#### Abstract

New pyrazolyl-diamine ligands with acridine derivatives at the 4-position of the pyrazolyl ring were synthesized and characterized ( $\mathbf{L} 1$ and $\mathbf{L 2}$ ). Coordination towards the $f a c-\left[\mathrm{M}(\mathrm{CO})_{3}\right]^{+}\left(\mathrm{M}=\mathrm{Re},{ }^{99 \mathrm{~m}} \mathrm{Tc}\right)$ led to complexes $f a c-\left[\mathbf{M}(\mathrm{CO})_{3}\left(\kappa^{3}-\mathrm{L}\right)\right](\mathbf{L}=\mathbf{L} \mathbf{1}: \mathbf{M}=\mathbf{R e} \mathbf{1}, \mathbf{T c} \mathbf{1} ; \mathbf{L}=\mathbf{L} \mathbf{2}: \mathbf{M}=\mathbf{R e} \mathbf{2}, \mathbf{T c} 2)$. The interaction of the novel pyrazolyl-diamine ligands ( $\mathbf{L} \mathbf{1}$ and $\mathbf{L 2}$ ) and rhenium(I) complexes ( $\mathbf{R e} \mathbf{1}$ and $\mathbf{R e} 2$ ) with calf thymus DNA (CT-DNA) was investigated by a variety of techniques, namely UV-visible, fluorescence spectroscopy and circular and linear dichroism. Compounds L1 and Re1 have moderate affinity to CT-DNA and bind to DNA by intercalation, while $\mathbf{L 2}$ and $\mathbf{R e} \mathbf{2}$ have a poor affinity for CT-DNA. Moreover, LD measurements showed that $\mathbf{L 1}$ and Re1 act as perfect intercalators. By confocal fluorescence microscopy we found that $\mathbf{L 1}$ and Re1 internalize and localize in the nucleus of B16F1 murine melanoma cells. The congener Tc1 complex also targets the cell nucleus exhibiting a time-dependent cellular uptake and a fast and high nuclear internalization ( $67.2 \%$ of activity after 30 min ). Plasmid DNA studies have shown that Tc1 converts supercoiled (sc) puc19 DNA to the open circular (oc) form.

## Introduction

Treatment of cancer still remains a great challenge for modern medicine, in particular the eradication of disseminated tumor cells and small metastases which cannot be treated efficiently with external radiation therapy or surgery. More recently, radionuclide therapy started to be envisaged as an alternative and powerful modality for the treatment of disseminated malignant diseases. ${ }^{1}$ So far, clinical radionuclide therapy relies on the use of $\beta^{-}$emitter (e.g. ${ }^{131} \mathrm{I},{ }^{90} \mathrm{Y}$ ) radiopharmaceuticals which are mainly applied for bone pain palliation and for treatment of neuroendocrine or hematological tumors. ${ }^{2}$ However, $\beta^{-}$emitters are not the best suited radionuclides to eliminate disseminated cells or small metastases, since most of the energy of $\beta^{-}$particles is absorbed by the surroundings and not by the target neoplastic cells which accumulate the radiopharmaceutical. For such type of application, $\alpha$ - and Auger electron emitters can be considered a more adequate choice than traditional $\beta^{-}$emitters, but the studies

[^0]with these radionuclides remain mostly pre-clinical. Nevertheless, Auger radiation therapy appears to be a new possible therapeutic pathway with in vitro experimental results already demonstrated for ${ }^{125} \mathrm{I},{ }^{111} \mathrm{In}$ and ${ }^{99 \mathrm{~m}} \mathrm{Tc}$. ${ }^{3-8}$
${ }^{99 \mathrm{~m}} \mathrm{Tc}$, the most used $\gamma$-emitter in SPECT (single photon emission computed tomography) imaging, emits also 4 Auger electrons per decay. These low energy electrons provide a high linear energy transfer (high LET) in association with a short tissue penetration, being therefore optimal for treatment of individual cancer cells. However, such application requires a selective accumulation of the radionuclide into individual tumor cells, namely in the nucleus, being highly toxic only when the Auger emitter is tightly bound to DNA. ${ }^{1}$ To ensure the close proximity of the emitting radionuclide to the DNA double helix and a prolonged retention time in the cell it is imperative to design multifunctional compounds bearing a DNA-binding unit. ${ }^{3,9}$ For ${ }^{99 \mathrm{~m}} \mathrm{Tc}$, Alberto et al. pioneered the study of such type of compounds and demonstrated in vitro that the Auger electrons emitted by ${ }^{99 m} \mathrm{Tc}$ strongly affect the structure of plasmid DNA with induction of double strand breaks. ${ }^{8}$ In our research group, we have also studied and evaluated $\operatorname{Re}(\mathrm{I}) /^{99 \mathrm{~m}} \mathrm{Tc}(\mathrm{I})$ tricarbonyl complexes anchored by pyrazolyl-diamine chelators and bearing anthracenyl groups for DNA binding. ${ }^{10-12}$ Our findings were encouraging since some of the anthracenyl-containing ${ }^{99 \mathrm{~m}} \mathrm{Tc}(\mathrm{I})$ tricarbonyl complexes rapidly entered the cells, accumulated inside the nucleus and exhibited a strong radiotoxic effect in murine melanoma cells with an apoptotic cellular outcome. However, the evaluated complexes only presented a moderate affinity to DNA and did not behave as perfect intercalators. Moreover, the anthracene chromophore did not display the best emission properties to allow the followup of the cellular trafficking of the Re congeners by fluorescence microscopy. To get a deeper insight into the relevance of pyrazolyl-diamine ${ }^{99 m} \mathrm{Tc}(\mathrm{I})$ tricarbonyl complexes in the design of

i) DMF, DIPEA, r.t., 5 days

Scheme 1 Synthesis of chelators L1 and L2.
site-directed radiopharmaceuticals for Auger therapy we decided to explore their functionalization with acridine derivatives which are another family of known DNA-binding molecules. By exploring acridine derivatives, we intended to obtain organometallic complexes with a higher DNA-binding affinity and with a better ability to intercalate into the double helix compared with the complexes bearing anthracenyl groups previously evaluated. ${ }^{10-12}$ In addition, acridine derivatives are polyaromatic fluorescent planar molecules considered as standard compounds for nuclear staining due to their strong emission properties. Therefore, the use of such chromophores should also allow an easier visualization of the cellular trafficking of the compounds by confocal fluorescence microscopy.

Herein, we report on the synthesis and characterization of new multifunctional pyrazolyl-diamine ligands bearing DNAbinding motifs of the acridine type, which have been attached at the 4-position of the azolyl ring using appropriate methylenic linkers. The synthesis, characterization and in vitro evaluation of the respective $\operatorname{Re}(\mathrm{I}) /{ }^{99 \mathrm{~m}} \mathrm{Tc}(\mathrm{I})$ tricarbonyl complexes will be also presented. This includes the study of the interaction with CT-DNA by a variety of spectroscopic techniques, fluorescence microscopy studies, intracellular distribution studies and evaluation of damage in plasmid DNA.

## Results and discussion

## Synthesis of pyrazolyl containing chelators bearing acridine derivatives and respective metal complexes

Two pyrazolyl diamine chelators bearing acridine derivatives at the 4-position of the pyrazolyl ring ( $\mathbf{L} 1$ and $\mathbf{L 2}$ ) were synthesized as depicted in Scheme 1. A first step consisted of the synthesis of 10-(4-amino-butyl)-3,6-bis-dimethylamino-acridinium (1) and $N$-(4-aminobuthyl)acridine-9-carboxamide (2), prepared respectively, from the commercially available acridine orange and 9 -acridine carboxylic acid and following described methodologies. ${ }^{13}$ Then, chromophores $\mathbf{1}$ and 2 were conjugated to the protected and activated pyrazolyl-diamine derivative $\mathbf{3}$, recently synthesized and characterized in our group. ${ }^{14}$ Such conjugation was successfully done in dry DMF, in the presence of DIPEA, at room temperature and after five days of reaction. After appropriate work-up, compounds $\mathbf{4}$ and $\mathbf{5}$ were obtained as a dark orange and yellow oil, respectively. The Boc protecting group was then removed by overnight reaction of $\mathbf{4}$ and 5 with TFA in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, at room temperature. The unprotected conjugates were dried under reduced pressure and the crude purified by washing with ethyl acetate ( $\mathbf{L} \mathbf{1}$ ) or with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ followed by column chromatography purification (L2). Compounds $\mathbf{L} 1$ and $\mathbf{L 2}$ were then obtained as
a red-orange solid ( $83 \%$ yield) or as a yellow oil ( $84 \%$ yield), respectively.
The new compounds $\mathbf{L 1} \mathbf{- L 2}$ were characterized by multinuclear NMR spectroscopy $\left({ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\right.$ and $\left.{ }^{18} \mathrm{~F}\right)$, ESI-MS, elemental analysis and HPLC. In the ${ }^{1} \mathrm{H}$ NMR spectra of $\mathbf{L} 1$ and $\mathbf{L} \mathbf{2}$ the resonances due to the acridine units were easily identified between $6.5-8.6 \mathrm{ppm}$ for $\mathbf{L} 1$ and $7.5-8.1 \mathrm{ppm}$ for $\mathbf{L 2}$, while the methylenic protons of the diamine framework appear between 3 and 4.3 ppm for L1 and between 2.6 and 4.0 ppm for $\mathbf{L 2}$. For both compounds, two resonances, integrating for three protons each, appear for the 3,5$\mathrm{Me}_{2}$ groups of the pyrazolyl ring (at approx. 2 ppm ), while the methylenic protons at the 4-position of the same ring appear at about 3.2 ppm . The butylenic protons of the linker between the pyrazolyl diamine framework and the acridine units appear at $1.82(2 \mathrm{H}), 1.98(2 \mathrm{H}), 3.23(2 \mathrm{H}$, overlapping with Me groups of the chromophore), and $4.70(2 \mathrm{H}) \mathrm{ppm}$ for $\mathbf{L 1}$ and at $1.70(4 \mathrm{H}), 2.16$ $(2 \mathrm{H})$ and $3.61(2 \mathrm{H}) \mathrm{ppm}$ for $\mathbf{L 2}$. In the ${ }^{13} \mathrm{C}$ NMR spectra all the expected resonances could be identified, including the ones due to the TFA. By HPLC one single peak was found for each compound, with retention times of 14.99 min and 10.95 min for $\mathbf{L} 1$ and $\mathbf{L 2}$, respectively. In the positive mode, the ESI-MS spectra showed prominent peaks at $m / z$ values corresponding to the expected molecular ions: $[\mathrm{M}]^{+}=559.1$ for $\mathbf{L} 1$ and $[\mathrm{M}+\mathrm{H}]^{+}=516.1$ for $\mathbf{L 2}$.

Reactions of $f a c-\left[\operatorname{Re}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}(\mathrm{CO})_{3}\right] \mathrm{Br}$ with $\mathbf{L} \mathbf{1}$ and $\mathbf{L} 2$ in refluxing methanol, followed by column chromatography purification, led to the cationic tricarbonyl complexes Re1 and Re2 (Scheme 2).

Complexes Re1 and Re2 are red-orange and yellow solids, respectively. They are stable towards air oxidation or hydrolysis and are soluble in water and MeOH . Their characterization was based on IR and multinuclear NMR spectroscopy, ESI-MS, elemental analysis and HPLC. The IR spectra showed intense absorption bands in the range $1890-2024 \mathrm{~cm}^{-1}$, easily assigned to the $v(\mathrm{C} \equiv \mathrm{O})$ stretching modes of the $f a c-\left[\operatorname{Re}(\mathrm{CO})_{3}\right]^{+}$unit. These frequencies compare well with the values found for other $\operatorname{Re}(\mathrm{I})$ tricarbonyl complexes anchored by pyrazolyl-diamine chelators of the same family. ${ }^{15}$ The ${ }^{1} \mathrm{H}$ NMR data obtained for Rel and $\mathbf{R e} \mathbf{2}$ indicate that $\mathbf{L} \mathbf{1}$ and $\mathbf{L 2}$ coordinate to the metal through the pyrazolyl-diamine framework, in a tridentate coordination mode. Such assignment was based mainly on the chemical shift and splitting of the two $-\mathrm{NH}_{2}$ protons which become diastereotopic after coordination to the metal ( 3.86 ppm and 5.41 ppm for Re1; 3.90 ppm and 5.39 ppm for Re2) and methylenic protons

Table 1 Labelling conditions, HPLC retention time and $\log P_{o / w}$ values for Tc1 and Tc2

| Complex | $t / \mathrm{min}$ | $T /{ }^{\circ} \mathrm{C}$ | $t_{\mathrm{R}} / \min ^{a}$ | $\log P_{0 / \mathrm{w}} \pm \mathrm{SD}$ |
| :--- | :--- | :--- | :--- | :--- |
| Tc1 | 40 | 100 | $17.92(17.69)$ | $0.56 \pm 0.02$ |
| Tc2 | 30 | 100 | $16.17(15.06)$ | $0.74 \pm 0.01$ |

${ }^{a}$ The retention time for the Re complexes are in parenthesis
of the pyrazolyl-diamine unit which also become diastereotopic originating eight resonances, integrating for one proton each, in the range 2.40 ppm and 4.60 ppm . The pattern obtained is comparable to the one found for other complexes stabilized with chelators of the same family. In Re1 and Re2 the resonances from the pyrazolyl-diamine framework exhibit chemical shifts significantly different from those of the corresponding protons in the respective free ligands. In contrast, the signals due to the protons of the chromophoric units, as well as those due to the methylenic and butylenic linkers between the chromophores and the pyrazolyl-diamine backbone, present a splitting and chemical shifts very similar to those of the free ligands, confirming that the chromophore units don't interact with the metal center. In the positive mode, prominent peaks with the expected isotopic pattern could be found in the ESI-MS spectra of Re1 and Re2 at $\mathrm{m} / \mathrm{z} 414.9\left([\mathrm{M}]^{2+}\right)$ and $786.0\left([\mathrm{M}]^{+}\right)$, respectively. The synthesis of the ${ }^{99 \mathrm{~m}} \mathrm{Tc}$ complexes ( $\mathbf{T c} 1$ and $\mathbf{T c 2}$ ) was done in aqueous solution by reaction of $f a c-\left[{ }^{99 \mathrm{~m}} \mathrm{Tc}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}(\mathrm{CO})_{3}\right]^{+}$with the appropriate ligand ( $\mathbf{L} 1$ or $\mathbf{L 2}$ ) at $100^{\circ} \mathrm{C}$ for 30 to 40 min and pH 7.4 (Scheme 2). These complexes were obtained in almost quantitative yield (> 98\%) using a relatively low final concentration of ligand $\left(10^{-4} \mathrm{M}\right)$. The chemical identity of Tc1 and Tc2 was ascertained by comparison of their HPLC profiles with those of the corresponding rhenium complexes (Re1-Re2). The respective retention times are presented in Table 1. These radiocomplexes are stable under physiological conditions, including in the cell culture media (data not shown).

The lipophilicity of complexes Tc1 and Tc2 was assessed by measurement of the respective $\log P_{\mathrm{o} / \mathrm{w}}$ values ( n -octanol/ 0.1 M PBS, pH 7.4) using the multiple back extraction method. ${ }^{16}$ The complexes Tc1 and Tc2 exhibited a hydrophobic character with $\log P_{\mathrm{o} / \mathrm{w}}$ values of $0.56 \pm 0.02$ and $0.74 \pm 0.01$, respectively (Table 1).

Fig. 1 Absorption spectra of $\mathbf{L} 1\left(4.25 \times 10^{-5} \mathrm{M}\right)$ and $\operatorname{Re} 1\left(1.5 \times 10^{-5} \mathrm{M}\right)$ in the presence of increasing amounts of CT-DNA $(0.02,0.04,0.06,0.08,0.13$, $0.17,0.23$ and 0.33 mM for $\mathbf{L 1} ; 0.01,0.02,0.04,0.05,0.07,0.10,0.14,0.21$ and 0.40 mM for Re1) in Tris- HCl 0.1 M buffer.

## DNA-binding studies

The interaction of $\mathbf{L} 1, \mathbf{L 2}, \mathbf{R e} \mathbf{1}$ and $\mathbf{R e} \mathbf{2}$ with CT-DNA was evaluated by UV-visible, fluorescence, CD and LD spectroscopies. These studies consisted of monitoring the changes of the bands due to the acridine chromophores upon addition of increasing amounts of DNA.

## UV-visible spectroscopy

From the UV-visible titration of compounds L1 and Re1 (Fig. 1) it was observed that the absorption peak of the free compounds present a maximum at 496 nm , which is red shifted upon binding of DNA (maximum at 506 nm ). Additionally, the shoulder observed at 470 nm changed to 480 nm after interaction of the species with the DNA double helix. This red shift $(\Delta \lambda=10 \mathrm{~nm})$ is in agreement with the results reported by other authors for acridine orange (AO) and for a $\mathrm{Pt}(\mathrm{II})$ complex bearing a pendant AO fragment, and is consistent with an intercalative binding of the compounds. ${ }^{17-19}$ As the DNA concentration increases, the shoulder at 470 nm diminishes in intensity. Such a shoulder can be assigned to the
presence of dimeric species, resulting from the self-association of AO rings, their formation being less probable when the compounds bind to DNA. The shape and intensity of the band at 506 nm due to the bound compounds remained fairly constant, indicating that L1 and Re1 act most probably as intercalated monomers without any interaction between themselves.

The UV-vis spectra of L2 and Re2 (see Fig. S1 in Supplementary Information) show an absorption maximum at 359 nm . Upon addition of CT-DNA, there is a moderate hypochromicity but no bathochromic shift is observed. These findings indicate that these compounds have a low propensity to interact with DNA by intercalation.

## Fluorescence spectroscopy

The addition of DNA to solutions of $\mathbf{L 1}$ and Re1 led to the increase of the emission intensity until a saturation value was reached (Fig. 2). Such enhancement of fluorescence clearly indicates the intercalation of the AO moiety of compounds L1 and Re1 into the DNA double helix, as claimed by other authors for different AO derivatives. ${ }^{13,17}$

Fig. 2 Fluorescence spectra of $\mathbf{L} 1\left(1.06 \times 10^{-5} \mathbf{M}\right.$, left) and $\operatorname{Re} \mathbf{1}\left(1.5 \times 10^{-6} \mathbf{M}\right.$, right) in the presence of increasing amounts of CT-DNA (5.6, 8.4, 11.1, $13.9,16.6,21.5,26.4,36.0,50.1$ and $59.3 \mu \mathrm{M}$ for $\mathbf{L 1} ; 4.0,7.8,11.7,15.5,19.3,23.1,30.1,37.0,50.6,70.4$ and $83.2 \mu \mathrm{M}$ for Re1) in Tris-HCL 0.1 M buffer. Excitation at 470 nm .

Fig. 3 ICD spectra of compounds $\mathbf{L 1}$ (left) and Re1 (right) at several ratios of [DNA]/[probe] concentrations for a CT-DNA concentration of $2.5 \times$ $10^{-5} \mathrm{M} \mathrm{nucl}^{-1}$ : A) 0.2 eq. of probe; B) 2 eq. of probe.

For $\mathbf{L 2}$ and $\mathbf{R e 2}$, the addition of DNA induces a quenching of the fluorescence (Fig. S2, S. I.), as commonly found for acridine derivatives due to an energetically favorable electron-transfer reaction from the DNA bases to the acridine moiety. ${ }^{20}$ However, only a slight fluorescence quenching was observed, particularly in the case of Re2. This certainly reflects the low affinity of these compounds to DNA, as already indicated by the UV-vis experiments.

## Induced circular (CD) and linear dichroism (LD)

The compounds L1, $\mathbf{R e} \mathbf{1}$ and $\mathbf{L 2}, \mathbf{R e} \mathbf{2}$ do not present CD spectra, in agreement with the expected non-chirality of the molecules. However, their association with the right-handed DNA helix should led to ICD spectra in the range where the acridine or AO chromophores absorb ( $400-525 \mathrm{~nm}$ ). From the compounds studied, only L1 and Re1 show positive ICD spectra in the expected spectral range (Fig. 3), as a result of the close proximity between the chromophores and the biomolecule. For 0.2 equivalents of DNA we have observed one positive band at 516 nm and two negative bands at 475 nm and 489 nm with intensities varying greatly with increasing amounts of the chromophores. These bands can be assigned to intercalated compounds by comparison with the ICD spectra reported previously for AO bound to DNA. ${ }^{17}$

For compounds $\mathbf{L 2}$ and $\mathbf{R e} \mathbf{2}$ it was not possible to register any changes in the CD spectra of the species in the presence of CTDNA, showing once again the poor interaction ability of these compounds with the biomolecule.

LD studies were performed in order to get better information about the spatial orientation of the chromophore relative to the DNA double helix. Both L1 and Re1 induced a strong increase in the signal intensity for the DNA band ( $230-300 \mathrm{~nm}$ ) indicating that the DNA becomes more oriented within the hydrodynamic field upon interaction because of stiffening of the helix on intercalation of these compounds (Fig. 4). Furthermore, a negative signal also emerged in the chromophore region ( $400-525 \mathrm{~nm}$ ) which suggests an intercalation binding mode for $\mathbf{L 1}$ and Re1. The nearly constant value of $\mathrm{LD}_{\mathrm{r}}$ in this spectral range confirms the perfect intercalation for both species.

Table 2 Intrinsic binding constants $(K)$ for $\mathbf{L} 1$ and $\operatorname{Re} 1$

|  |  | $K / \mathrm{M}^{-1} \times 10^{5}$ |  |
| :--- | :--- | :--- | :--- |
| Spectroscopic technique | Model | L1 | Re1 |
| UV-Visible | Scatchard | $1.71 \pm 0.01$ | $2.50 \pm 0.01$ |
|  | Kaminoh | $1.75 \pm 0.15$ | $2.33 \pm 0.39$ |
| Fluorescence | Scatchard | $1.53 \pm 0.01$ | $2.26 \pm 0.01$ |
|  | Kaminoh | $1.93 \pm 0.22$ | $2.36 \pm 0.02$ |
|  | McGhee von Hippel | $1.93 \pm 0.86$ | $1.17 \pm 0.68$ |
|  |  | $n=2.7$ | $n=17.8$ |

For compounds $\mathbf{L 2}$ and $\mathbf{R e 2}$, the addition of DNA also led to the appearance of a negative band in the chromophore absorption region ( $300-400 \mathrm{~nm}$ ) (Fig. S3, S.I.). However, even for the highest concentrations of DNA, its intensity was much lower than the intensity of the bands induced by L1 and Re1. Therefore, the LD studies confirmed once again that compounds $\mathbf{L 2}$ and $\mathbf{R e} \mathbf{2}$ have a lower affinity towards the DNA double helix in comparison with $\mathbf{L 1}$ and Re1. The presence of these negative bands suggests that $\mathbf{L} \mathbf{2}$ and Re2 can intercalate into the DNA double helix. However, the $\mathrm{LD}_{\mathrm{r}}$ signal in this spectral range is largely wavelength dependent and its intensity is higher than that of DNA alone, indicating that these compounds are only partially intercalated.

## DNA binding constant

The data obtained for compounds L1 and Re1 in the UV-visible and fluorescence titrations were used to obtain the intrinsic binding constants ( $K$ ) (Table 2) by adjustment to different mathematical and computational models (see Experimental Section). Simple Scatchard and Kaminoh models were fitted to the UVvis and fluorescence data; the fluorescence data were also fitted to the non-cooperative McGhee von Hippel model. As discussed above, compounds $\mathbf{L 2}$ and $\mathbf{R e} \mathbf{2}$ revealed a poor interaction with the DNA and no model could be adjusted to determine the respective binding constants.

For L1, the adjustment of the McGhee von Hippel model gave a $K$ value of $(1.93 \pm 0.86) \times 10^{5} \mathrm{M}$ and a binding size site $(n)$ of

Fig. 4 Linear dichroism (LD, upper panels) and reduced linear dichroism (LDr, lower panels) of L1 (left) and Re1 (right) at different [DNA]/[probe] molar ratios: A) no probe; B) 25 ; C) 12 ; D) 5 . Spectra were recorded in 10 mM phosphate buffer at pH 7.2 .
2.7. These values are comparable with those reported for acridine orange, particularly in which concerns the $n$ value that is consistent with an intercalative binding of the molecule. ${ }^{21-23}$ By contrast, a large $n$ value (17.8) was determined for $\mathbf{R e} \mathbf{1}$ which indicates that the obtained data are not consistent with a nearest neighbor exclusion intercalation model. This might result from the involvement of different binding modes in the range of concentrations needed to reach saturation in the case of Re1. ${ }^{24}$ In fact, L1 reached saturation at $59.3 \mu \mathrm{M}$ of CT-DNA whereas Re1 required $83.2 \mu \mathrm{M}$ of CT-DNA to reach saturation. Complex Re1 has a larger net positive charge (+2) that may favor electrostatic interactions with the phosphate groups from the outer-part of the DNA double helix, justifying the highest DNA concentration needed to reach saturation.

As discussed above, the McGhee von Hippel model was not properly fitted to fluorescent data obtained for the DNA titration of Re1. Therefore, the binding constant calculated based on such adjustment should be considered with caution. In order to compare the DNA affinity of $\mathbf{L 1}$ and $\mathbf{R e 1}$, the respective binding constants ( $K$ ) were determined using Scatchard and Kaminoh models, based on the UV-vis and fluorescence data. Based on these models, the $K$ values determined for Re1, spanning between $(2.26 \pm 0.01) \times 10^{5}$ and $(2.50 \pm 0.01) \times 10^{5} \mathrm{M}^{-1}$, were consistently higher than those found for $\mathbf{L} 1\left((1.53 \pm 0.01) \times 10^{5}-(1.93 \pm 0.22) \times\right.$ $10^{5} \mathrm{M}^{-1}$ ). This certainly reflects the higher positive charge of Re1 that may favor electrostatic interactions with the DNA phosphate groups.

## Cellular and nuclear uptake studies

When designing a ${ }^{99 \mathrm{~m}} \mathrm{Tc}$-radiopharmaceutical, namely as a potential candidate for Auger electron therapy, it is very important to quantify the cellular and nuclear uptake of the compounds but is
also important to follow the trafficking of the compounds at cellular and subcellular level, in real time. The cell uptake quantification can be easily done using the radioactive ${ }^{99 \mathrm{~m}} \mathrm{Tc}$-complexes, but the trafficking can only be evaluated using analogous and fluorescent Re complexes.

Taking advantage of the fluorescence emission characteristics of the chromophore units of the newly synthesized compounds, the cellular uptake for the ligands $\mathbf{L} \mathbf{1}$ and $\mathbf{L} \mathbf{2}$ and the corresponding complexes, Re1 and Re2, was assessed by fluorescence microscopy in B16F1 murine melanoma cells. Compounds L1 and Re1 were detected by the emission of green fluorescence and the nuclear localization was evaluated by comparison with the nuclear stain DAPI. Compounds L2 and Re2 were detected by the emission of blue fluorescence and the nuclear localization was evaluated by comparison with the nuclear stain DRAQ5.
$\mathbf{L 1}$ and $\mathbf{R e} 1$ were detected in the cytoplasm and in the nucleus, specifically in the nucleoli (data not shown). L2 and Re2 also localize in the cytoplasm and in the nucleus of the cells but present a less intense emission of fluorescence. This lower emission intensity led to a lower definition of the images, due to the longer exposure time required for the capture (data not shown). Due to the promising results obtained for $\mathbf{L} \mathbf{1}$ and $\mathbf{R e} \mathbf{1}$ the cellular uptake of these compounds was further evaluated by confocal laserscanning fluorescence microscopy, which confirmed the cellular localization of L1 and Re1 in the cytoplasm and nucleus in association with the nucleoli (Fig. 5).
To quantify the cellular and nuclear internalization found for Re1 using fluorescence microscopy, we have studied the behavior of Tc1 with the same cell line. These studies were performed using B16F1 murine melanoma cells and the HPLC purified Tc1 complex.

The cellular internalization of $\mathbf{T c} \mathbf{1}$ was performed at $37^{\circ} \mathrm{C}$ and was time-dependent (Fig. 6). Moderate levels of internalization

Fig. 5 Uptake of compounds L1 and $\operatorname{Re} 1(70 \mu \mathrm{M})$ by B16F1 murine melanoma cells evaluated by confocal fluorescence microscopy (blue: nuclei; white arrows: nucleoli).
were reached. For example, at 5 h post-incubation a value of $7.8 \%$ was obtained, when internalization is expressed as a percentage of total activity (Fig. 6A). For the same time of incubation, approximately $34 \%$ of the bound activity (activity on the membrane and inside the cell) was taken up and internalized by the cells (Fig. 6B).

The cellular retention of $\mathbf{T c} \mathbf{1}$ was evaluated at different time points, after 3 h of internalization (Fig. 7). The radiocomplex was slowly released from the cells into the culture medium, with about $60 \%$ of the initially internalized complex still remaining inside the cells at 3 h post-incubation.

Nuclear internalization of compound Tc1 in B16F1 cells was also determined. The percentage of activity internalized into the nucleus per total activity is presented in Fig. 8A. At 6 h postincubation, $3.8 \%$ of the administered compound was internalized into the cell nucleus.
The nuclear internalization was also determined by the ratio between the activities internalized into the nucleus and the cellbound activity (Fig. 8B). Such calculation gives a more accurate measure of the ability of the complex to pass from the cytoplasm to the nucleus. As can be seen in Fig. 8B, the nuclear internalization is very fast and the percentage of compound inside the nucleus is higher than that outside (i.e., cytoplasm and cell membrane). After $30 \mathrm{~min}, 67.2 \%$ of $\mathbf{T c} 1$ was found in the nucleus. This shows that the radioactive compound rapidly diffuses to the cell nucleus after being internalized by the cell, reflecting most probably its affinity to DNA.

Fig. 7 Cellular retention of the internalized complex Tc1 in B16F1 cells over time at $37^{\circ} \mathrm{C}$ (mean $\pm$ standard deviation, $n=3$ ).

## Plasmid DNA studies

Since Rel was shown to interact strongly with CT-DNA and the congener Tc1 presented an enhanced ability to target the nucleus, we decided to evaluate if the Auger electrons emitted by ${ }^{99 \mathrm{~m}} \mathrm{Tc}$ would induce damage on plasmid DNA, upon formation of singlestrand breaks (SSB) or double-strand breaks (DSB). These studies were also performed for the congener $\mathbf{R e} \mathbf{1}$ and for [ $\left.{ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}\right]^{-}$, in order to check if the eventual damage is due to the radioactive character of Tc1 combined with its ability to intercalate into the DNA double helix. The non-radioactive Rel was evaluated in a $10^{-8} \mathrm{M}$ concentration, corresponding approximately to the molar concentration used for Tc1. Tc1 and $\left[{ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}\right]^{-}$were studied using the same amount of radioactivity ( $150-310 \mu \mathrm{Ci})$. Samples of $\left.{ }^{99 m} \mathrm{TcO}_{4}\right]^{-}$and complexes Re1 and Tc1 were incubated with plasmid DNA (puc19) and the formation of strand breaks was analyzed by agarose gel electrophoresis. As can be seen in Fig. 9, Tc1 (C and D) induced a more pronounced reduction of the supercoiled (sc) band intensity compared with complex $\operatorname{Re} \mathbf{1}(\mathrm{G})$ and with $\left[{ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}\right]^{-}$(E and F). The total plasmid DNA containing strand breaks corresponded to more than $30 \%$ in the case of Tc1, roughly to $15 \%$ for $\mathbf{R e} \mathbf{1}$ and to less than $6 \%$ for $\left[{ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}\right]^{-}$. For all the compounds, the damaged DNA is uniquely in the open

Fig. 6 Cellular internalization of Tc1 at $37^{\circ} \mathrm{C}$ in B 16 F 1 murine melanoma cells. A) Internalization expressed as a percentage of total activity; B) internalized and surface bound activity expressed as a fraction of cell-bound activity (mean $\pm$ standard deviation, $n=3$ ).

Fig. 8 Nuclear internalization of $\mathbf{T c} 1$ at $37^{\circ} \mathrm{C}$ in B 16 F 1 murine melanoma cells. A) Nuclear internalization expressed by total activity; B) activity inside the nucleus and outside the nucleus expressed as a percentage of cell-bound activity (mean $\pm$ standard deviation, $n=3$ ).

Fig. 9 Cleavage of supercoiled (sc) puc19 DNA, after 48 h of incubation at room temperature in Tris ( pH 7.4 ): $\mathbf{A}$ - molecular weight marker -1 Kb DNA ladder; B - control (DNA + buffer); C - DNA + Tc1, $310 \mu \mathrm{Ci}$; $\mathbf{D}$ - DNA $+\mathbf{T c 1}, 150 \mu \mathrm{Ci} ; \mathbf{E}-\mathrm{DNA}+\left[{ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}\right]^{-}, 310 \mu \mathrm{Ci} ; \mathbf{F}-\mathrm{DNA}+$ $\left.{ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}\right]^{-}, 150 \mu \mathrm{Ci} ; \mathbf{G}-\mathrm{DNA}+\operatorname{Re}\left(10^{-8} \mathrm{M}\right)$.
circular (oc) form, no linear form being detected. In summary, complex Tc1 induces more easily SSB in plasmid DNA compared with $\operatorname{Rel}$ and with $\left[{ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}\right]^{-}$. This probably reflects the expected high affinity of Tc1 to DNA and its ability to act as a perfect intercalator, taking into consideration the interaction studies with DNA performed for the isostructural Re1. However, Tc1 was unable to provoke DSBs as would be expected if the emission of Auger electrons by the ${ }^{99 \mathrm{~m}} \mathrm{Tc}$ radionuclide could occur in a close proximity to DNA. For ${ }^{125}$ I-labelled molecules, it has been reported in several instances that small changes in the position of the decay site may have strong effects on the yields of SSBs and DSBs. ${ }^{4}$ Eventually, the butylenic linker used to attach the AO fragment to the planar azolyl ring allows a perfect intercalation of the chromophore but is too long to assure the proximity of the radiometal to the DNA bases, necessary to have DSBs induced by the emitted Auger electrons.

## Concluding remarks

Novel pyrazolyl-diamine chelators bearing acridine derivatives at the 4 -position of the pyrazolyl ring have been synthesized and characterized (L1, L2) and used to prepare Re and ${ }^{99 \mathrm{~m}} \mathrm{Tc}$ tricarbonyl complexes ( $\mathbf{R e 1}, \mathbf{T c} 1, \mathbf{R e 2}, \mathbf{T c 2}$ ). The interaction of all these
compounds with CT-DNA was studied using different spectroscopic techniques. Based on UV-visible and fluorescence spectroscopy, as well as on circular and linear dichroism it was found that L1 and Re1 act as DNA intercalators, while $\mathbf{L 2}$ and $\mathbf{R e} \mathbf{2}$ have a much lower affinity towards the DNA double helix. Using different mathematical and computational models the results obtained on UV-visible and fluorescence were used to calculate intrinsic binding constants. For $\mathbf{L 2}$ and $\mathbf{R e 2}$ no model could be adjusted, certainly due to the poor interaction of these compounds with DNA. Using the McGhee von Hippel model, the $K$ and $n$ values obtained for $\mathbf{L} 1$ compare well with the ones reported previously for acridine orange, but the values found for Re1 must be taken with caution, mainly due to the high value found for the binding size site ( $n=17.8, \operatorname{Re} \mathbf{1}$ ), which may reflect the larger net positive charge of $\operatorname{Re} \mathbf{1}(+2)$. Based on the fluorescence emission of the AO and on the possibility of preparing analogous Re and Tc tricarbonyl complexes, it was found that $\operatorname{Re} 1$ and ${ }^{99 \mathrm{~m}} \mathbf{T c} 1$ internalize significantly and are retained in the nucleus of B 16 F 1 murine melanoma cells. Studies with plasmid DNA also confirm that Tc1 induces reduction of the sc band intensity, reflecting the expected high affinity of the complex to DNA, its ability to intercalate and the emission of Auger electrons. The absence of DSBs may indicate that a linker shorter than the butylenic one has to be explored in our studies, to assure a closer proximity of the radiometal to the DNA. The results presented herein, together with the stability and versatility of this type of complexes, encourage the synthesis of ${ }^{99 m} \mathrm{Tc}$ trifunctional complexes for cell-specific and DNA targeting, as well as the evaluation of their therapeutic effect as Auger-emitters.

## Experimental section

## Chemistry

All chemicals were of reagent grade. Solvents were dried and distilled prior to use according to described procedures. ${ }^{25}$ Unless stated otherwise, the syntheses of the ligands and complexes were carried under a nitrogen atmosphere, using standard Schlenk techniques and dry solvents; the work-up procedures were performed under air. Compounds 2-(4-bromobutyl)isoindoline-1,3-dione, ${ }^{26}$ and tert-butyl $N-(2-\{[($ tert-butoxy)carbonyl](2-\{4-[2-(2,5-dioxopyrrolidin-1-yl)-2-oxoethyl]-3,5-dimethylpyrazol-1yl \}ethyl)amino\}ethyl)carbamate (3) ${ }^{14}$ were prepared according to
published methods. The starting material fac- $\left[\mathrm{Re}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}(\mathrm{CO})_{3}\right] \mathrm{Br}$ was synthesized by the literature method. ${ }^{27}$
$\mathrm{Na}\left[{ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}\right]$ was eluted from a commercial ${ }^{99} \mathrm{Mo} /{ }^{99 \mathrm{~m}} \mathrm{Tc}$ generator, using $0.9 \%$ saline. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Varian Unity 300 MHz spectrometer; ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ chemical shifts are given in ppm and were referenced to the residual solvent resonances relative to $\mathrm{SiMe}_{4}$. The NMR samples were prepared in $\mathrm{CDCl}_{3}$ or $\mathrm{CD}_{3} \mathrm{OD}$. $J$ values are given in Hz . IR spectra were recorded in the range $4000-200 \mathrm{~cm}^{-1}$ as KBr pellets on a Bruker Tensor 27 spectrometer. Electrospray ionisation mass spectrometry (ESI-MS) was performed using a Bruker HCT electrospray ionization quadrupole ion trap mass spectrometer. Elemental analyses were performed on a Perkin-Elmer automatic analyser.
Thin layer chromatography (TLC) was done on Merck silica gel 60 F254 plates. Column chromatography was performed with silica gel 60 (Merck). HPLC analysis of the ligands, Re complexes and ${ }^{99 \mathrm{~m}} \mathrm{Tc}$ complexes was performed on a Perkin-Elmer LC pump 200 coupled to a LC 290 tunable UV-vis detector and to a Berthold LB-507A radiometric detector, using an analytic Macherey-Nagel C18 reversed-phase column Nucleosil 100-5, $250 \times 4 \mathrm{~mm}$, with a flow rate of $0.9 \mathrm{~mL} \mathrm{~min}{ }^{-1}$; UV detection, 254 nm ; eluents, A: aqueous $0.1 \% \mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}$ solution, B : acetonitrile; method: $0-3 \mathrm{~min}, 100 \% \mathrm{~A} ; 3-3.1 \mathrm{~min}, 100 \%-75 \% \mathrm{~A} ; 3.1-9 \mathrm{~min}, 75 \%$ A; 9-9.1 min $75 \%-66 \%$ A; $9.1-18 \mathrm{~min}, 66 \%-0 \% \mathrm{~A} ; 18-25 \mathrm{~min}$, $0 \% \mathrm{~A} ; 25-25.1 \mathrm{~min}, 0 \%-100 \% \mathrm{~A} ; 25.1-30 \mathrm{~min}, 100 \%$ A. HPLC purification of the radioactive compound was done with a semipreparative Macherey-Nagel EP $250 \times 8$ Nucleosil 100-7 C18 reversed-phase column at a flow rate of $2.0 \mathrm{~mL} \mathrm{~min}{ }^{-1}$ using the same methodology as for analytical HPLC. Radioactivity measurements were done using a ionization chamber Aloka, Curiemeter IGC-3 or a $\gamma$-counter Berthold, LB 2111.

## Synthesis of the bifunctional ligands L1 and L2

10-(4-Amino-butyl)-3,6-bis-dimethylamino-acridinium (1). pXylol $\left(90 \mathrm{~cm}^{3}\right)$ was added to acridine orange ( $1 \mathrm{~g}, 3.769 \mathrm{mmol}$ ) and 2-(4-bromobutyl)isoindoline-1,3-dione ( $3.2 \mathrm{~g}, 11.306 \mathrm{mmol}$ ) and refluxed overnight. The reaction mixture was filtered and the solid obtained was washed with acetone, dried under reduced pressure and purified by column chromatography (eluent: $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $98-80 \%$ )/ $\mathrm{MeOH}(2-20 \%)$ ) giving 3,6-bis(dimethylamino)-10-(4-(1,3-dioxoisoindolin-2-yl)butyl)acridinium ( $0.597 \mathrm{~g}, 31 \%$ ) as a red-orange solid. $\delta_{\mathrm{H}}\left(300 \mathrm{MHz} ; \mathrm{CDCl}_{3} ; \mathrm{Me}_{4} \mathrm{Si}\right) 1.90(2 \mathrm{H}, \mathrm{m}$, $\left.\mathrm{CH}_{2}\right), 2.06\left(2 \mathrm{H}, \mathrm{t}, J 6.6, \mathrm{CH}_{2}\right), 3.25\left(12 \mathrm{H}, \mathrm{s}, 4 \mathrm{CH}_{3}\right), 3.80(2 \mathrm{H}$, $\left.\mathrm{t}, J 6.6, \mathrm{CH}_{2}\right), 4.88\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 6.51(2 \mathrm{H}, \mathrm{s}, 2 \mathrm{CH}-\mathrm{Ar}), 6.94$ ( $2 \mathrm{H}, \mathrm{d}, J 8.7,2 \mathrm{CH}-\mathrm{Ar}$ ), $7.68(2 \mathrm{H}, \mathrm{m}, 2 \mathrm{CH}-\mathrm{Ar}), 7.74(2 \mathrm{H}$, m, 2CH-Ar), 7.81 ( $2 \mathrm{H}, \mathrm{d}, J 8.7,2 \mathrm{CH}-\mathrm{Ar}$ ), $8.63(1 \mathrm{H}, \mathrm{s}, \mathrm{CH}-$ Ar). Hydrazine hydrate ( $0.471 \mathrm{~g}, 9.416 \mathrm{mmol}$ ) was added to a suspension of 3,6-bis(dimethylamino)-10-(4-(1,3-dioxoisoindolin-2-yl)butyl)acridinium in a mixture of methanol and ethanol (3:1) and refluxed overnight. After addition of $4 \mathrm{~cm}^{3}$ of concentrated $\mathrm{HCl}(37 \%)$ a white solid of phthalic acid hydrazide precipitated. After filtration the pH of the solution was adjusted to about 9 with 3 M NaOH . The reaction mixture was extracted with chloroform $\left(3 \times 50 \mathrm{~cm}^{3}\right)$ and the combined organic phases were dried over $\mathrm{MgSO}_{4}$ and evaporated under reduced pressure to give $1(0.450 \mathrm{~g}$, $95 \%$ ) as a red-orange solid. $\delta_{\mathrm{H}}\left(300 \mathrm{MHz} ; \mathrm{CD}_{3} \mathrm{OD} ; \mathrm{Me}_{4} \mathrm{Si}\right) 1.95$ $\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 2.08\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 3.01\left(2 \mathrm{H}, \mathrm{t}, J 6.9, \mathrm{CH}_{2}\right), 3.33$
$\left(12 \mathrm{H}, \mathrm{s}, 4 \mathrm{CH}_{3}\right), 4.78\left(2 \mathrm{H}, \mathrm{t}, J 8.1, \mathrm{CH}_{2}\right), 6.68(2 \mathrm{H}, \mathrm{d}, J 2.1,2 \mathrm{CH}-$ Ar), $7.26(2 \mathrm{H}, \mathrm{dd}, J 2.1, J 2.4$ and $J 9.0,2 \mathrm{CH}-\mathrm{Ar}), 7.90(2 \mathrm{H}$, d, $J 9.3,2 \mathrm{CH}-\mathrm{Ar}), 8.66(1 \mathrm{H}, \mathrm{s}, \mathrm{CH}-\mathrm{Ar}) ; \delta_{\mathrm{C}}\left(75.4 \mathrm{MHz} ; \mathrm{CD}_{3} \mathrm{OD}\right.$; $\left.\mathrm{Me}_{4} \mathrm{Si}\right) 24.42\left(\mathrm{CH}_{2}\right), 26.40\left(\mathrm{CH}_{2}\right), 40.57\left(\mathrm{CH}_{2}\right), 40.95\left(4 \mathrm{CH}_{3}\right), 47.69$ $\left(\mathrm{CH}_{2}\right), 93.61$ (2CH-Ar), 115.43 (2CH-Ar), 118.38 (2C-Ar), 134.38 (2CH-Ar), 143.95 (2C-Ar), 144.30 (CH-Ar), 157.32 (2C-Ar).
$\boldsymbol{N}$-(4-Aminobutyl)acridine-9-carboxamide (2). After being stirred for two hours at room temperature, a suspension of 9-acridine carboxylic acid ( $0.460 \mathrm{~g}, 2.061 \mathrm{mmol}$ ) and benzotriazole-1-yl-oxy-tris-(dimethylamino)-phosphonium hexafluorophosphate (BOP) $(1 \mathrm{~g}, 2.261 \mathrm{mmol})$ in $25 \mathrm{~cm}^{3}$ of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, was cooled to $0{ }^{\circ} \mathrm{C}$ and 1,4 -diamino butane $\left(1 \mathrm{~cm}^{3}, 10.275\right.$ mmol ) was added drop by drop. The reaction mixture was stirred again for 2 days at room temperature. The solvent was removed and the residue was purified by column chromatography (eluent: $\mathrm{CHCl}_{3}(95-0 \%) / \mathrm{MeOH}(5-80 \%) / \mathrm{NH}_{4} \mathrm{OH} 25 \%(0-20 \%)$ ) to give $5(0.415 \mathrm{~g}, 69 \%)$ as a yellow solid. $\delta_{\mathrm{H}}\left(300 \mathrm{MHz} ; \mathrm{CD}_{3} \mathrm{OD} ; \mathrm{Me}_{4} \mathrm{Si}\right)$ $1.79\left(4 \mathrm{H}, \mathrm{m}, 2 \mathrm{CH}_{2}\right), 2.85\left(2 \mathrm{H}, \mathrm{t}, J 6.9, \mathrm{CH}_{2}\right), 3.65(2 \mathrm{H}, \mathrm{t}, J 6.3$, $\left.\mathrm{CH}_{2}\right), 7.67(2 \mathrm{H}, \mathrm{m}, 2 \mathrm{CH}-\mathrm{Ar}), 7.87(2 \mathrm{H}, \mathrm{m}, 2 \mathrm{CH}-\mathrm{Ar}), 8.06(2 \mathrm{H}, \mathrm{d}, J$ $8.7,2 \mathrm{CH}-\mathrm{Ar}), 8.19(2 \mathrm{H}, \mathrm{d}, J 9.0,2 \mathrm{CH}-\mathrm{Ar}) ; \delta_{\mathrm{C}}\left(75.4 \mathrm{MHz} ; \mathrm{CD}_{3} \mathrm{OD}\right.$; $\left.\mathrm{Me}_{4} \mathrm{Si}\right) 27.72\left(\mathrm{CH}_{2}\right), 29.51\left(\mathrm{CH}_{2}\right), 40.76\left(\mathrm{CH}_{2}\right), 41.51\left(\mathrm{CH}_{2}\right), 123.65$ (2C-Ar), 126.56 (2CH-Ar), 128.21 (2CH-Ar), 129.56 (2CH-Ar), 132.05 (2CH-Ar), 132.33 (C-Ar), 149.57 (2C-Ar), 169.21 (C=O).

10-(4-(2-(1-(2-tert-Butoxycarbonyl(2-(tert-butoxycarbonylamino) ethyl) amino) ethyl)-3,5-dimethylpyrazol-4-yl) acetamido)-butyl)-3,6-bis(dimethylamino)acridinium (4). To a solution of $1(0.045 \mathrm{~g}, 0,107 \mathrm{mmol})$ in dry DMF $\left(20 \mathrm{~cm}^{3}\right)$ kept stirring for one hour at room temperature, was added a solution of $3(0.055 \mathrm{~g}, 0.102 \mathrm{mmol})$ and DIPEA ( $19 \mu \mathrm{l}, 0.107 \mathrm{mmol}$ ) in DMF ( $15 \mathrm{~cm}^{3}$ ). After five days the solvent was removed under reduced pressure and the dry residue obtained was purified by column chromatography (eluent: $\mathrm{CHCl}_{3}(95-60 \%) / \mathrm{MeOH}$ (5$35 \%) / \mathrm{NH}_{4} \mathrm{OH} 25 \%(0-5 \%)$ ) to give $4(0.054 \mathrm{~g}, 63 \%)$ as a dark orange solid. $\delta_{\mathrm{H}}\left(300 \mathrm{MHz} ; \mathrm{CDCl}_{3} ; \mathrm{Me}_{4} \mathrm{Si}\right) 1.35\left(18 \mathrm{H}, \mathrm{m}, 6 \mathrm{CH}_{3}\right.$ (BOC)), $1.95\left(4 \mathrm{H}, \mathrm{m}, 2 \mathrm{CH}_{2}\right), 2.07\left(6 \mathrm{H}, \mathrm{m}, 2 \mathrm{CH}_{3}\right), 3.05(4 \mathrm{H}, \mathrm{m}$, $\left.2 \mathrm{CH}_{2}\right), 3.31\left(18 \mathrm{H}, \mathrm{m}, 3 \mathrm{CH}_{2}, 4 \mathrm{CH}_{3}\right), 3.99\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 4.70$ $\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 5.27(1 \mathrm{H}, \mathrm{s} \mathrm{br}, \mathrm{NH}), 5.73(1 \mathrm{H}, \mathrm{s}, \mathrm{br}, \mathrm{NH}), 6.57$ ( $2 \mathrm{H}, \mathrm{s}, 2 \mathrm{CH}-\mathrm{Ar}$ ), $6.97(2 \mathrm{H}, \mathrm{d}, J 9.0,2 \mathrm{CH}-\mathrm{Ar}), 7.75(2 \mathrm{H}, \mathrm{t}, J 8.7$ and $J 9.0,2 \mathrm{CH}-\mathrm{Ar}), 8.47(1 \mathrm{H}, \mathrm{d}, J 15.9, \mathrm{CH}-\mathrm{Ar}) ; \delta_{\mathrm{C}}(75.4 \mathrm{MHz}$; $\left.\mathrm{CDCl}_{3} ; \mathrm{Me}_{4} \mathrm{Si}\right) 9.14\left(\mathrm{CH}_{3}\right), 11.37\left(\mathrm{CH}_{3}\right), 17.95\left(\mathrm{CH}_{2}\right), 25.03\left(\mathrm{CH}_{2}\right)$, $27.77\left(3 \mathrm{CH}_{3}, \mathrm{BOC}\right), 30.74\left(\mathrm{CH}_{2}\right), 38.91\left(\mathrm{CH}_{2}\right), 40.46\left(4 \mathrm{CH}_{3}\right), 41.68$ $\left(\mathrm{CH}_{2}\right), 47.45\left(\mathrm{CH}_{2}\right), 53.23\left(2 \mathrm{CH}_{2}\right), 57.13\left(\mathrm{CH}_{2}\right), 78.42(\mathrm{C}-\mathrm{BOC})$, 79.31 (C-BOC), $92.13(2 \mathrm{CH}-\mathrm{Ar}), 109.89\left(\mathrm{C}_{4 \mathrm{pz}}\right), 113.55(2 \mathrm{CH}-\mathrm{Ar})$, 116.52 (2C-Ar), 132.86 (2CH-Ar), $137.48\left(\mathrm{C}_{3 / 5-\mathrm{pz}}\right), 142.05(2 \mathrm{C}-\mathrm{Ar})$, $146.11\left(\mathrm{C}_{3 / 5 \text {-pz }}\right), 155.08$ (2CH-Ar), 155.60 ( $2 \mathrm{C}=\mathrm{O}, \mathrm{BOC}$ ), 171.29 ( $\mathrm{C}=\mathrm{O}$ ).

10-(4-(2-(1-(2-(2-Aminoethylamino)ethyl)-3,5-dimethyl-1H-pyrazol-4-ylacetamido)butyl)-3,6-bis(dimethylamino))acridinium (L1). $4(0.244 \mathrm{~g}, 0.290 \mathrm{mmol})$ was dissolved in a mixture of TFA ( $2 \mathrm{~cm}^{3}, 25.960 \mathrm{mmol}$ ) and $\mathrm{CH}_{2} \mathrm{Cl}_{2}(1: 1)$ and stirred at room temperature overnight. After that period of time the solvent was removed under reduced pressure and the solid was washed with ethyl acetate to give $\left.\mathbf{L} \mathbf{(} \mathbf{C F}_{3} \mathbf{C O}_{2}\right) \cdot \mathbf{3 . 5 T F A}(0.258 \mathrm{~g}$, $0.241 \mathrm{mmol}, 83 \%$ ) as a red-orange solid (Found: C, $45.29 ; \mathrm{H}$, 5.27; N, 11.04. $\mathrm{C}_{34} \mathrm{H}_{47} \mathrm{~F}_{3} \mathrm{~N}_{8} \mathrm{O}_{2} \cdot 3.5\left(\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}\right)$ requires C , 45.94; $\mathrm{H}, 4.76 ; \mathrm{N}, 10.46 \%) ; \delta_{\mathrm{H}}\left(300 \mathrm{MHz} ; \mathrm{CD}_{3} \mathrm{OD} ; \mathrm{Me}_{4} \mathrm{Si}\right) 1.82(2 \mathrm{H}, \mathrm{m}$, $\left.\mathrm{CH}_{2}\right), 1.98\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 2.03\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}\right), 2.15\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}\right)$,

## General procedure for the synthesis of the ${ }^{99 \mathrm{~m}} \mathrm{Tc}$ complexes (Tc1-Tc2)

In a glass vial, $100 \mu \mathrm{l}$ of a $10^{-4} \mathrm{M}$ aqueous solution of $\mathbf{L 1}$ $\mathbf{L 2}$ were added to $900 \mu \mathrm{l}$ of the organometallic precursor fac$\left[{ }^{99 \mathrm{~m}} \mathrm{Tc}(\mathrm{CO})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right]^{+}(1-2 \mathrm{mCi})$ in saline at pH 7.4 . The reaction
mixture was heated to $100{ }^{\circ} \mathrm{C}$ for 30 to 40 min , cooled at room temperature and the final solution analyzed by RP-HPLC.

## Partition coefficient measurements

The $\log P_{\mathrm{o} / \mathrm{w}}$ values of complexes $\mathbf{T c} \mathbf{1}-\mathbf{T c} 2$ (Table 1) were determined by the "shake flask" method under physiological conditions (n-octanol/0.1 M PBS, pH 7.4). ${ }^{16}$ The HPLC-purified compounds ( $100 \mu \mathrm{l}, \sim 100 \mu \mathrm{Ci}$ ) were added to a test tube containing 1 ml of n octanol and 1 ml of the PBS solution. The tube was vortexed for 1 min and centrifuged for 5 min at 3500 rpm . After centrifugation, $500 \mu \mathrm{l}$ of the organic phase were transferred to another tube and further extracted with $500 \mu$ of the PBS solution, as described for the first extraction. After separation of the phases, $50 \mu 1$ aliquots of each phase were taken for radioactivity measurement (in duplicate) using a $\gamma$-counter. The partition coefficient $\left(P_{\mathrm{o} / \mathrm{w}}\right)$ was calculated based on the ratio (activity in octanol layer)/(activity in aqueous layer) and is expressed as $\log P_{\mathrm{o} / \mathrm{w}}$.

## DNA binding studies

Calf thymus DNA (CT-DNA) sodium salt was purchased from Sigma and was used without further purification. The DNA concentrations per nucleotide of stock solutions in Tris buffer (Tris$\mathrm{HCl} 0.1 \mathrm{M}, \mathrm{pH} 7.4$ ) were determined by absorption spectroscopy at 260 nm , after adequate dilution with the buffer and using the reported molar absorptivity of $6600 \mathrm{M}^{-1} \mathrm{~cm}^{-1} .{ }^{28}$ The purity of the DNA samples was checked by monitoring the value $A_{260} / A_{280}$ ratio. All measurements that involved DNA and the different tested compounds (L1, L2, Re1 and Re2) were carried out in Tris buffer (Tris- $\mathrm{HCl} 0.1 \mathrm{M}, \mathrm{pH} 7.4$ ) or in phosphate buffer ( $10 \mathrm{mM}, \mathrm{pH} 7.2$ ).

The absorption and fluorescence titrations were performed by keeping the concentrations of the probe constant, while varying the concentrations of the DNA. To obtain the intrinsic binding constant ( $K$ ) all calculations were done by considering the DNA concentration in base pairs, and the data were corrected for volume changes.

## Absorption spectroscopy studies

UV-Vis absorption spectra were recorded on a Hitachi U-2000 spectrophotometer by using 1 cm path-length quartz cells. In order to eliminate any interference of the DNA absorbance in the region of absorbance of the acridine derivative chromophores an equal amount of CT-DNA in Tris buffer was added to the sample and reference cells. After each addition of CT-DNA, the solution was allowed to equilibrate and the absorption spectrum was recorded until there were no further changes in the absorbance.
According to the Scatchard model ${ }^{29}$ the absorption titration data were fitted to eqn (1) where $D$ is the concentration of DNA in base pairs and $\Delta \varepsilon_{\mathrm{ap}}=\left[\varepsilon_{\mathrm{a}}-\varepsilon_{\mathrm{F}}\right]$ and $\Delta \varepsilon=\left[\varepsilon_{\mathrm{B}}-\varepsilon_{\mathrm{F}}\right]$.

$$
\begin{equation*}
D / \Delta \varepsilon_{\mathrm{ap}}=D / \Delta \varepsilon+1 / \Delta \varepsilon K \tag{1}
\end{equation*}
$$

The apparent extinction coefficient, $\varepsilon_{a}$, is the ratio of the observed absorbance of the sample and the total concentration of the probe ( $A_{\text {obs }} /[$ probe] $) . \varepsilon_{\mathrm{B}}$ and $\varepsilon_{\mathrm{F}}$ correspond to the extinction coefficients of the bound and free forms of the probe, respectively. The intrinsic binding constant $(K)$ was determined from the plot of $D / \Delta \varepsilon_{\text {ap }} v s$. $D$.

According to the Kaminoh model ${ }^{30}$ the absorption titration data were fitted to eqn (2).

$$
\begin{equation*}
A=\left(A_{0}+K[\mathrm{DNA}] A_{\text {sat }}\right) /(1+K[\mathrm{DNA}]) \tag{2}
\end{equation*}
$$

As the concentration of the chromophore and its absorbance in solution $\left(A_{0}\right)$ are known, the value in saturation, $A_{\text {sat }}$, is calculated from the representation of $A v s$. [DNA].

## Fluorescence spectroscopy studies

Fluorescence spectra were recorded in a Perkin-Elmer LS50B spectrofluorimeter using a quartz cuvette of 1 cm . After each addition of CT-DNA in Tris buffer, the solution was allowed to equilibrate and the absorption at the excitation wavelength was recorded. The fluorescence spectra were then recorded until there were no further changes in the fluorescence intensity. Compounds $\mathbf{L 1}$ and $\mathbf{R e} 1$ were excited at 470 nm , while compounds $\mathbf{L 2}$ and $\mathbf{R e} \mathbf{2}$ were excited at 359 nm . Emission and excitation slits were chosen in order to maximize the fluorescence intensity. Emission spectra were recorded from $\lambda=400-700 \mathrm{~nm}$ for compounds L1 and Re1, and from $\lambda=350-650 \mathrm{~nm}$ for compounds $\mathbf{L} 2$ and Re2, with a scan speed of $150 \mathrm{~nm} \mathrm{~min}{ }^{-1}$. The fluorescence data were also used to determine the intrinsic binding constant $(K)$ of the probes.
According to the Scatchard model ${ }^{29}$ the data were fitted to eqn (3) where $D$ is the concentration of DNA in base pairs and $\Delta I_{\text {ap }}=$ $\left[I_{\text {ap }}-I_{\mathrm{F}}\right]$ and $\Delta I=\left[I_{\mathrm{B}}-I_{\mathrm{F}}\right]$.

$$
\begin{equation*}
D / \Delta I_{\mathrm{ap}}=D / \Delta I+1 / \Delta I K \tag{3}
\end{equation*}
$$

The apparent emission intensity, $I_{\mathrm{a}}$, is the ratio of the observed intensity of the sample and the total concentration of the probe ( $I_{\text {obs }} /[$ probe $]$ ). $I_{\mathrm{B}}$ and $I_{\mathrm{F}}$ correspond to the emission intensities of the bound and free forms of the probe, respectively. The intrinsic binding constant ( $K$ ) was determined from the plot of $D / \Delta I_{\mathrm{ap}} v s$. D.

According to the Kaminoh model ${ }^{30}$ the data were fitted to eqn (4).

$$
\begin{equation*}
I=\left(I_{0}+K[\mathrm{DNA}] I_{\mathrm{sat}}\right) /(1+K[\mathrm{DNA}]) \tag{4}
\end{equation*}
$$

As the concentration of the chromophore and its emission intensity $\left(I_{0}\right)$ are known, the value in saturation, $I_{\text {sat }}$, is calculated from the representation of $I v s$. [DNA].

According to the McGhee von Hippel model ${ }^{31}$ the concentration of the free probe in each sample ( $C_{\mathrm{F}}$ ) was calculated using eqn (5), where $C_{\mathrm{T}}$ is the total concentration of the probe and $P$ is the ratio of the observed fluorescence intensity of the bound probe to that of the free probe.

$$
\begin{equation*}
C_{\mathrm{F}}=C_{\mathrm{T}}\left(I / I_{0}-P\right) /(1-P) \tag{5}
\end{equation*}
$$

The value of $P$ is the $y$-intercept from the plot of $I / I_{0} v s$. $1 /[\mathrm{DNA}], I$ and $I_{0}$ are the fluorescence intensities of the probes in the presence or absence of DNA. The amount of bound probe $\left(C_{\mathrm{B}}\right)$ at any concentration is given by $C_{\mathrm{T}}-C_{\mathrm{F}}$. The binding constant $(K)$ and the binding site size ( $n$ ) in base pairs were obtained from the plot of $r / C_{\mathrm{F}} v s$. $r$, where $r=C_{\mathrm{B}} /[\mathrm{DNA}]$ using eqn (6).

$$
\begin{equation*}
r / C_{\mathrm{F}}=K(1-n r)[(1-n r) /[1-(n-1) r]]^{n-1} \tag{6}
\end{equation*}
$$

## Circular dichroism (CD) studies

The CD spectra were recorded at $24{ }^{\circ} \mathrm{C}$ on a Jasco J-720 spectropolarimeter with UV/Vis (200-700 nm) photomultiplier. Solutions of the probe and CT-DNA in Tris buffer were placed in a 1 cm (or 2 cm ) path-length quartz cell, and the spectra were recorded in the $200-650 \mathrm{~nm}$ region with subtraction of the buffer baseline. The following operating parameters were used to collect the CD spectra: bandwidth, 0.5 nm ; sensitivity, 10 mdeg ; resolution, 0.2 nm ; scan speed, $50 \mathrm{~nm} \mathrm{~min}^{-1}$; response time 4 s ; accumulations, 3.

## Linear dichroism (LD) studies

The LD measurements were performed with a Jasco J500 A spectropolarimeter that was equipped with an IBM PC and a Jasco J interface. The studies were done with CT-DNA in 10 mM phosphate buffer at pH 7.2 , and the sample orientation was produced by a device that was designed by Wada and Kozawa for the studies of differential flow dichroism of polymer solutions at a shear gradient of $700 \mathrm{rpm} .{ }^{32}$ The reduced linear dichroism, was defined by the ratio ( $\mathrm{LDr}=\mathrm{LD} / A_{\text {iso }}$ ) between the LD values and the absorbance of the unoriented sample at rest $\left(A_{\text {iso }}\right)$, which might be related to the orientation of DNA and the angle between the respective light-absorbing transition moment and DNA helix axis according to Norden et al. ${ }^{33}$

## Cell studies

Cell culture. B16F1 murine melanoma cells (ECACC, UK) were grown in DMEM containing GlutaMax I supplemented with $10 \%$ heat-inactivated fetal bovine serum and $1 \%$ penicillin/streptomycin antibiotic solution (all from Invitrogen). Cells were cultured in a humidified atmosphere of $95 \%$ air and $5 \% \mathrm{CO}_{2}$ at $37{ }^{\circ} \mathrm{C}$ (Heraeus, Germany), with the medium changed every other day.

## Fluorescence microscopy

B16F1 murine melanoma cells were cultured overnight on sterile coverslips, at $\sim 5 \times 10^{4}$ cells per well. The next day the medium was discarded and replaced by fresh medium containing the ligands ( $\mathbf{L} \mathbf{1}$ or $\mathbf{L} \mathbf{2}$ ) or complexes $(\mathbf{R e} \mathbf{1}$ or $\mathbf{R e} \mathbf{2})(70 \mu \mathrm{M})$ and cells were incubated for 3 h . After this loading, cells were washed with PBS and fixed for 20 min at room temperature with $3 \%$ paraformaldehyde in PBS. After 3 washings with PBS, cells on the coverslips were incubated in $5 \mu \mathrm{M}$ DAPI (4'-6-diamidino-2-phenylindol) (for $\mathbf{L 1}$ and Re1) or $5 \mu \mathrm{M}$ DRAQ5 (1,5-bis\{[2-(dimethylamino)ethyl]amino\}-4,8-dihydroxyanthracene-9,10-dione) (for $\mathbf{L 2}$ and $\mathbf{R e} 2$ ) for nuclear staining for 20 min at room temperature. After 3 more washings in PBS, the coverslips were mounted on standard microscope slides with glycerol $+3 \% N$-propyl gallate to improve the optical conditions and to prevent photobleaching. The samples were then imaged on a Leica DMRA2 upright microscope using a $100 \times$ 1.2NA objective and a Chroma +A4 UV filter for evaluating the fluorescence of DAPI ( $\lambda_{\mathrm{ex}} \max =359 \mathrm{~nm}$, $\lambda_{\mathrm{em}} \max =461 \mathrm{~nm}$ ) and L2 and Re2, a Y5 Cy5 filter for DRAQ5 ( $\lambda_{\mathrm{ex}} \max =647 \mathrm{~nm}, \lambda_{\mathrm{em}}$ $\max =670 \mathrm{~nm}$ ) and a L5 FITC filter for L1 and Re1. Images were acquired and colour-combined by using a CoolSNAP HQ 1.3 Mpixel-cooled CCD camera and the MetaMorph software.

## Confocal fluorescence microscopy

B16F1 murine melanoma cells were prepared as described above and incubated with L1 and Re1 $(70 \mu \mathrm{M})$ and $5 \mu \mathrm{M}$ DAPI solution for nuclear staining. After washing, the coverslips were mounted on standard microscope slides. The samples were then imaged on a Zeiss LSM 510 META inverted laser scanning confocal microscope using a $63 \times / 1.4$ Apochromat objective. The fluorescence of $\mathbf{L 1}$ and $\mathbf{R e} 1$ was detected using the 488 nm laser line of an Argon/2 laser and a BP 505-550 emission filter. DAPI fluorescence was detected using a 405 nm Diode laser and a BP 420-480 emission filter.

## Cellular internalization and retention

The cellular internalization assay was performed in B 16 F 1 murine melanoma cells seeded at a density of $2 \times 10^{5}$ cells per well in 24 well tissue culture plates and allowed to attach overnight. The cells were incubated at $37{ }^{\circ} \mathrm{C}$ for a period of 5 min to 24 h with about 200000 cpm of the complex in 0.5 mL of assay medium [MEM with $25 \mathrm{mM} N$-(2-hydroxyethyl)piperazine- $N^{\prime}$-ethanesulfonic acid and $0.2 \% \mathrm{BSA}$. Incubation was terminated by washing the cells with ice-cold assay medium. Cell-surface-bound radioligand was removed by two steps of acid wash ( 50 mM glycine $\cdot \mathrm{HCl} / 100 \mathrm{mM}$ $\mathrm{NaCl}, \mathrm{pH} 2.8$ ) at room temperature for 5 min . pH was neutralized with cold PBS with $0.2 \%$ BSA and, subsequently, the cells were lysed by a 10 min incubation with 1 N NaOH at $37{ }^{\circ} \mathrm{C}$ to determine the internalized radioligand. The cellular retention of the internalized radioconjugate was determined by incubating cells with the radiolabeled compound for 3 h at $37^{\circ} \mathrm{C}$, washing them with cold assay medium, removing the membrane-bound radioactivity with acid buffer wash and monitoring radioactivity release into the culture media $(0.5 \mathrm{ml})$ at $37{ }^{\circ} \mathrm{C}$. At different time points over a 4 h incubation period, the radioactivity in the medium and in the cells were separately collected and counted in a $\gamma$-counter. Cellular internalization and retention data was based on three determinations for each time point, and are expressed as an average plus the standard deviation.

## Nuclear internalization

B16F1 cells were seeded at a density of 0.2 million/well into 24well tissue culture plates and allowed to attach overnight. Cells were incubated in humidified $5 \% \mathrm{CO}_{2} / 95 \%$ air, $37^{\circ} \mathrm{C}$ for a period of $30 \mathrm{~min}, 1,2,3,4,5$ and 6 h with about 200000 cpm of radioconjugate in 0.5 mL of assay medium. After incubation cells were washed with PBS with $0.2 \%$ BSA ( $250 \mu \mathrm{l} /$ well) and removed from the plate with trypsin $(100 \mu \mathrm{l} /$ well $)$. The inactivation of trypsin was performed with $250 \mu 1$ of culture medium. The cells in suspension were centrifuged ( $800 \mathrm{rpm}, 2 \mathrm{~min}$ ) and washed twice with cold PBS with $0.2 \%$ BSA. Cells were lysed in $500 \mu \mathrm{l}$ of lysis buffer (Tris $10 \mathrm{mM}, \mathrm{MgCl}_{2} 1.5 \mathrm{mM}, \mathrm{NaCl} 140 \mathrm{mM}$, Nonidet P$400.02 \%$, pH 8.0-8.3). After 15 min of incubation in ice, the cell suspension was centrifuged at 1300 g at $4^{\circ} \mathrm{C}$ for 1 min . The activities of supernatant (activity outside the nucleus) and of the precipitate (activity retained in the nucleus) were measured (3 replicates) in a $\gamma$-counter for different incubation times.

## Plasmid DNA studies

DNA cleavage activity was evaluated by monitoring the conversion of supercoiled plasmid DNA (sc) to open circular DNA (oc) or linear DNA. Plasmid DNA (300 ng, pUC19) was incubated with complexes Re1 and Te1 for 48 h at room temperature in Tris ( $\mathrm{pH}=7.4$ ). After this time, $5 \mu \mathrm{~L}$ of DNA loading buffer was added and the samples were loaded onto a $0.8 \%$ agarose gel (AppliChem) in TBE $1 \times$ (Tris-borate-EDTA) buffer containing $15 \mu \mathrm{~L}$ of ethidium bromide ( $10 \mathrm{mg} \mathrm{mL}^{-1}$, AppliChem) for visualization of DNA. Controls of non-incubated and of linearized plasmid were included in both extremes of an 18-well gel plate. The electrophoresis was carried out for 18 h at 20 mV . Bands were visualised under UV light and photographed using an AlphaImager EP (Alpha Innotech). All samples in the figure were obtained from the same run. Peak areas were measured by densiometry using AlphaView Software from Alpha Innotech. Peak areas for the sc form were corrected using the factor 1.42 to account for its lower staining capacity by ethidium bromide ${ }^{34}$ and used to calculate the percentage of each form (sc and oc), and the ratio sc/oc.

## Acknowledgements

Teresa Esteves and Sofia Gama thank the FCT for a doctoral and postdoctoral research grants (SFRH/BD/29154/2006 and SFRH/BPD/29564/2006, respectively). COST Action D39 is also acknowledge. The QITMS instrument was acquired with the support of the Programa Nacional de Reequipamento Científico (Contract>REDE/1503/REM/2005-ITN) of Fundação para a Ciência e a Tecnologia and is part of RNEM - Rede Nacional de Espectrometria de Massa.
