ANTI-MOG ANTIBODIES ARE FREQUENTLY ASSOCIATED WITH STEROID-SENSITIVE RECURRENT OPTIC NEURITIS

OPEN

Optic neuritis (ON) is an inflammatory disease of the optic nerve characterized by pain and visual loss and often associated with multiple sclerosis (MS) or neuromyelitis optica spectrum disorders (NMOSD). Recent evidence suggests that certain forms of ON are associated with anti-myelin oligodendrocyte glycoprotein (MOG) antibodies.^{1–4}

A distinct clinical subset of ON is characterized by multiple episodes that involve one or both optic nerves, occur within months or weeks, and do not involve any other associated clinical or radiologic findings. This entity, defined as either recurrent optic neuritis (rON) or chronic relapsing inflammatory optic neuritis (CRION),⁵ is typically corticosteroid-responsive and corticosteroid-dependent, often requiring immunosuppressive therapy for corticosteroid-sparing effect.

Our aim was to determine whether aquaporin-4 (AQP4)-negative patients with ON harbor antibodies to MOG and whether anti-MOG antibodies are clinically relevant.

Methods. We examined sera from 111 patients initially referred to our diagnostic service for AQP4 testing. These patients had at least one episode of unilateral or bilateral ON, as reported by their referring physicians. All 111 patients were AQP4-negative. Twelve patients with primary progressive MS and 30 patients with relapsing-remitting MS (RRMS) were used as disease controls. The Ethics Committee of the University of Athens granted ethical approval.

Anti-MOG screening was performed using a cell-based-assay (CBA). Patient sera (1:60 dilution) were applied on live human embryonic kidney 293T cells and transiently transfected with full-length MOG enhanced green fluorescent protein followed by a goat anti-human secondary antibody (Alexa Fluor 568). Positive samples were retested and titrated in a blinded fashion by M.R.

To investigate optic nerve specificity, anti-MOG-positive sera were applied onto 10 μ m nonfixed or 2% paraformaldehyde-fixed sections of fresh frozen human optic nerves (Netherlands Brain Bank,

Amsterdam). A commercial monoclonal anti-MOG antibody was used as a positive control (Millipore, Billerica, MA; clone 8–18C5).

Results. Anti-MOG antibodies were detected by CBA in 8/111 AQP4-seronegative patients and in 0/42 MS disease controls (figure 1, B–D). All 8 MOG-positive patients had at least one episode of ON, and 5 of them fulfilled the criteria for rON/CRION (defined as ≥ 3 episodes of ON within a period of a few months to a year). Fifteen of 30 patients with RRMS had at least one episode of ON, and 10 of the 15 had a relapsing ON course.

The 5 patients with rON/CRION (followed by M.C.D. for 2–11 years) had recurrent disease confined to optic nerves, often associated with or preceded by pain. Brain/orbital MRI or CSF analyses were normal except for optic nerve enhancement in 2 patients. Spinal MRI depicted one small subclinical chronic lesion in the cervical spine in one of the patients who never developed any clinical symptoms of myelitis. Antibody titers did not correlate with disease severity or number of relapses (figure 1A). All received IV steroids during the early attacks, but they were subsequently maintained on a low-dose oral regimen. In 2 patients, the attacks occurred very frequently when the oral corticosteroid dose was lowered below 15–20 mg every other day, necessitating the concurrent administration of an immunosuppressant such as mycophenolate mofetil. One patient with multiple episodes over many years who eventually developed optic atrophy in one eye also received rituximab without success; relative stability (only 1 or 2 episodes yearly) was induced by bimonthly plasmapheresis (figure e-1 at Neurology.org/nn).

As human MOG antibodies do not recognize paraffin-fixed denatured epitopes,⁶ we used fresh-frozen, nonfixed, or lightly fixed human optic nerve tissue as substrate. No specific binding of the patients' sera or IgG was observed (figure e-2A).

Discussion. We have characterized and longitudinally followed up 5/8 patients with anti-MOG-positive rON/CRION without spinal cord or brain symptomatology. These patients do not fall within the rubric of NMOSD, and our follow-up revealed that relapses were confined to the optic nerves and were highly sensitive to even low doses of oral

Supplemental data at
Neurology.org/nn

Figure 1 Clinical characteristics and antibody profile of patients

A

Patient #	M/F	Age of first ON episode	Clinical features	Episodes of ON	Brain & spinal MRI	MOG titers	Treatment
1	M	46	rON, pain	≥3 in a year	Normal	1:320	Low-dose oral CS
2	M	41	rON, pain	2-12 in a year	Normal	1:320	Low-dose oral CS, mycophenolate mofetil, rituximab, PE
3	F	40	Bilateral rON, pain	≥3 in a year	Normal	1:160	Low-dose oral CS
4	F	43	ON, pain, nausea	No data	Normal	>1:640	Low-dose oral CS
5	F	21	Bilateral ON, pain	No data	C3-C4 lesion	>1:640	Low-dose oral CS, IVIg
6	F	37	Bilateral rON, pain	No data	Normal	1:160	Low-dose oral CS
7	F	20	rON, pain	2-7 in a year	Normal	>1:640	Low-dose oral CS, mycophenolate mofetil
8	F	42	rON, pain	≥3 in a year	Normal	1:160	Low-dose oral CS

(A) Clinical characteristics of myelin oligodendrocyte glycoprotein (MOG)-positive patients with recurrent optic neuritis (rON). (B–D) Cell-based assay of a representative patient. (B) MOG-enhanced green fluorescent protein (EGFP) transfected human embryonic kidney 293T cells. (C) Immunostaining with serum of a representative patient with rON on live non-permeabilized MOG-EGFP transfected cells. (D) Merged immunofluorescence image that shows colocalization. Scale bar = 100 μm. CS = corticosteroids; IVIg = IV immunoglobulin; ON = optic neuritis; PE = plasma exchange.

corticosteroids. Our results confirm recent observations^{3,4} that anti-MOG antibodies are frequently associated with recurrent forms of ON.

Anti-MOG antibodies have also been associated with pediatric inflammatory demyelinating diseases, including acute disseminated encephalomyelitis.⁷ A comparative epitope mapping of MOG antibodies from different syndromes identified a dominant MOG epitope but failed to elucidate a causative relationship or define distinct clinical phenotypes.⁶ No binding of patients' sera was observed in our optic nerve preparations, in which native epitopes are preserved. Whether the rON-associated anti-MOG antibodies are pathogenic, causing conduction block in the optic nerve, demyelination, or edema, remains unclear.

Our observations suggest that anti-MOG antibodies are frequently associated with the rON/CRION

phenotype, which is a highly steroid-responsive disorder. Although the rON series is small, the finding is supported by the observation that all of the RRMS control patients with ON were MOG-seronegative.
