetry. **2a** contains two SO_2 per Ag^+ as well as a secondary contact to the silver atom of the adjacent cation (see Fig. 2) leading to an overall C_i -symmetry of $[\text{Ag}_2\text{Se}_6]^{2+}$ in **2a**. Additional weak $\text{Ag}^+ \dots \text{F}$ contacts in **1** and **2a** lead to an $(5 + 2)\text{ Ag}^+$ coordination, as is common in more ionic Ag^+ complexes⁴⁷ (ESI S2.1/S2.2†).

Structures containing polymeric $[\text{Ag}(\text{Se}_6)]_\infty$ stacks

3 is constructed from a 1D $[\text{Ag}(\text{Se}_6)]_\infty$ cationic coordination polymer encapsulated by a honeycomb-like array of $[\text{Ag}_2(\text{SbF}_6)_3]^-$ anions (Fig. 1 and 3).

To the first order of approximation, the $[\text{Ag}(\text{Se}_6)]_\infty$ cation can be viewed as a stack of closed packed Se_6 rings with Ag^+ residing in the octahedral holes (see also ESI S2.3). Some related stacks can be found in the literature, e.g. $[\text{Rb}(\text{Se}_8)]_\infty^{35}$ (see ESI S2.3.7a) or $[\text{Cs}(\text{Te}_8)]_\infty^{37}$. There are weak $\text{F} \dots \text{Se}$ contacts as well as one fluorine $\text{F} \dots \text{Ag}^+$ contact (Table 1) at $3.095(9)\text{ \AA}$, which slightly distorts the ideal D_{3d} symmetry of the $[\text{Ag}_2\text{Se}_6]^{2+}$ fragment in the stack (see Fig. 1) and increases the coordination number of Ag^+ to seven. A detailed description of the $[\text{Ag}_2(\text{SbF}_6)_3]^-$ anion is given in the ESI (S2.3). It forms hexagonal channels that include the 1D $[\text{Ag}(\text{Se}_6)]_\infty$ stacks. Six silver atoms, that are bridged by six $[\text{SbF}_6]^-$ units, reside at each corner of the hexagonal cavity.

4 consists of similar $[\text{Ag}(\text{Se}_6)]_\infty$ stacks down the c -axis, cross linked by silver (Ag_2) ions into infinite two dimensional networks in the ac -plane separated by $[\text{AsF}_6]^-$ anions (see Fig. 1 and 4). The two cross linking $\text{Ag}–\text{Se}$ bond lengths are shorter ($2.688(2)\text{ \AA}$) than those in the stack ($2.941(3)$, $2.927(2)\text{ \AA}$; 6 per Se_6).

The cross-linked $[\text{Ag}(\text{Se}_6)]_\infty$ chains are related to those of $\text{PdX}_2(\text{Se}_6)$ ($X = \text{Cl}, \text{Br}$)³⁰ in which Se_6 is η^1 -coordinated to Pd forming infinite chains. Normally chalcogen rings coordinate above the ring or in a lateral fashion,^{32,33} but here both coordination modes are realised in a 2D structure for which only one related example $[\text{Rh}_2(\text{O}_2\text{CCF}_3)_4]_3(\text{S}_8)_2$ is found in the literature.⁴⁸ In **4** no silver fluorine contacts are found to the Ag^+ in the $[\text{Ag}(\text{Se}_6)]_\infty$ stack, but Ag_2 is involved into multiple fluorine contacts, two from each of the four adjacent anions ($\text{Ag}_2\text{-F1 } 2.689(6) (\times 4)$, $\text{Ag}_2\text{-F2 } 3.053(6) (\times 4)\text{ \AA}$).

Table 1 Selected structural parameters of crystal structures **1**, **2a**, **3** and **4**, calculated structures **A–C** (PBE0/TZVPP) and elemental Se₆. Bond valences⁴⁵ in italics. ^a See diagram.

All cations, regardless of whether they are more or less isolated as in **1** and **2a**, or if they are polymeric as in **3** and **4** bear numerous Se–F contacts ranging from 2.912 to 3.384 Å, indicating that positive charge is delocalized from the silver atoms to the selenium rings (see Table 1 below). All structural parameters of **1** to **4** as well as Se₆ and other related (in part calculated) compounds are compared in Table 1 below and more extensively in the ESI (see S2†).

Quantum chemical calculations

To gain deeper insight into the structural features and bonding properties of these compounds various structures were calculated at different levels (See Table 1, Fig. 5, ESI†). The key structural unit of compounds **1** to **4** is the *D*_{3d} symmetric [Ag₂Se₆]²⁺ cation **A**, which is a building block to all structures discussed here. This unit was calculated at BP86/SVP, PBE0/TZVPP and (RI-)MP2/TZVPP levels to find an appropriate method for the structure calculation. Pure DFT with the rather small SVP basis set underestimates the Se–Se and Ag–Se distances significantly as this

method intrinsically neglects dispersion. Hybrid DFT PBE0 with a larger triple ζ basis set leads to acceptable bonding parameters compared to the crystal structures. The Se–Se distances are slightly too long, but the Ag–Se distances are within the experimental error (longer distances in the crystal structures arise from coordination and deviation from the ideal *D*_{3d}-symmetry (e.g. crystal structure of **2a**). MP2 shows Se–Se distances which fit exactly the experimental values, but overestimated electron correlation leads to overly short Ag–Se distances. Thus, we decided to further investigate the system mainly using the PBE0/TZVPP method.

To prove the influence of further coordination to the silver atoms several other structures, inter alia [(OSO)Ag(Se₆)Ag(OSO)]²⁺, [(OSO)₂Ag(Se₆)Ag(OSO)₂]²⁺ and cationic fragments **B** and **C**—derived from crystal structures **3** and **4**—were optimised. The bond distances and angles of structures **A–C** (Table 1) are comparable to those found in the solid state and are therefore not discussed in detail. In contrast to this, the optimised structures **D** and **E** that were taken from the cation structures of **1** and **2a** show a significant deviation from the solid state arrangements (Fig. 5).

Fig. 1 Single crystal X-ray structures of cations in **1**, **2a**, **3** and **4**. Atomic distances in Å, and angles in degrees. The thermal ellipsoids are drawn at the 50% probability level.

Fig. 2 Section of the cation stack in **2a** with Ag–O contacts (dashed lines/distance in Å). Thermal ellipsoids are shown with 50% probability.

The minimum geometry for $[(OSO)_2Ag(Se_6)Ag(OSO)_2]^{2+}$ **D** obtained by BP86/SVP leads to a structure that is significantly different from the solid state structure of **1** obtained *via* single crystal X-ray crystallography. Here only one η^1 -silver–selenium bond is found ($d = 2.532$ Å), two other contacts ($d = 3.845$ Å)

give a structure much closer to the C_{2h} -symmetric $[Se_6I_2]^{2+}$ -unit. However, if the calculation is carried out with the more balanced PBE0/TZVPP hybrid HF-DFT-method, this effect on the bond lengths is attenuated. Three distances range from 2.782–3.045 Å, which are closer to, but still different from, the crystallographic

Fig. 3 a) A view of **3** down the *c*-axis; b) detail of one 1D polymeric $[\text{Ag}(\text{Se}_6)]_n$ strand of **3** along the *c*-axis.

values by up to 0.15 Å. MP2/TZVPP gives similar results with slightly shorter bond lengths. The Ag–(OSO) coordination in **D** reduces the symmetry of the central $[\text{Ag}_2\text{Se}_6]$ -unit to C_i in the gas

Fig. 5 Calculated structures **D** $[(\text{OSO})\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})]^{2+}$ and **E** $[(\text{OSO})_2\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})_2]^{2+}$. Values: in **bold** gas phase structures (PBE0/TZVPP); in *italics* structures optimised including COSMO solvation PBE0/TZVPP (COSMO; $\epsilon_r = 16.3$); bond length in Å, angles in degrees. Experimental distances of the cations of structures **1** and **2a** are given in parentheses.

Fig. 4 A portion of **4** projected down the *c*-axis.

phase. Due to size restrictions, the calculation of the coordination of two additional SO_2 molecules in $[(\text{OSO})_2\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})_2]^{2+}$ **E**⁵⁰ was only carried out at the PBE0/TZVPP level. When comparing the calculated structure of **E** to **2a**, one has to take into consideration that the experimental structure is a 1D coordination polymer and not an isolated structure (Fig. 2). In the gas phase one Ag–Se distance (3.295 Å) of **E** is rather long, which leads to the reduced η^2 -silver-selenium coordination. Overall, the calculated gas phase structures of **D** and **E** show significant deviations from the crystal structures. Here the question emerged whether the structural features of dicationic **1** and **2a** were attainable by gas phase calculations in the absence of the solid state environment. Therefore, it appeared wise to include medium effects, as the lattice of an AB_2 salt may greatly influence the structure due to its inherent (but unknown) dielectric constant. A simple way to

Phys.*, **1976**, *64*, 4156. ^f Calculated frequencies below 85 cm⁻¹ are not shown (see electronic supplementary information: Raman). ^g Peak intensities were determined by estimating the area (for Raman) and height (for IR) of peaks. ^h There is some combination of the SeSe stretching bands: 512 (intensity: 0.01, origin: 275 + 234), 491 (0.01, 256 + 234), 467 (0.01, 234 × 2), 442 (0.06, 275 + 172). ⁱ The AsF₆⁻ assignments are based on ideal O_h symmetry and for Se₆ on ideal D_{3d} symmetry. The actual symmetry in O₂AsF₆ in **4** is O_h, however C₂ in **4**, and C₁ in (Se₆I)_∞-nAsF₆, thus leading to additional bands. ^j Fragment A, (D_{3d}), Fragment B (C₁), no selection rules, Fragment C (C_{2h}). Idealized symmetries which may differ from real solid state. Additional or less bands may occur in the synthesized compounds.

include medium effects and to overcome the Coulomb repulsion between the two silver ions in the gas phase is to employ the COSMO solvation model. Both **D** and **E** were optimised at the PBE0/TZVPP level with the COSMO⁵¹ model (ε_r = 16.3 (SO₂ 298 K⁵²)). When these medium effects are included, the [Ag₂Se₆]²⁺-unit in **D** turns almost D_{3d} symmetric (d_{AgSe} = 2.866, 2.868, 2.886 Å) within 0.02 Å from the crystal structure **1**. In **E** one longer bond at 3.109 Å and two shorter bonds at 2.792 and 2.914 Å give an asymmetric η³-coordination to the Ag⁺ ion. Overall it appears that the inclusion of medium effects leads to a better agreement between the experimental and calculated structures.

Vibrational spectra of **4**

The Raman spectrum (ESI S4†) shows the bands attributable to the polymeric [Ag₂(Se₆)²⁺]_∞ cation and that of an isolated [AsF₆]⁻ anion. The bands at 272, 256, 126 and 113 cm⁻¹ are assigned to Se₆ ring vibrations (Table 2). The symmetric Se–Se stretches (272 and 256 cm⁻¹) are at higher frequencies than those found in solid Se₆ (247 and 221 cm⁻¹),^{53,54} indicative of stronger Se–Se bonds in [Ag(Se₆)⁺]_∞ than found in solid Se₆, which possesses a large number of significant intermolecular Se₆...Se₆ contacts

Table 3 Summary of the ¹⁰⁹Ag and ¹⁹F chemical shifts and ¹J coupling constants in the solid state

Compound	δ _{iso} (¹⁰⁹ Ag)	δ _{iso} (¹⁹ F)	¹ J(¹⁹ F, X)/Hz ^a
AgF	-47 ^b	-318.2	—
AgF ₂	-189	-199.5	—
Ag[SbF ₆]	-221	-127.7	unresolved
Ag[AsF ₆]	-243	-67.6	975, 975
{1/∞[Ag(I ₂)] _∞ }[SbF ₆]	119	-75.4	2077
{1/∞[Ag(I ₂)] _∞ }[AsF ₆]	112	-110.6	977
{1/∞[Ag ₂ (Se ₆)] _∞ }[AsF ₆] ₂ , 4	-42	-53.4	970
	-220	-56.5	

^a X = As, Sb. ^b Our measurement of the ¹⁰⁹Ag NMR of solid AgF (-47 ppm) gives a different result compared to that of a previous study of a static sample (-110 (15) ppm) probably owing to the higher resolution of our MAS experiment.⁵⁹

reducing the effective Se–Se bonding within the ring, but similar to that observed for the Se₆ rings isolated in mordenite, Zeolite Y and SiO₂ matrix. The Se₆ Raman frequencies and intensities in [Ag(Se₆)⁺]_∞ are similar to those in [Se₆I]_∞ and PdCl₂(Se₆) (Fig. 9(c) and Table 3) except for an additional Se–Se stretch at 237 cm⁻¹ in PdCl₂(Se₆) (and PdBr₂(Se₆)) and 234 cm⁻¹ in {1/∞[Se₆I]_∞}[AsF₆].

This likely reflects the smaller Se–Se bond alternation and smaller variation of Se–Se bond lengths in $[\text{Ag}(\text{Se}_6)^+]_\infty$, compared to $\text{PdCl}_2(\text{Se}_6)$ and $[\text{Se}_6\text{I}^+]_\infty$.

The band observed at 171 cm^{-1} for **4** can be assigned to $\nu_s(\text{SeAgSe})$, which is consistent with the symmetric stretching vibrational frequency for $\nu_s(\text{SeISe})$ in $(\text{Se}_6\text{I}^+)_n$ (172 cm^{-1}) and $\nu_s(\text{SePdSe})$ in PdCl_2Se_6 (201 cm^{-1}). A similar intense Raman band was also observed for $\nu_s(\text{I–Ag–I})$ in $\{1/\infty[\text{Ag}(\text{I}_2)]_\infty\}[\text{SbF}_6]^{23}$ (99 cm^{-1}) and $\nu_s(\text{N–Ag–N})$ in $\text{Ag}(\text{NH}_3)_2^+$ (211 cm^{-1}).⁵⁵ Whether this band (171 cm^{-1}) is due to the Se–Ag2–Se stretch or the Se–Ag1–Se stretch or an overlap of both was investigated by quantum mechanical calculations (PBE0/TZVPP)⁵⁶ of the Se–Ag–Se-framework models **A**, **B** and **C** shown below Table 1: Calculated spectra of fragments **B** and **C** in Table 2 show bands at 188 cm^{-1} (low calculated scattering activity) and 161 cm^{-1} that are mainly composed of a Se–Ag2–Se stretching vibration with small admixtures of Se–Ag1–Se. Nevertheless the isolated $[\text{Ag}_2\text{Se}_6]^{2+}$ -model **A** also has a mode at 162 cm^{-1} , which consists of a combination of Se₆-stretching that also bears a significant amount of a Se–Ag1–Se vibration. However, the Raman-intense Se–Ag1–Se frequencies of **A** are calculated to occur significantly lower at around 100 cm^{-1} . Thus, the calculations of the model compounds suggest that the assignment of the experimental 171 cm^{-1} band is more likely a Se–Ag2–Se stretch.

¹⁰⁹Ag{¹⁹F} polarization transfer MAS NMR spectra of **4**, $\{1/\infty[\text{Ag}(\text{I}_2)]_\infty\}[\text{MF}_6]$ (M = As, Sb) and related fluorine-containing compounds

The ¹⁰⁹Ag NMR spectra were obtained with the recently introduced pulse technique PRESTO,⁵⁷ which is much less demanding to the NMR probe than ordinary ¹⁰⁹Ag cross polarization magic angle spinning (CP-MAS) experiments. This allowed the determination of the ¹⁰⁹Ag chemical shift values of the crystalline compounds in a relatively short time and to overcome the relative low receptivity (28% of that for natural abundance ¹³C) of ¹⁰⁹Ag.⁵⁸ AgF was the only silver-fluorine compound that was investigated prior to this work by static ¹⁰⁹Ag NMR experiments. Here we report the first examples (Table 3) of high-resolution ¹⁰⁹Ag signals by using PRESTO-III (from ¹⁹F to ¹⁰⁹Ag). In each structure of $\text{Ag}[\text{MF}_6]$ and $\{1/\infty[\text{Ag}(\text{I}_2)]_\infty\}[\text{MF}_6]$ (M = As, Sb), there is only a single crystallographically independent Ag atom, consistent with a single peak in the recorded ¹⁰⁹Ag NMR spectra. Due to anisotropic chemical shifts rotation side bands are observed in the ¹⁰⁹Ag spectra of $\{1/\infty[\text{Ag}(\text{I}_2)]_\infty\}[\text{MF}_6]$ (M = As, Sb) (ESI S5.2.2, ‡ for M =

Sb). The ¹⁰⁹Ag chemical shift in solid $\text{Ag}[\text{SbF}_6]$ is -221 ppm , representing a deshielding of 22 ppm with respect to that of solid $\text{Ag}[\text{AsF}_6]$ (-243 ppm), which is consistent with different chemical environment of Ag as in $\text{Ag}[\text{SbF}_6]$, Ag is surrounded by six F atoms (the shortest Ag–F distance is $2.505(2)\text{ \AA}$) while in $\text{Ag}[\text{AsF}_6]$, Ag is surrounded by ten F atoms (the shortest Ag–F distance is $2.220(5)\text{ \AA}$). A similar, but smaller deshielding (7 ppm), was observed for $\{1/\infty[\text{Ag}(\text{I}_2)]_\infty\}[\text{MF}_6]$ relative to the Sb homologue. The ¹⁰⁹Ag MAS NMR spectrum of **4** has two peaks (Fig. 6). The resonance at -220 ppm could be assigned to Ag(2) that is similar to that of $\text{Ag}[\text{SbF}_6]$ and has some Ag–F interactions and the peak at -42 ppm to Ag(1) with no fluorine contacts.

Gas phase, solution and solid state thermodynamics of **1** and **2A**

In order to understand the thermodynamics of the formation of the $[\text{Ag}_2\text{Se}_6]^{2+}$ cations several other species were calculated in addition to those shown above. Detailed information on their structure and energetics can be found in the ESI ‡ (S4.1/S4.2). The gas phase enthalpies and the Gibbs energies were calculated at the PBE0/tzvp level for the formation of possible reaction products. Gibbs free solvation energies, which have great influence on the thermochemistry, were taken into account using the conductor-like screening model COSMO with a dielectric constant of $\epsilon_r = 16.3^{52}$ (SO_2 , 298 K).⁶⁰ All results are summarized in Table 4.

The formation of $[\text{Ag}_2\text{Se}_6]^{2+}$ at 298.15 K in the gas phase is exothermic ($\Delta_r H = -120\text{ kJ mol}^{-1}$) and becomes more favourable with the addition of two SO_2 molecules ($\Delta_r H = -298\text{ kJ mol}^{-1}$) and about 100 kJ mol^{-1} more favourable still with addition of two further SO_2 molecules (less Coulomb repulsion by delocalisation of positive charge). Gibbs energies show the great influence of the loss of entropy for this reaction. The reaction of silver ions, selenium and SO_2 leading directly to $[(\text{OSO})\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})]^{2+}$ and $[(\text{OSO})_2\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})_2]^{2+}$ are exergonic with $\Delta_r G = -186\text{ kJ mol}^{-1}$ and -193 kJ mol^{-1} respectively. If solvation is taken into account the Gibbs energy remains exergonic with -185 kJ mol^{-1} **1**, and -125 kJ mol^{-1} for **2a**. However, it is much more appropriate to use the $\text{Ag}(\text{OSO})^+$ and $\text{Ag}(\text{OSO})_2^+$ cations as models in solution. The comparison of the Gibbs energies shows that in solution the coordination of Se_6 to form $[\text{Ag}_2\text{Se}_6]^{2+}$ is in preference to Ag– SO_2 coordination (about 50 kJ mol^{-1}). In solution the coordination of two SO_2 molecules (**1**) to the $[\text{Ag}_2\text{Se}_6]^{2+}$ unit is favoured by $\Delta_r G = -37\text{ kJ mol}^{-1}$; the coordination of four SO_2 endergonic

Fig. 6 ¹⁰⁹Ag{¹⁹F} MAS NMR spectrum of **4** obtained with the PRESTO-III sequence.

Table 4 Calculated thermodynamics for formation and decomposition reactions of $[(\text{OSO})\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})]^{2+}$ in **1**, $[(\text{OSO})_2\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})_2]^{2+}$ in **2a**, $[\text{Ag}_2\text{Se}_6]^{2+}$, Se_6^{2+} and Se_8^{2+} in the gas phase and SO_2 solution at 298 K. Values in kJ mol^{-1} (PBE0/TZVPP)

^a These reactions were calculated as follows: $\{\text{Se}_{6 \text{ or } 8} \rightarrow \text{Se}_{6 \text{ or } 8}^{2+} = \Sigma (1\text{st IE} + 2\text{nd IE})\} + \{2 \text{Ag}^+ \rightarrow 2 \text{Ag} (-2 \times \text{IE Ag})\}$. ^b Entropy contributions are approximately 0.

by +23 kJ mol^{-1} (**2a**). Nonetheless, complex **2a** is formed in the solid state, which is attributed to a gain in lattice enthalpy (see below).

The ⁷⁷Se NMR spectra of **2** at 298 and 233 K (three ⁷⁷Se unassigned resonances) suggest a dynamic system of coordination and dissociation of SO_2 and Se_6 to Ag^+ , which may be accompanied by selenium cation formation. This picture is completely supported by the calculated Gibbs energies in SO_2 solution in Table 4. Nevertheless, the pivotal question remaining is, why the synthesis of Se_6^{2+} was unsuccessful, while Se_8^{2+} and Se_{10}^{2+} were at least visible in the NMR spectra as intermediates. Two possible isomers of a hypothetical Se_6^{2+} were calculated (ESI† S5.5) with a relative enthalpy difference of 24 kJ mol^{-1} in favour of the boat conformer (*cf.* the known boat Te_6^{2+}).^{61,62} As expected, the oxidation $\Delta_r H(\text{g})$ and $\Delta_r G(\text{g})$ of Se_6 by two Ag^+ to form both isomers of Se_6^{2+} and elemental silver is highly unlikely in the gas phase. Also the oxidation of Se_8 to give the known¹² Se_8^{2+} dication is unfavourable in the gas phase. If solvation is considered the Gibbs reaction energy of the formation of the selenium cations remains endergonic. The description of open shell systems with COSMO is not advisable because it may be grossly misleading. Therefore the calculation was performed with the closed shell silver dimer. Nevertheless this system is purely hypothetical and far away from the true nature of the solvated system. At last a Born–Fajans–Haber-cycle starting from elemental selenium and solvated $\text{Ag}(\text{OSO})_2^+$ leading to solvated selenium cations and solid silver metal gives a more reliable picture. The formation of the solvated cations is estimated to be endergonic by 122 kJ mol^{-1} (Se_6^{2+}) to 147 kJ mol^{-1} (Se_6^{2+} chair). Nonetheless the ⁷⁷Se-NMR-spectrum gave evidence for the formation of Se_8^{2+} . Therefore Se_6^{2+} might indeed also be formed and could be one of the three unassigned signals.

This leads to the question to what extent the solid state influences the thermodynamics. An estimation of the lattice potential energies using the empirically derived formula refined

by Jenkins was carried out. For this Volume Based Approach the volume of the anions and cations were taken from the literature or otherwise were calculated with COSMO (Table deposited with ESI† S4.2.1). The reaction enthalpies leading to the solid products were assigned with Born–Fajans–Haber-cycles using the calculated gas phase enthalpies collected in Table 4 (Scheme 1). The sublimation enthalpy $\Delta_{\text{sub}}H$ from grey selenium leading to $\text{Se}_6(\text{g})$ is 138.6 kJ mol^{-1} ,⁶³ the lattice enthalpy $\Delta_{\text{latt}}H$ of $\text{Ag}[\text{Sb}(\text{OTeF}_5)_6]$ was calculated to be 366 kJ mol^{-1} and the value for $\Delta_{\text{vap}}H^{298 \text{ K}}(\text{SO}_2)^{52}$ is 23 kJ mol^{-1} . The lattice enthalpy of **1** was calculated as 1027 kJ mol^{-1} leading to the reaction enthalpy $\Delta_r H(\text{s})$ in Scheme 1 of -415 kJ mol^{-1} . The results for different possible products are summarized in Table 5.

Scheme 1 Born–Fajans–Haber cycle for the estimation of the solid state thermodynamics of the formation of **1** from grey selenium, $\text{Ag}[\text{Sb}(\text{OTeF}_5)_6]$ and SO_2 .

Using a related approach the solid state reaction enthalpies of several competing reactions were investigated (all cycles and auxiliary data are deposited in the ESI† S4.1 and S4.2). All results are collected in Table 5.

Since the $[\text{Al}(\text{OC}(\text{CF}_3)_3)_4]^-$ and $[\text{Sb}(\text{OTeF}_5)_6]^-$ anions are of comparable size (724 vs. 758 \AA^3), we expect similar behaviour

Table 5 Solid state reaction enthalpies $\Delta_r H$ (s) in kJ mol⁻¹

$6 \text{ Se}_{\text{grey(s)}} + 2 \text{ Ag}[\text{Sb}(\text{OTeF}_3)_6]_{\text{(s)}} + 2 \text{ SO}_{2(\text{l})} \rightarrow [(\text{OSO})\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})][\text{Sb}(\text{OTeF}_3)_6]_2_{\text{(s)}}$	-415
$6 \text{ Se}_{\text{grey(s)}} + 2 \text{ Ag}[\text{Sb}(\text{OTeF}_3)_6]_{\text{(s)}} + 4 \text{ SO}_{2(\text{l})} \rightarrow [(\text{OSO})_2\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})_2][\text{Sb}(\text{OTeF}_3)_6]_2_{\text{(s)}}$	-459
$6 \text{ Se}_{\text{grey(s)}} + 2 \text{ Ag}[\text{Sb}(\text{OTeF}_3)_6]_{\text{(s)}} \rightarrow [\text{Ag}_2\text{Se}_6][\text{Sb}(\text{OTeF}_3)_6]_2_{\text{(s)}}$	-291
$6 \text{ Se}_{\text{grey(s)}} + 2 \text{ Ag}[\text{Sb}(\text{OTeF}_3)_6]_{\text{(s)}} \rightarrow \text{Se}_6[\text{Sb}(\text{OTeF}_3)_6]_2_{\text{(s,chair)}} + 2 \text{ Ag}_{\text{(s)}}$	-214
$6 \text{ Se}_{\text{grey(s)}} + 2 \text{ Ag}[\text{Sb}(\text{OTeF}_3)_6]_{\text{(s)}} \rightarrow \text{Se}_6[\text{Sb}(\text{OTeF}_3)_6]_2_{\text{(s,boat)}} + 2 \text{ Ag}_{\text{(s)}}$	-238
$6 \text{ Se}_{\text{grey(s)}} + 2 \text{ Ag}[\text{Sb}(\text{OTeF}_3)_6]_{\text{(s)}} \rightarrow \text{Se}_3[\text{Sb}(\text{OTeF}_3)_6]_2_{\text{(s)}} + 2 \text{ Ag}_{\text{(s)}}$	-281

and did not additionally investigate the aluminate based reactions. The values for the reaction enthalpies $\Delta_r H$ (s) in Table 5 show that **1** is more than 100 kJ mol⁻¹, and **2a** an additional 40 kJ mol⁻¹ more favourable than all other suggested products (Se_6^{2+} , Se_8^{2+}). The influence of the entropy is neglected in this investigation, because it has only minor influence on the solid state estimations. This again shows that the formation of **1** and **2a** is induced by the high lattice potential energies of the respective dication salts $[(\text{OSO})\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})][\text{Sb}(\text{OTeF}_3)_6]_2$ and $[(\text{OSO})_2\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})_2][\text{Al}(\text{OC}(\text{CF}_3)_3)_4]_2$. The preference for the $[(\text{OSO})\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})]^{2+}$ cation in **1** and $[(\text{OSO})_2\text{Ag}(\text{Se}_6)\text{Ag}(\text{OSO})_2]^{2+}$ in **2a** may be explained by the reaction environment: **1** crystallized from an oily residue left open in the atmosphere of a glove box and thus SO_2 was a minimum factor. In agreement with the Gibbs energies collected in Table 4 in solution, the addition of the second SO_2 molecule is even slightly endergonic and thus under the experimental conditions the excess SO_2 did probably escape into the atmosphere of the glove box. By contrast, crystals of **2a** were obtained in the presence of SO_2 solvent and were mounted on the diffractometer at low temperatures (-50°C). Thus no possibility to escape the system was given and thus, in agreement with the solid state reaction enthalpy in Table 5, the SO_2 rich salt **2a** was formed.

Bonding considerations

All Ag–Se distances in **1**, **2a** and the $[\text{Ag}(\text{Se}_6)^+]_{\infty}$ stacks in **3** and **4** as well as in the calculated structures (Table 1 and Fig. 5) are in the same range (2.744–3.063 Å), but longer than the Ag2–Se–bonds linking the Se_6 rings in **4** (2.688(3) Å). The latter distance is similar to those in $(\text{AgI})_2\text{Se}_6$ (2.686(2) Å) and the average distances found for silver selenides,⁶⁴ e.g. 2.67(4) Å(ave) in $(\text{Ph}_4\text{P})\text{Ag}(\text{Se}_4)_n$. Also the calculated fragments **B** and **C** show this bond shortening for Ag2–Se. This stronger bond induces a Se–Se bond lengths alternation in Se_6 similar to that found in PdCl_2Se_6 via $4p^2 \rightarrow \sigma^*(\text{Se}–\text{Se})$ interactions and slight lengthening of the Ag1–Se1 distance relative to the Se2–Ag1 bond (see Fig. 7/Table 1).

The Wiberg Bond Indices (WBI) support this picture (Se–Se 1.07 vs. 0.93) as well as NBO analysis with a significant donation from the $\text{Se } 4p^2$ -LP to the neighbouring $\sigma^*(\text{Se}–\text{Se})$ orbital (S 4.3.2). All the Se–Se–Ag1 angles in **1–4** and the calculated structures are about 90° implying Se $4p^2$ electron pair donation in to the acceptor orbital of Ag^+ , driven by Ag–Se bond formation and positive charges delocalization from Ag^+ to Se_6 (cf. IE: $\text{Ag}_{(\text{g})} = 731$, $\text{Se}_{(\text{g})} = 857$ kJ mol⁻¹). Charge distribution to the selenium ring is found also with NPA and PABOON. While in the first the natural charges support clearly a charge separation $\text{Ag}^+–\text{Se}_6$ (Ag: 0.76, Se: 0.03/0.04), the PABOON multicentre charge is more

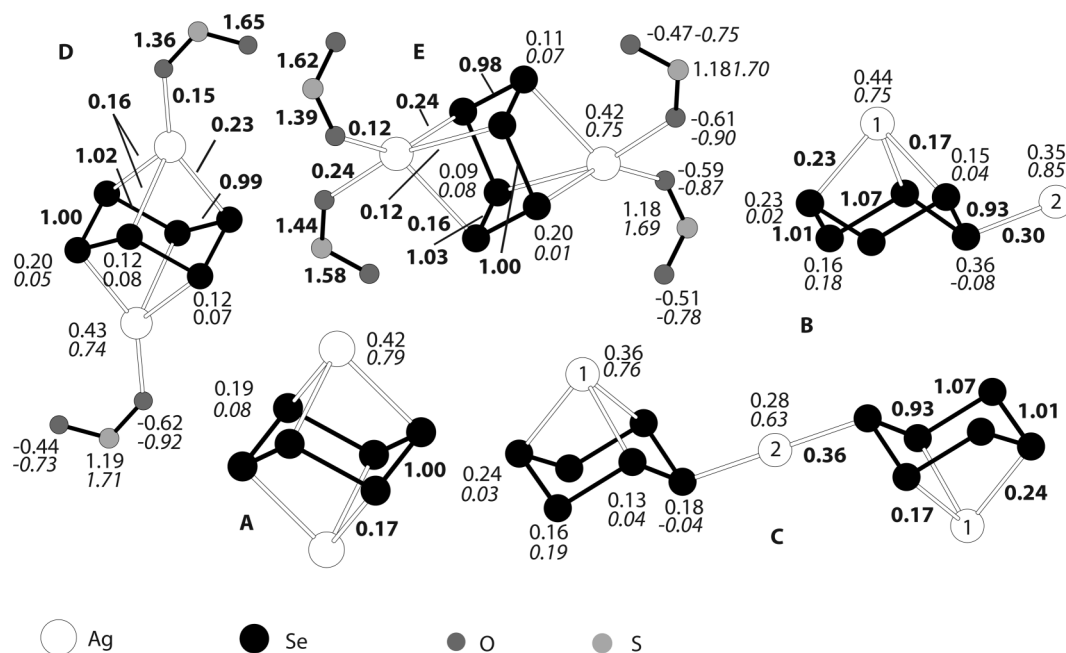

Fig. 7 Calculated structures A–E. Regular: Multicentre corrected PABOON (Population Analysis Based On Occupation Numbers) atom charges; *Italics*: NPA (Natural Population Analysis) natural charges; **Bold**: Wiberg Bond Indices (WBI).

evenly distributed over the atoms (Ag: 0.36, Se: 0.13–0.24). The observation of secondary Se–F contacts between the selenium atoms of the six membered rings and the fluorine atoms of the anions in **1** to **4** (See Table 1) gives evidence for relatively higher positive charge distribution to the selenium rings as suggested by the PABOON analysis. The silver atom Ag2 involved in the shortened Ag2–Se bond in **B** and **C** bears a more populated 5 s silver orbital (Natural Electron Configuration 5s(0.44) Ag2 vs. 5s(0.24) Ag1) and there are lower charges on Ag2 (0.28 PABOON/0.63 NPA) vs. Ag1 (0.36/0.76) (see Fig. 7).

The observed Se–Se bond alternation in **4** was verified by the calculated structures as well as population analyses (see Fig. 7). Due to the stronger Se1–Ag2 contacts (2.688(2) Å), the Se1–Ag1 (2.941(3) Å) and Se1–Se2 (2.362(2) Å) distances are longer than those in **1–3**. Also the higher WBI of 0.36 for the Se–Ag2 bond vs. 0.17 and 0.23 for the Se–Ag1 bonds reflects the influence of the strong Se–Ag2 contact. For Se2 directly neighbouring two silver atoms a special situation arises: it acts as a 4p² electron pair donor to both Ag1 and Ag2 with a deviation of about 30° from the Se2–Ag2–Se2 angle (see Fig. 1d). If hybridization of 4 s and 4p orbitals is considered two lone pairs become available for donation with a much better overlap with the silver acceptor orbitals. The NBO analysis underlines this possibility; some core electron density from selenium (4 s) is donated to the Ag2 5s⁰ orbital (S 4.3.2₊). A quantitative influence on Ag1 could only be given by a fragment with two additional Ag1 atoms, the calculation of which with a +5 charge is not sensible. Overall, the population analyses (particularly PABOON) and the Se–F contacts in the crystal structures suggest 4p² → σ* charge delocalization over the entire 1D and 2D network.

Conclusion

Attempts to prepare Se₆[A]₂ ([A][−] = [Sb(OTeF₅)₆][−], [Al(OC(CF₃)₃)₄][−]) containing the hitherto unknown Se₆²⁺ dication, by the reaction of elemental selenium and Ag[Sb(OTeF₅)₆] and bromine led to the formation of [(OSO)Ag(Se₆)Ag(OSO)][Sb(OTeF₅)₆]₂ **1**. Our attempts to prepare **1** directly from selenium and Ag[Sb(OTeF₅)₆] were not successful, but the related compound [(OSO)₂Ag(Se₆)Ag(OSO)₂][Al(OC(CF₃)₃)₄]₂ **2a** was prepared from selenium and Ag[Al(OC(CF₃)₃)₄]. Reaction of Ag[MF₆] (M=As,Sb) with elemental selenium lead to crystals of **3** and **4** containing unsolvated polymeric [Ag(Se₆)⁺]_∞ stacks that are additionally –Ag–SeSe₄SeAg– cross linked in **4**. The latter is best prepared by the reaction of Se₄[AsF₆]₂, silver metal and elemental selenium in the correct stoichiometric ratio according to equation 6. The PRESTO III sequence enabled us to obtain well resolved ¹⁰⁹Ag MAS NMR spectra of **3**, **4**, and the silver-fluorine containing compounds, AgF, AgF₂, AgMF₆ and {1/∞[Ag(I₂)_∞]}[MF₆] (M = As, Sb). These are the first examples of ¹⁰⁹Ag MAS NMR spectra of fluorine containing compounds obtained in reasonable time and resolution scales.

The coordination polymers **3** and **4** may possess interesting physical properties e.g. electrical conductivity, which await future investigations.

It appears very likely that the aggregation behaviour of the Ag⁺–Se₆ system is directly related to ion size: In compounds **1** and **2a** with very large anions (*V*_{anion} = 0.724⁶⁵ and 0.758⁶⁶ nm³)

the formation of Ag–Se₆ polymeric chains is not possible due to the smaller [Ag₂Se₆]²⁺ building blocks. The coordination sphere of Ag⁺ is saturated by Se₆ and SO₂. When the smaller [Ag₂(SbF₆)₃][−] and [AsF₆][−] anions are involved (*V*_{ion} ≈ 0.375 and 0.110 nm³),⁶⁷ the reduced space requirement of the smaller anion allows for a polymeric packing. Thus, the soft Ag⁺ acid seeks a preferred entirely HSAB-soft environment which is constructed from six Se atoms, and not the mixed hard-soft Se₃O_xF_y arrangements in **1** and **2a**. Finally, the additional cross-linking in **4** is developed by the formation of again smaller [Ag₂(SbF₆)₃][−] anion. This work suggests that the structurally hitherto uncharacterised [Ag(Te_x)⁺ cations (anions [MF₆][−], M = As, Sb) are likely also polymeric.⁶⁸

In all compounds, the polymeric spirals in grey selenium are converted into the metastable molecular cyclo Se₆ form. This new class of [Ag(Se₆)]⁺ salts together with salts containing [Ag(S₈)_n]⁺ (*n* = 1, 2), [Ag(P₄)_n]⁺ (*n* = 1, 2) and [Ag(I₂)_n]⁺, imply the emergences of a novel coordination chemistry of metal cation - electronegative element molecules. It is possible that elusive cations such as [M(N₂)⁺ (M = Na, K),⁶⁹ [Au(X₂)⁺ (X = Cl, Br),^{70,71} [Li(P₄)⁺,⁷² [Ag(C₆₀)⁺,⁷³ and related [M(NO)_x]⁺ (M = Ag, Cu; *x* = 1, 2),^{74–77} which have been detected in gas phase, may one day be isolated on the preparative scale with suitable weakly coordinating anions.

The Se₆ rings in all the silver complexes are all positively charged and partially oxidised. As possible intermediates they may provide a safer route to homopolyatomic cations. Previously, those were synthesized by reactions of strong oxidation agents, e.g. MF₅ (M = As, Sb) and S₂O₆F₂, with the corresponding element or *via* solid state methods. However the experimental findings and an analysis of the energetics of the system showed that in the solid state the Ag–Se₆ complexes were favoured over the pure selenium cations. The neutral Se₆^{78–80} may be displaceable from these salts on addition of a stronger base, assuming that Se₆ is not converted to thermodynamically stable Se₈ or grey Se_∞. This was observed in preliminary experiments by addition of acetonitrile as a base to [Ag(Se₆)]-containing solutions that will be reported elsewhere.

Experimental section

General techniques

General techniques and methods have been described elsewhere.⁸¹ Reactions were carried in a two bulb (Pyrex, 25 ml), two valve (Teflon in glass, o.d. 0.5 cm) vessel, or a two tube (Pyrex, o.d. 1.5 cm, length 10 cm), two valve (Teflon in glass, o.d. 0.8 cm) vessel, incorporating a medium frit and a Teflon coated stirring bar magnet. All vessels were carefully flame dried *in vacuo* prior to use. Moisture-sensitive materials and all solid products were manipulated in a Vacuum Atmospheres Dri-Lab equipped with a Dri train (HE-493) and an internal circulating drying unit containing one kg of 3 Å molecular sieves or in Argon filled Glove Boxes (M. BRAUN) with O₂ and H₂O content below 1 ppm. Chemical analyses were performed by Galbraith Laboratories, Inc. and at the Institut für Anorganische Chemie, Friedrich Wilhelm Universität (Bonn). FT-IR spectra of Nujol mulls between KBr disks were recorded on a Thermo Nicolet FT IR 470 spectrometer (32 scans; resolution, 2.0 cm^{−1}). FT-Raman spectra were recorded on a Bruker IFS66 FT-IR spectrometer equipped with a Bruker FRA106 FT-Raman accessory using a Nd: YAG laser (emission wavelength, 1064 nm; maximum laser power, 3009 mW). Samples

were sealed in melting point capillaries, and data were collected in the backscattering mode (180° excitation). Raman spectra of **2a** were recorded using a Bruker Vertex 70 equipped with a RAM II module using a 1064 nm Nd:YAG laser source in 180° backscattering mode.

Chemicals

Silver powder (99.995, Alfa Aesar), Grey selenium powder (99%, BDH Chemicals and 99.7% Aldrich (**2a/b**) and selenium pellets (99.999+%, ~ 2 mm, Aldrich) were used without further purification. Ag[SbF₆] (SynQuest. Labs. Inc.) was dissolved in liquid SO₂ and the insoluble portion removed by filtration. Ag[AsF₆],⁸² Se₄[AsF₆]₂⁸¹ and Ag[Al(OC(CF₃)₃)₄]⁸³ were prepared as described.

The purity of AgMF₆ (M = As, Sb) was confirmed by FT-Raman spectroscopy. AgSbF₆ (Acros), AgF (Merck), and AgF₂ (Riedel, >98%) were used for ¹⁰⁹Ag solid state NMR measurements without further purification. (AgI₂)MF₆ (M = As, Sb) was prepared according to literature procedures.²³ SO₂ (BOC Canada Ltd.) and SO₂ClF (Matheson) were distilled onto and stored over CaH₂ or molecular sieves (4 Å) respectively at least 24 h prior to use. CH₂Cl₂ (99.5% min., Anachemia Science) was stirred over P₂O₅ for two days and then distilled onto and stored over CaH₂ at least 24 h prior to use. F-114 (Cl₂FC-CFCl₂, Matheson) was distilled onto and stored over molecular sieves 3 Å at least 48 h prior to use. Teflic acid, F₃TeOH, was prepared from Oleum, NaF and Te(OH)₆ by a modification of the literature method.⁸⁴

Preparation of AgOTeF₅

Preparation of AgOTeF₅ followed the published method (AgF + HOTeF₅ in CH₂Cl₂).⁸⁵ However, in our hands it was impossible to remove all traces of the solvent CH₂Cl₂ by subjecting the purified AgOTeF₅ over night to a dynamic vacuum. This was shown by the ¹H-NMR spectrum of a sample of AgOTeF₅ dissolved in SO₂, which showed one line at δ¹H = 5.23 ppm [cf. δ¹H(CH₂Cl₂) = 5.30 ppm in CDCl₃].⁸⁶ The ¹⁹F-NMR shifts of the AB₄ spin system of AgOTeF₅ in SO₂ were not reported previously and are δ¹⁹F = -27.7 ppm (1F, quint., F_A) and -38.5 ppm (4F, d, F_B) with ²J(F_A-¹⁹F_B) = 180.0 Hz.

Preparation of Ag[Sb(OTeF₅)₆]

In our hands we were unable to prepare Ag[Sb(OTeF₅)₆] free of CH₂Cl₂ by the published procedures.⁴¹ However we were able to markedly reduce the impurity by the use of F-114/SO₂ as a solvent, and the resulting Ag[Sb(OTeF₅)₆] was used in our reactions below. A full account is given in the supplementary material. ‡

Solution NMR

Solution NMR spectra were obtained of samples in 10 mm (o.d.) thick walled NMR tubes fitted by a J. Young valve. They were recorded between -70 °C and r.t. on a variable temperature, multinuclear Varian Associates Unity 400 spectrometer and were referenced against external TMS (CDCl₃, ¹H), CDCl₃ (neat, ¹³C), FCCl₃ (SO₂, ¹⁹F), Me₂Se (neat, ⁷⁷Se), and SbF₆⁻ (aqueous, ¹²¹Sb) as a standard (r.t.). The solution NMR spectra of **2a** were recorded on a Bruker Avance II+ 400 WB spectrometer at 25 °C and -40 °C in 5 mm NMR tubes fitted by a J. Young valve.

Solid-state NMR

The ¹⁰⁹Ag and ¹⁹F solid state NMR experiments were carried out on a Varian Infinity spectrometer equipped with a commercial 4 mm MAS NMR triple-resonance probe utilizing a low-gamma extension box for the ¹⁰⁹Ag channel. The magnetic field strength was 9.4 T corresponding to a ¹⁰⁹Ag and ¹⁹F resonance frequency of 18.68 and 377.81 MHz, respectively. The ¹⁰⁹Ag MAS NMR spectra were acquired using the PRESTO-III experiment. Those are non-quantitative with respect to the ratio of peak intensities. The PRESTO-III pulse sequence is described in detail in reference.⁵⁷ The spectra shown have been acquired in typically 2–6 h with a repetition delay of 5 s at room temperature and continuous wave ¹⁹F decoupling. The nutation frequency for the hard pulses on the ¹⁰⁹Ag channel was 31 kHz. At 12 kHz spinning frequency the ¹⁹F nutation frequency used for the R18₂⁵ amounts to 54 kHz. The transfer times τ₁ and τ₂ were optimised on the sample and typically set to values around 5.333 ms. The ¹⁰⁹Ag chemical shifts refer to a solution of 9 M AgNO₃ + 0.25 M Fe(NO₃)₃ in H₂O and the ¹⁹F chemical shifts to CFCl₃. All experiments were carried out at room temperature.

Reaction of Ag[Sb(OTeF₅)₆] with grey Se leading to dissolved Se₁₀[Sb(OTeF₅)₆]₂

Grey Se powder (0.189 g, 2.394 mmol) and 1.048 g beige Ag[Sb(OTeF₅)₆] (0.631 mmol) were carefully ground together for about five minutes and the resulting light grey material loaded into a two-bulb frit-plate vessel equipped with a specially designed NMR-outlet to allow the preparation of NMR samples.⁶⁵ The mixture was ultrasonicated at ca. 30 °C for 3–4 hs giving an intensely brownish/black product to which 11.86 g of SO₂ was added giving a deep brown solution which was filtered and a portion was poured into a 10 mm (o.d.) NMR tube (4.64 g solution). The ⁷⁷Se-NMR spectra of this sample (r.t., -30 °C and -70 °C) showed lines at δ⁷⁷Se = 1103 and 766 ppm as well as those attributable to Se₈²⁺ (only -70 °C) characteristic of Se₁₀²⁺ [reversible low temp. disproportionation to Se₈²⁺ and Se₁₇²⁺]. 0.58 g of a dark brown solid were recovered which had a very poor FT-Raman spectrum (strong fluorescence). 24 h later the FT-Raman showed small amounts of elemental selenium and an isolated weak C–H stretch at 2860 cm⁻¹. A similar decomposition behavior of the Se₁₀²⁺ cation was reported.³⁹ Similar experiments reacting Se and Ag[Sb(OTeF₅)₆] in SO₂ solution designed to prepare [Se_x][Sb(OTeF₅)₆]₂ (x = 6, 8) led to a mixture of Se₈²⁺ and Se₁₀²⁺ (⁷⁷Se NMR at -70 °C, SO₂ as solvent). Details are given in the supplementary material (S6). ‡

Reaction leading to single crystals of **1**

41.33 g of F-114 was condensed onto grey Se (0.180 g, 2.280 mmol), Se₂Br₂ [prepared by heating Se (0.159 g, 2.016 mmol) and Br₂ (0.167 g, 1.042 mmol) for 1–2 min to ca. 100 °C] and solid Ag[Sb(OTeF₅)₆] (2.510 g, 1.511 mmol). The resulting suspension was stirred over night. It appeared that no reaction had occurred, therefore SO₂ (1.45 g) was added. On warming to 5 °C, the solution turned dark green (colour of Se₈²⁺), within 5 to 10 mins but after 15 min only a yellow-beige precipitate over a light yellow solution remained. Stirring over night at +5 °C, filtration and removal of the solvent resulted in the separation of a few drops of a yellow-orange

oil from the solution, which was washed back into the reaction bulb and the volatiles removed *in vacuo* (1.5 h at HV). 17.92 g of SO₂ were condensed onto the yellow-beige solid material, giving a fine precipitate (colourless, AgCl?) and a clear yellow-orange coloured solution. Filtering this solution into the second bulb (at +5 °C) and cooling the first bulb to 0 °C afforded needle like yellow crystals. These were isolated by pouring the supernatant solution back into the reaction bulb and removing all the volatiles *in vacuo*, leaving a large amount of a yellow-orange oil. This vessel was cut open in the dry box to isolate the crystals (0.737 g) [This material showed strong fluorescence in the FT-Raman spectrum; no ⁷⁷Se NMR spectrum at r.t. and -70°, 0.32 g in SO₂, 3000 scans]. Upon addition of acetonitrile to these SO₂ solutions the immediate precipitation of a red substance was observed (red selenium?). Large yellow-orange cube like crystals grew from the remaining oil in the second bulb with its valve closed in the dry box after 3 months. An X-ray crystal structure determination of one of the multitude of very similar appearing crystals showed it to be **1**.

Preparation of single crystals **2a** and bulk **2b**

Liquid SO₂ (20 ml) was condensed onto a mixture of grey selenium (0.88 g, 11.14 mmol) and pale yellow Ag[Al(OC(CF₃)₃)₄] (2.00 g, 1.91 mmol) (molar ratio 6 : 1) in a two bulbed Schlenk vessel with Young (J. Young, London) valves with a G4 frit in between. The reaction mixture can either be stirred for several days or sonicated for 6 h until the reaction mixture turns yellow-orange. The reaction progress can be monitored by colour changes. First the mixture turns green (indicating possible selenium cations), later on orange (formation of the complex). The mixture was filtered into the second bulb, giving a clear solution; remaining greyish residues were confirmed to be grey selenium by powder diffraction (ESI S9‡). The solution was concentrated until an orange oil remained and crystallized using the published “oil technique”.⁸⁷ **2a** crystallised at 2 °C within two days yielding orange crystals sensitive towards light and atmosphere. Upon removal of the remaining solvent 1.65 g (theory for 100% yield based on eqn (2): 2.44 g) of an orange powder was obtained **2b**. No peaks attributable to (coordinated) SO₂ were visible in the IR of the orange powder: IR(ZnSe-ATR): 1355(w), 1299(sh), 1240 (s), 1211 (s), 1176 (s), 1128 (sh), 968 (vs), 862 (w), 831 (w), 796 (w), 725 (s) cm⁻¹. NMR(SO₂, 298 K): ¹⁹F ([Al(OC(CF₃)₃)₄]⁻ -75.3 ppm), ²⁷Al ([Al(OC(CF₃)₃)₄]⁻ 34.6 ppm), ⁷⁷Se (unassigned, see ESI S9‡).

Preparation of single crystals of **3** and **4**

About 30 ml SO₂ was condensed onto a mixture of Ag[MF₆] (M = Sb (**3**) 1.0 g, As (**4**) 4.35 g) and selenium powder (M = Sb 0.044 g, M = As 0.1 g) in one tube of a standard two bulb, two-valve vessel (H vessel)⁸⁸ fitted with a medium porosity frit and a magnetic stirring bar. On warming to r.t. orange (**3**) and yellow (**4**) solutions were formed and immediately filtered without washing. Small amounts of orange (**3**) or yellow crystals were given after a few minutes at r.t.. The H-vessel was cooled to -78 °C and one valve was opened under argon. The crystals were picked out of the solution by using a miniature nickel spoon. One crystal suitable for X-ray crystal structure analysis was chosen and quickly placed in the fluorinated oil cooled in a stream of liquid nitrogen and

examined under the microscope. The crystal was mounted in the end of a glass needle and placed into liquid nitrogen, and then into the cold N₂ stream of the diffractometer. By this method small quantities of crystals of **3** and **4** were isolated.

Reactions leading to bulk **4**, method 1: reactions of Ag[AsF₆] with Se pellets

Liquid SO₂ (15.665 g) was condensed onto AgAsF₆ (1.315 g, 4.431 mmol) and Se pellets (0.164 g, 2.077 mmol) in one bulb of a two-bulb vessel. A bright yellow solution above the unreacted Se pellets was observed after stirring for two hours. The size of the Se pellets reduced after stirring for two days with formation of a bright yellow solid under a yellow solution. The insoluble (Se and yellow product) and soluble materials were separated by repeated washings (5 times) across the frit. The solvent was removed giving 0.222 g (calc. 0.245 g, based on equation 5 above) of a yellow insoluble product separately manually from 0.055 g unreacted Se pellets and 1.131 g unreacted AgAsF₆ (calc. 1.265 g). Thus the ratio of Se : Ag[AsF₆] reacted was about 3 : 1. Elemental analysis calcd (%): Se 44.39, Ag 20.21, As 14.04; found: Se 43.4, Ag 20.6, As 14.6). In a related reaction of Se pellets (1.965 g, 24.886 mmol) reacted with Ag[AsF₆] (0.934 g, 3.147 mmol) (molar ratio: Se/AgAsF₆ = 8 : 1) for 24 days in which time all Ag[AsF₆] was consumed giving 1.210 g (cal. 1.214 g based on all reacted Ag[AsF₆]) and 1.689 g (calc. 1.679 g) yellow product. The ratio of reacted Se: AgAsF₆ was 3 : 1. Elemental analysis calcd (%): Se 44.39, Ag 20.21, F 21.36, As 14.04; Found: Se 44.47, Ag 19.85, F 21.46, As 14.57. The frequencies of FT-IR and FT-Raman for the yellow product from these two reactions are included in ESI Table 1.2, and its FT-Raman spectrum is shown in ESI Figure S3.‡ Other reactions of Ag[MF₆] (M = As, Sb) with Se (powder and pellets) together with these two reactions are summarized in Table S1.1.‡ Corresponding reaction weights, FT-IR data, FT-Raman data and X-ray powder fraction patterns were given in the supplementary material (ESI S1.3–S1.7‡). The X-ray powder pattern calculated from the single crystal data of **4** was in good agreement with the experimental X-ray powder data (ESI 1.8‡) and the ¹⁰⁹Ag MAS NMR gave two ¹⁰⁹Ag resonances in agreement with the structure of **4** (Table 3).

Method 2: reaction of Se₄[AsF₆]₂ with the Ag metal and the Se powder (mole ratio: 1 : 2 : 2)

Liquid SO₂ (about 10 g) was condensed onto a mixture of yellow-green Se₄[AsF₆]₂ (0.693 g, 0.999 mmol), black Se powder (0.152 g, 1.925 mmol) and silver (0.213 g, 1.975 mmol) in one bulb of a two bulb vessel. The reaction was stirred at room temperature for 15 days. The yellow solution was filtered and the insoluble yellow material was washed five times with SO₂. Removal of SO₂ gave a yellow insoluble product (1.003 g, calcd. 1.058 g based on equation 5 above). Elemental analysis calcd (%): Se 44.39, Ag 20.21, As 14.04; found: Se 43.0, Ag 21.4, As 14.3. The Raman spectrum and X-ray powder diffraction pattern (ESI S1.8‡) of the yellow insoluble product were identical to that from method 1.

X-ray crystal structure determinations

1: Crystals suitable for X-ray crystal structure determination were examined in the dry box by an externally mounted stereomicroscope (Leitz, magnification 6,18 and 40×) of long focal length.

Selected crystals were placed in rigorously dried capillary tubes and sealed under an atmosphere of dry nitrogen as previously described.⁸⁹ Crystals were mounted on a Siemens P4 diffractometer equipped with a SMART CCD detector. Frames were collected at 213 ± 1 K with an exposure time of 10 s and a scan range of 0.31° per frame. Data were corrected for Lorentz, polarization and absorption effects. The structure was solved by direct methods and refined by full matrix least squares refinement on F². All atoms were refined anisotropically. Structure solution and refinement was performed using the Siemens SHELXTL-Plus software package.⁹⁰

2a: Crystals were selected and prepared at 253 K in Perfluoroetheroil (ABCR), then mounted with a CRYOLOOP (Hampton Research) on a Rigaku R-Axis Spider diffractometer equipped with a Curved Image Plate detector. The frames were collected using Mo-K α -radiation (0.71073 Å) at *T* = 110(2) K (Oxford Cryostream 700) with an exposure time of 6 min (2 θ limited to 60°). Cell refinement, data reduction, Lorentz, polarization and empirical absorption correction as well as integration were carried out with the CRYSTALCLEAR⁹¹ software utilizing the FSPROCESS⁹² routine.

The structure was solved with the Patterson method (SHELXS97⁹³), and then refined stepwise by full matrix least squares refinement on F² with SHELXL97.⁹³ The data was limited using SHEL 999 0.875. The disorder in the anion for both -CF₃ and C(CF₃)₃-groups was refined anisotropically for the major site occupation and isotropically for the minor site occupation. The minor occupied disordered CF₃-groups were restrained using the SAME command, major occupied groups using the SADI command. N.P.D atoms were made isotropically using the ISOR command.

3 and 4: Crystals were mounted on a Bruker AXS P4 diffractometer with SMART 1000 detector, frames were collected at 173 ± 1 K. Data were corrected for Lorentz, polarization and absorption effects.

All relevant data referring to crystallography, data collection and refinement compiled in Table 6. Further details on the crystal structure determinations are deposited at the Fachinformationzentrum, Karlsruhe, Germany and may be requested by quoting

the depositing number CSD-418699 (**1**), 418700 (**3**), and 418701 (**4**). The structure of **2a** is deposited at the Cambridge Crystal Data Centre (CCDC) and may be requested by quoting the depositing number CCDC-814799. The graphical representations were prepared with DIAMOND.⁹⁴

Computational details

All structures were investigated at the DFT BP86⁹⁵/def-SV(P)^{96,97} and hybrid-DFT PBE0⁹⁸⁻¹⁰⁰/def2-TZVPP¹⁰¹ levels with a 28 electron ECP on silver.¹⁰² The calculations were carried out with the TURBOMOLE¹⁰³ V6.0 program package assuming the highest possible point group for each compound. Each optimised structure proved to be a minimum utilizing the AOFORCE module. If not otherwise stated no imaginary frequencies were found. Additional calculations were performed at the MP2/def2-TZVPP level with the resolution-of-the-identity and frozen core approximation.^{104,105} For the numerical calculation of vibrational frequencies the module NUMFORCE was used. Polarization tensors and their projection to the normal vibrational modes were calculated either by the module RAMAN or with both EGRAD and INTENSE. Enthalpies are calculated for 0 K or corrected to 298.15 K using the FreeH module with scaling factors (0.9833 for BP86/SV(P) and 0.97¹⁰⁶ for PBE0/def2-TZVPP). To take solvent effects into account single point calculations on the optimised geometries were performed using the COSMO model with ϵ_r = 16.3⁵² (SO₂, *T* = 298 K). Population Analysis Based On Occupation Numbers^{107,108} was accomplished. Full NBO analysis has been carried out as a single point calculation using PBE0/def2-TZVPP with GAUSSIAN03 (Rev. E.01).¹⁰⁹

- The $\Delta G^{\circ}_{\text{soln}}$ value calculated with COSMO is not the transfer from the ideal gas (1 atm) to 1 molar solution, so that the chemical potential difference $\Delta G^{\circ}_{\text{soln}} \rightarrow \Delta G^{\circ}_{\text{soln}}$ of 7.93 kJ mol^{-1} has to be added.
