

INFLUENCE OF PARTIAL ROOTZONE DRYING ON ASPECTS OF GRAPE AND WINE QUALITY

KEREN BINDON

School of Agriculture and Wine
The University of Adelaide

A thesis submitted to The University of Adelaide in fulfilment of the requirement for the degree Doctor of Philosophy

April 2004

TABLE OF CONTENTS

Chapter 1: General introduction	1
1.1 The definition of grape and wine quality	1
1.2 Secondary metabolites as an indicator of grape and wine quality	2
1.2.1 The phenols	4
1.2.2 The terpenes	7
1.3 The environmental regulation of grape secondary metabolites	9
1.3.1 A definition of water deficit	9
1.3.2 The concept of oxidative stress	10
1.3.3 Secondary metabolites as protectants against oxidative stress	12
1.3.4 The potential to manipulate secondary metabolism with deficit irrigation	14
1.4 Current research focus within the Australian wine industry	15
1.5 Aims and objectives within the current study	17
Chapter 2: General materials and methods	18
2.1 Field experiments	18
2.1.1 Nuriootpa Shiraz experiments	18
2.1.1.1 Shiraz PRD and pruning experiment	18
2.1.1.2 Shiraz canopy experiment	19
2.1.2 Langhorne Creek Cabernet Sauvignon experiment	20
2.1.3 Shading experiments on Shiraz and Cabernet Sauvignon	22
2.1.4 Fruit sampling procedure	24
2.2 Cabernet Sauvignon pot experiment	24
2.3 Mini-winemaking procedure	25
2.4 Statistical Analysis	27
Chapter 3: The effect of PRD on vine physiology, growth and yield components	28
3.1 Introduction	28
3.1.1 Irrigation of grapevines and the need for shoot vigour control	28
3.1.2 The introduction of Partial Rootzone Drying (PRD)	29
3.1.2.1 The concept of PRD	29
3.1.2.2 The effect of PRD on vine physiology	30
3.1.2.3 The effect of PRD on yield components	31
3.1.3 The combined effect of pruning and irrigation on vine growth and yield components	32
3.2 Materials and Methods	34
3.2.1 Experimental	34
3.2.2 Shoot growth rate	34
3.2.3 Gas exchange measurements	34
3.2.4 Leaf and Stem water potential	35
3.2.5 Pruning weight	35
3.2.6 Yield components	35
3.2.7 Soil water measurement	36
3.2.8 Canopy measurements of solar radiation	36
3.2.9. Statistical analysis	37

3.3 Results and Discussion	37
3.3.1 The effect of PRD on leaf gas exchange and water status	37
3.3.1.1 The Langhorne Creek Cabernet Sauvignon experiment	37
3.3.1.2 The Nuriootpa Shiraz experiment	43
3.3.2 Effect of PRD and node number on canopy growth and yield components	48
3.3.2.1 The Langhorne Creek Cabernet Sauvignon experiment	48
3.3.2.2 The Nuriootpa Shiraz experiment	51
3.3.3 The effect of PRD on light penetration within the vine canopy	58
3.4 Conclusions	63

Chapter 4: the effect of PRD on grape berry ripening **65**

4.1 Introduction	65
4.1.1 Primary metabolic processes associated with grape berry ripening	65
4.1.2 The effect of irrigation and berry microclimate on grape berry ripening	67
4.1.2.1 Irrigation	67
4.1.2.2 Bunch exposure and temperature	69
4.1.3 The effect of crop load on grape berry ripening	70
4.2 Materials and Methods:	71
4.2.1 Experimental	71
4.2.2 Determination of sugars, pH and titratable acidity (TA) in juice samples	71
4.2.3 Extraction and analysis of malic and tartaric acids	72
4.2.4 Determination of the inorganic ion content of berry tissue	72
4.3 Results and Discussion	73
4.3.1 The effect of PRD on grape berry ripening in Cabernet Sauvignon at Langhorne Creek	73
4.3.2 The effect of PRD on fruit acidity under shaded conditions	75
4.3.3 The effect of PRD and node number per vine on grape berry ripening in Shiraz at Nuriootpa	79
4.4 Conclusions	86

Chapter 5: The effect of PRD on grape berry and seed development **88**

5.1 Introduction:	88
5.1.1 The pattern of grape berry development	88
5.1.2 The effect of water deficit on berry size	89
5.1.3 The influence of the seed on grape berry development	90
5.1.4 Developmental changes occurring in the seed at veraison	91
5.1.5 The contribution of seed tannins in vinification	92
5.2 Materials and Methods:	94
5.2.1 Sample collection and processing	94
5.2.2 Seed tannin extraction	94
5.2.3 HPLC analysis of the seed tannin extract	95
5.3 Results and Discussion	96
5.3.1 Berry and seed development	96
5.3.2 Seasonal variation in the developmental profile of seed tannins	100

5.3.3	The effect of PRD on grape seed tannin composition	103
5.3.4	Hypothesis for seed tannin production under PRD irrigation	106
5.3.5	Seed tannin concentration in fruit and wine	109
5.4	Conclusions	111
Chapter 6: the concentration of anthocyanin and phenolics in grapes and wine – a question of berry size?		112
6.1	Introduction	112
6.1.1	Berry size as an indicator of fruit and wine colour	112
6.1.2	The effect of irrigation on anthocyanin concentration in fruit and wine	113
6.1.3	Factors contributing to wine colour	114
6.2	Materials and methods:	115
6.2.1	Experimental	115
6.2.2	Extraction of anthocyanins	116
6.2.3	Analysis of wine colour and phenolics	116
6.2.4	HPLC analysis of wines	117
6.2.5	Statistical analysis	118
6.3	Results and Discussion:	118
6.3.1	Effect of berry size and PRD irrigation on fruit anthocyanin and phenolic composition	118
6.3.1.1	Experiment 1: The effect of node number and PRD on anthocyanins and phenolics in Shiraz grapevines	119
6.3.1.2	Experiment 2: Effect of PRD on anthocyanins and phenolics in Cabernet Sauvignon	125
6.3.1.3	Experiment 3: Anthocyanin and phenolic concentration in berry skins of Cabernet Sauvignon	128
6.3.2	Effect of PRD on wine colour and phenolic composition	130
6.4	Conclusions	135
Chapter 7: The effect of PRD on anthocyanin composition and developmental profile		137
7.1	Introduction	137
7.1.1	Changes in anthocyanin composition during ripening	137
7.1.2	The effects of sunlight and temperature on anthocyanin concentration	139
7.1.3	The effect of bunch exposure on anthocyanin composition	140
7.1.4	The effects of PRD irrigation on anthocyanin composition	141
7.2	Materials and methods	143
7.2.1	Experimental	143
7.2.2	Extraction of anthocyanins	144
7.2.3	HPLC analysis of anthocyanins	144
7.3	Results and Discussion	146
7.3.1	Developmental changes in the anthocyanin profile of Cabernet Sauvignon fruit and wine with PRD (Experiment 1)	146
7.3.2	The effect of total shade on the anthocyanin profile of PRD-treated fruit (Experiments 2 and 3)	154
7.4	Conclusions	158

Chapter 8: Quantification of C₁₃-norisoprenoids in grapes and wine	159
8.1 Introduction	159
8.11 The C ₁₃ -norisoprenoids	159
8.12 The natural formation of C ₁₃ -norisoprenoids in grapes and wine	160
8.13 Quantification of specific C ₁₃ -norisoprenoids in grapes and wine	161
8.2 Materials and Methods	163
8.21 C ₁₃ -norisoprenoid standards	163
8.22 General headspace-SPME sampling procedure	163
8.23 Instrumental analysis	164
8.24 Quantitative analysis	164
8.3 Results and Discussion	165
8.31 Comparison of fibres	165
8.32 Adsorption rate of the standards	166
8.33 Linear calibration of standards and reproducibility	167
8.34 The effect of salt addition on the recovery of C ₁₃ -norisoprenoids in model wines	170
8.35 Extraction of C ₁₃ -norisoprenoids from grape homogenates	171
8.36 Rate of C ₁₃ -norisoprenoid hydrolysis	173
8.4 Conclusions	174
Chapter 9: Environmental aspects of C₁₃-norisoprenoid metabolism in the grape berry	175
9.1 Introduction	175
9.1.1 Developmental regulation of C ₁₃ -norisoprenoids	175
9.1.2 Light-exposure in the regulation of C ₁₃ -norisoprenoids and carotenoids	178
9.1.3 The effect of water stress on carotenoids and its implications for C ₁₃ -norisoprenoid concentration	180
9.2 Materials and Methods:	182
9.2.1 Experimental:	182
9.2.2 Extraction and HPLC analysis of carotenoids	184
9.2.3 Analysis of C ₁₃ -norisoprenoids	185
9.2.4 Statistical analysis	186
9.3 Results and discussion:	186
9.3.1 Experiment 1: Effect of total shade on the composition of carotenoids in fruit and C ₁₃ -norisoprenoids in fruit and wine (Nuriootpa Shiraz)	186
9.3.2 Experiment 2: Effect of canopy structure on the composition of C ₁₃ -norisoprenoids in fruit and wine	190
9.3.3 Experiment 3: Effect of irrigation (PRD) on the composition of carotenoids in fruit and C ₁₃ -norisoprenoids in fruit and wine of Cabernet Sauvignon at Langhorne Creek.	196
9.3.3.1 The effect of PRD on the carotenoids lutein and β-carotene	197
9.3.3.2 The effect of PRD on C ₁₃ -norisoprenoids	200
9.4 Conclusions	203

Chapter 10: General discussion and conclusions	205
10.1 How does PRD affect secondary metabolism in grape berries?	205
10.1.1 The contribution of berry size to the concentration of secondary metabolites	207
10.1.2 Bunch exposure	209
10.1.2.1 The response of grape berry anthocyanins to sunlight	209
10.1.2.3 The response of grape berry isoprenoids to sunlight	211
10.1.3 Hydraulic and/or non-hydraulic plant signalling	212
10.2 Yield versus quality – the limitations of the PRD technique	214
10.2.1 Irrigation cycling	214
10.2.2 Node number per vine	216
10.3 Relevance of the current findings to the wine industry	217
10.4 Suggestions for future research	218
Literature	220
Appendices	

ABSTRACT

The effect of partial rootzone drying (PRD) on the composition of grape and wine secondary metabolites was investigated. At harvest, total anthocyanin and phenolic concentration in fruit of *Vitis vinifera* L. cvs Shiraz and Cabernet Sauvignon was either unaltered or increased in response to PRD over two seasons. Where an increase in anthocyanin concentration was found with PRD, this was found to be independent of berry size. Rather, increases in anthocyanin concentration were most likely due to an increase in anthocyanin production in the berry skins. In Cabernet Sauvignon wine made from one vintage, total colour was enhanced by 10% in response to the PRD treatment, although in that season total anthocyanin concentration was unaltered in the fruit or wine.

This colour enhancement was due to an increase in coloured pigments in copigmented or polymeric form, that is in association with other anthocyanins or phenolic compounds. This is a significant finding, as it shows that the colour of wine is not dependent upon anthocyanin concentration alone, but rather on reactions taking place during winemaking and wine-ageing. The colour enhancement was found to be maintained after a year's ageing in the bottle. A key question which arises from this work is which component(s) of total phenolics in PRD-treated wines is responsible for this effect. Preliminary investigation of seed proanthocyanidins and flavan-3-ols showed that their content per berry was unaltered by the PRD treatment. However, where berry weight was decreased due to PRD, the concentration of these seed tannins was increased on a per gram basis. This could potentially lead to an increased contribution of seed tannins to total wine phenolics in PRD wines. The effect of this is two-fold. Firstly, seed tannins are known to be weak copigments and could in part account for the increased copigmentation and polymerisation of anthocyanins observed with PRD. Secondly, an increased concentration of seed tannins in PRD wines could alter wine astringency and mouthfeel properties.

In both fruit and wine samples, PRD was found to cause a decrease in the contribution malvidin-glucosides to total anthocyanins. Thus, levels of non-malvidin glucosides, namely delphinidin and cyanidin, were increased by PRD. This effect was investigated as fruit matured post-veraison, and was evident from early in berry development. Preliminary results indicate that this response requires the presence of high incident light levels to the fruit during development, but is not mediated by increased bunch exposure alone. Shading of fruit led to a significant decrease in all anthocyanin types, and caused a shift in the ratio of acetyl- and 3p-coumaryl-glucosides to mono-glucosides. The PRD treatment, however, did not cause changes in the proportions of acetyl-, 3p-coumaryl- and mono-glucoside anthocyanins. These results show that the response of the anthocyanin pathway to the PRD treatment is most likely mediated by physiological signals within the fruit and vine, rather than due to a change in bunch zone microclimate. An important class of potential flavour and aroma compounds in grapes are the C₁₃-norisoprenoids. As the precursors to these compounds are fruit-derived, rather than by-products of fermentation, the potential exists for their manipulation using viticultural practices. Previously, bunch exposure has been thought to be the primary factor mediating the final levels of C₁₃-norisoprenoids in fruit. The current study has shown that total shading of developing bunches using artificial means led to a significant decrease in the levels of these compounds in both fruit and wine samples of Shiraz. However, when fruit of this variety was subjected to natural changes in bunch exposure, resulting from alterations in canopy structure, the response of the C₁₃-norisoprenoids to these conditions was either small or insignificant. Of the three C₁₃-norisoprenoids studied, namely β-damascenone, β-ionone and TDN, only TDN showed a significant response to bunch exposure under these conditions.

Preliminary results of this study on Shiraz indicated that the concentration of the C₁₃-norisoprenoids β-damascenone and TDN can potentially be influenced by changes in vine shoot vigour and canopy architecture, induced by a water-deficit. This finding was validated by a study on Cabernet Sauvignon, where the effect of PRD on fruit C₁₃-norisoprenoids was investigated. The concentrations of the C₁₃-norisoprenoids β-damascenone, β-ionone and TDN were shown to be increased by up to 30% in response

to PRD in Cabernet Sauvignon fruit over two vintages. The changes in these compounds in the fruit were associated with increased levels of the carotenoids lutein and β -carotene, which are potential precursors to the C₁₃-norisoprenoids. The results of the current study have shown that the regulation of C₁₃-norisoprenoid concentration in grapes and wine may not be primarily due to the level of incident light on developing bunches, although the presence of light is necessary for their production. Rather, the effect of deficit irrigation practices on whole-vine physiology and vine shoot vigour holds stronger potential as a tool for the viticultural manipulation of these compounds in fruit and wine.
