Zirconolite: A Review of Localities Worldwide, and a Compilation of its Chemical Compositions

Abstract

A compilation of the chemical data and brief review of the mineral zirconolite, essentially CaZrTi207, is presented. A total of 321 chemical analyses, 169 previously unpublished, from 39 of the 46 known terrestrial localities, and covering IO rock types are tabulated. A brief description of the minerals associated with zirconolite is outlined for each locality. Data from all zirconolite-bearing lunar rocks have also been compiled. The recently published nomenclature scheme for zirconolite is employed throughout.

SYNOPSIS A compilation of the chemical data and brief review of the mineral zirconolite, essentially CaZrTi₂O₇, is presented. A total of 321 chemical analyses, 169 previously unpublished, from 39 of the 46 known terrestrial localities, and covering 10 rock types are tabulated. A brief description of the minerals associated with zirconolite is outlined for each locality. Data from all zirconolite-bearing lunar rocks have also been compiled. The recently published nomenclature scheme for zirconolite is employed throughout.

INTRODUCTION

Zirconolite, although a relatively rare accessory mineral, is found in a wide range of rock types and geological environments. To date, zirconolite has been reported from 46 terrestrial localities and from 13 lunar samples: it has not been reported in meteorites. The chemical composition of natural zirconolite can vary extensively, with the main substitutions involving rare earth elements, actinide elements, niobium and iron. Synthetic zirconolite is a major component in SYNROC, a synthetic polyphase titanate ceramic designed to immobilise high-level radioactive waste. In this paper, we compile and tabulate all reported chemical data for natural zirconolites, including new, and previously unpublished analyses: we group zirconolites into specific rock types or paragenetic types, and denote those samples that are stored in the collections of the Mineralogy Department, The Natural History Museum, London.

recently by Bayliss *et al.* (1989), who summarized the crystallographic and chemical characteristics of these minerals, detailed their historical documentation, and rationalized their nomenclature.

Under the Bayliss *et al.* (1989) IMA-approved nomenclature scheme, zirconolite is the non-crystalline (metamict) mineral, or the mineral with undetermined polytypoid of CaZrTi₂O₇; zirconolite-3O is the three-layered orthorhombic polytypoid of CaZrTi₂O₇; zirconolite-3T is the three layered trigonal polytypoid of CaZrTi₂O₇; zirconolite-2M is the two-layered monoclinic polytypoid, or aristotype (White, 1984) of

NOMENCLATURE

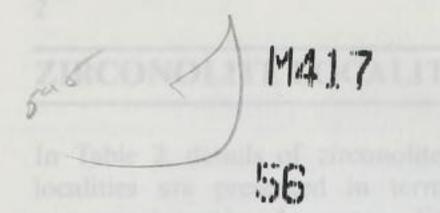

In the literature, several minerals with stoichiometries close to CaZrTi₂O₇, but with different crystal structures, have been reported and this has led to confusion in the nomenclature of these minerals. The compound CaZrTi₂O₇ can exist as three superstructures with monoclinic, orthorhombic and trigonal symmetries (Rossell, 1980), each being a polytype (White, 1984), subsequently redefined as polytypoids (Bayliss et al., 1989). However, the original type material, polymignite (Berzelius, 1824), zirkelite (Hussak & Prior, 1895) and zirconolite (Borodin et al., 1956) are metamict and their structures cannot be unambiguously defined. Further problems in identification and characterisation have arisen, in part because the frequent occurrence of actinide elements in the structure may render the mineral partially or totally metamict, and in part because the often small grain size does not allow for routine crystallographic techniques to be employed. These nomenclature problems have been addressed by Nickel & Mandarino (1987) and most

© The Natural History Museum, 1996

CaZrTi₂O₇; zirconolite is polymignite (metamict), and zirkelite is the cubic mineral with formula $(Ti,Ca,Zr)O_{2-x}$. Smith & Lumpkin (1993) have subsequently described two additional polytypes which appear to be supercells of the zirconolite-2M and 3T structures (zirconolite-4M and -6T, respectively).

CHEMICAL COMPOSITION

Zirconolite has five cation-acceptor sites, these being Ca in 8-coordination, Zr in 7-coordination, and three distinct Ti sites: Ti(I) and Ti(III) are both 6-coordinate, and Ti(II) is 5-coordinate (Gatehouse et al., 1981; Mazzi & Munno, 1983). In natural (and synthetic) zirconolites, a wide range of cation substitutions can occur (e.g. Ringwood, 1985), ranging in ionic size from 0.051nm (Ti⁴⁺) to 0.112nm (Ca²⁺) – ionic radii data from Shannon (1976) – and charge from 2+ (Mg) to 6+ (W). Predominant substitutions are: the rare earth elements including Y (REE) and actinide (ACT) elements for Ca: Hf for Zr; and Nb, Fe, Ta, Mg and W for Ti. In natural zirconolites the chemical variation is extensive; of the major components, CaO ranges from 1.83 to 16.54%, ZrO₂ from 22.82 to 44.18%, and TiO₂ from 13.56 to 44.91% (Table I). Up to 79% of the Ca site can be replaced by other cations (e.g. analyses A4, L11, Table 3). and up to 65% of the Ti site (analysis C69, Table 3).

DETAILS

from terrestrial and lunar of their host rock (or ganalysis numbers, together

with references relating both to the first report for that occurrence, and to the sources of the analytical data. Full chemical analyses, where available, are given in Table 3.

Kimberlite. Raber & Haggerty (1979) report zirconolite from three localities in South Africa. All their microprobe analyses are presented in Table 3 (K1 to K3); however, two analyses (K1 and K2) have significantly higher ZrO_2 values than all other zirconolites reported. The number of Zr cations for these analyses, recalculated on the basis of 7 oxygens, exceed the theoretical value by >50% and >100%. It seems probable therefore, that these analytical data are in error, or that the minerals analysed are not zirconolite. Calzirtite has been suggested as a possible alternative mineral for one of these questionable phases (Kogarko *et al.*, 1991). Analyses K1 and K2 are thus omitted from comparative data of zirconolites (such as in Table 1).

Zirconolite described by Raber & Haggerty (1979) is very fine-grained, associated with baddeleyite, \pm zircon, ilmenite, armalcolite and calcite, and is considered to have been formed as a secondary mineral due to infiltration of, and reaction with, a carbonatitic fluid.

Ultrabasic Rocks. Zirconolite has been described from two ultrabasic cumulate complexes – Laouni, Algeria (Lorand & Cottin, 1987) and Rhum, Scotland (Williams, 1978).

At Laouni zirconolite occurs as compositionally homogeneous, discrete grains up to 200µm in diameter, in plagioclase-rich adcumulates. Although baddeleyite also occurs in this intrusion, it is located in cumulates richer in trapped intercumulus liquid. Analyses U1–U2 (Table 3) are from Lorand & Cottin (1987). In the layered, ultrabasic complex of Rhum zirconolite occurs as a rare, late-stage accessory mineral, associated with apatite, baddeleyite and zircon, predominantly in olivine-rich mesocumulates – i.e. those cumulates with a relatively high proportion of trapped (and fractionated) magma. The microprobe analysis (U3, Table 3) is from Fowler & Williams (1986). Syenite. Zirconolite has been described from four syenite localities.

At Glen Dessarry, Scotland (Fowler & Williams, 1986), zirconolite occurs as an accessory mineral in a rock consisting of aegirine augite, edenitic amphibole, hypersolvus alkali-feldspar, orthoclase, albite and biotite. Zirconolite, typically <10µm in diameter, is enclosed by alkali feldspar phenocrysts and associated with Fe-Ti oxides, titanite, allanite, apatite and zircon. The microprobe analysis (S1, Table 3) is from Fowler & Williams (1986).

Zirconolite is reported in the alkaline intrusions of the Arbarastakh massif, Aldan, Russia, where segregations of zirconolite occur in [a] '... micatized large-grained pyroxenite ... ' with accessory apatite and ilmenite (Borodin *et al.*, 1960). In Table 3, analyses S2 (Borodin *et al.*, 1960) and S3 (Gaidukova *et al.*, 1962) are wet chemical determinations on mineral separates; analysis S4 (Wark *et al.*, 1973) is a microprobe analysis of a separate zirconolite grain.

Zirconolite (described as 'polymignite') was reported from the syenite pegmatites of Fredicksvärn, S. Norway by Berzelius (1824), and was a mineral separately analysed by Brögger (1890) using 'classical' wet chemical techniques (S5, Table 3). It also occurs at Langesundfjord, near Larvik in coarse-grained syenite pegmatites (S6 and S7, Table 3 – previously unpublished microprobe data).

Zirconolite (reported as 'polymignite') was described from a 'sanidinite' at Campi Flegrei, Italy (Mazzi & Munno, 1983). No analysis is included in Table 3, because the total of the reported analysis is low. Material is no longer available for analysis (Munno pers. comm., 1992).

Nepheline Syenite. At Pine Canyon, Utah, USA, zirconolite was found as an accessory mineral associated with hibonite, perovskite and pseudobrookite (Agrell et al., 1986). The rock-forming minerals include corundum, nepheline and Mg-hercynite. Analyses (NS1-NS6, Table 3) are previously unpublished wavelength-dispersive microprobe data (CTW). At the Elk Massif, Poland, zirconolite and Nb-zirconolite are reported in an association with apatite, fluorite and pyrochlore in agpaitic nepheline syenite pegmatites (Dziedzic, 1984). The major minerals of the pegmatites are microcline, nepheline, aegirine, arfvedsonite, and more rarely eudialyte. No analytical data are given for the zirconolite. At Chikala, Chilwa Alkaline Province, Malawi, zirconolite occurs also as an accessory mineral, up to 0.3mm in size, in a nepheline syenite (sample number BM1980, P23(1), Platt et al., 1987 - microprobe analyses NS7-NS11, Table 3). The rock-forming minerals are alkali feldspar, nepheline, biotite, apatite and an opaque oxide phase. At Tchivira, Angola, niobian zirconolite is reported as intimately crystallized with wöhlerite from nepheline syenite rocks of the alkaline complex (Mariano & Roeder, 1989). Analyses NS11 to NS16 are previously unpublished microprobe data of zirconolite-(Y) [see above] from Tchivira.

Gabbro Pegmatite. Harding et al. (1982, 1984) describe accessory zirconolite (reported as 'zirkelite'), with acicular habit, from a gabbro pegmatite of Tertiary age at St. Kilda, Scotland. The pegmatite consists essentially of ferroaugite, ferroedenite, chlorite, magnetite, Mn-rich ilmenite, quartz and alkali feldspar. Associated with zirconolite are the accessory minerals biotite, epidote, allanite, titanite, apatite and zircon. The pegmatite is considered to have formed from the last residues of basaltic (tholeiitic) liquid from which the major Mg-minerals and feldspars of the Glen Bay Gabbro had previously precipitated.

The zirconolite analysis tabulated here (G1, Table 3) is from Fowler & Williams (1986). Harding *et al.*'s (1982) original analysis totals only 91%, as it excludes many of the heavy REE, Hf and Ta.

Since the ΣREE^{3+} exceeds 50% of the Ca site cations, it is *sensu strictu* a rare earth mineral, and following the Bayliss & Levinson (1988) nomenclature guidelines, this mineral can be classified as **zirconolite-(Y)** [subject to approval from the CNMMN].

At Pilanesberg, Transvaal, South Africa (Lurie, 1986), zirconolite occurs as an accessory mineral (A.N. Mariano, personal communication, 1993). No analytical data is reported.

At Tre Croci, near Vetralla in the Vico Volcanic complex of the Roman Comagmatic Province, Latium, Italy, crystalline epitaxial zirconolite occurs as an accessory mineral associated with baddeleyite, zircon and rare thorian hellandite in a sanidinitic ejectum with nepheline and sodalite (G.C. Parodi, personal communication, 1993). Analyses NS17 to NS21 are previously unpublished microprobe data from this locality.

Carbonatite. Carbonatites, with sixteen reported occurrences of zirconolite, seem to be the most common host rock type for this mineral. In the Kola Peninsula, Russia, zirconolite occurs in four separate carbonatite complexes where detailed descriptions, including studies on crystal morphology and crystal chemistry, is given in Bulakh & Ivanikov (1984).

In the Afrikanda complex, Kola, zirconolite is described from the amphibolitized and fenitized pyroxenites (Borodin *et al.*, 1956) In Table 3 analyses C1–C3 are wet chemical analyses; C1–C2 from Borodin *et al.* (1956) and C3 from Bulakh *et al.* (1960). C4 is a microprobe analysis (Wark *et al.*, 1973).

At Vuoriyarvi, Kola, zirconolite was first described as zirkelite (Bulakh *et al.*, 1960), then '... tentatively described as a niobium variety, niobozirconolite' (Borodin *et al.*, 1960). It is associated with apatite-magnetite rocks (accompanying carbonatites, Zhuravleva *et al.*, 1976), accumulating predominantly in apatite, and was also observed replacing hatchettolite (Kapustin, 1980). Analyses C5–C7 (Table 3) are unpublished wavelength-dispersive microprobe data (CTW) on separate grains (BM1970,39); C8–C11 are wet chemical analyses: C8–C9 from Borodin *et al.* (1960), C8 and C11 quoted in Kapustin (1980); C10 is from Bulakh *et al.* (1960).

Bulakh et al. (1960) refer to zirconolite from the Sayan Province, Russia. Analysis C12 (Table 3) is a wet chemical analysis from Bulakh et al. (1960).

At Seblyavr, Kola, niobozirconolite was initially identified as zirkelite (Bulakh *et al.*, 1960) and is described as '... the typical mineral of the process of amphibolization-dolomitization confined to carbonatite ... ' (Kapustin, 1980). The mineral is partly metamict, it has good symmetry habit and displays complicated twinning (Bulakh *et al.*, 1960). Associated minerals are apatite, clinohumite, tetraferriphlogopite, pyrrhotite and richterite. Analysis C13 (Table 3) is a wet chemical analysis from Bulakh *et al.* (1960). are unpublished microprobe data (from Bochon University) from Prof. G. Bayer.

At Sokli, Finland, zirconolite (reported as zirkelite) was originally described by Vartiainen (1980) from hydrothermal phoscorites. The crystals have apparently formed '... at the expense of pyrochlore and occur around and as inclusions in pyrochlore ...', and are also found as separate prisms. Analyses C67–C70 (Table 3) are unpublished wavelength-dispersive microprobe data from Dr. I. Hornig-Kjarsgaard (pers. comm., 1992), analysed at the University of Mainz.

At Kaiserstuhl, Germany, zirconolite occurs with calzirtite, baddeleyite, Nb-perovskite and pyrochlore (Keller, 1984). Analyses C71 and C72 are wavelength-dispersive microprobe analyses (Keller, 1984; Sinclair & Eggleton, 1982).

In the Hegau volcanic province, Germany, zirconolite (described as 'Nb-zirconolite') is a typical accessory mineral in the carbonatitic tuffs (Keller *et al.*, 1990). Analyses C73–C88 (Table 3), are unpublished wavelength-dispersive microprobe analyses (CTW) of eight grains from a heavy mineral separate provided by Prof. J. Keller (Freiburg).

At Prairie Lake, Ontario, Canada, niobian zirconolite is reported in association with wöhlerite, pyrochlore, betafite and niobian perovskite (Mariano & Roeder, 1989). A microprobe analysis provided by Dr A.N. Mariano of six major elements is shown in Table 3 (C89).

At the Cummins Range Carbonatite, Kimberley Area, Western Australia, accessory zirconolite occurs in an apatite-amphibolite rock. Qualitative analysis of the zirconolite showed the presence of Ca, Zr, Ti and minor Fe, but with Nb absent (Dr. A.N. Mariano, personal communication, 1993).

At Howard Creek, British Columbia, Canada (Woolley, 1987; p.16), zirconolite is associated with zircon, magnetite and diopside in an apatite calcite carbonatite (Dr. A.N. Mariano, personal communication, 1993). There is no analytical data.

At Kovdor, Kola, zirconolite is associated with zones of carbonatization, Kapustin (1980). C14–C16 (Table 3) are wet chemical analyses: C14–C15 from Kapustin (1980), and C16 from Kukharenko *et al.* (1965). Analyses C17–C34 are unpublished wavelength-dispersive micropobe data (CTW), on chemically-zoned zirconolite grains in a thin section of carbonatite. Associated minerals are baddeleyite and U-Ta-rich pyrochlore (Williams, in press).

At Schryburt Lake, Ontario, Canada, zirconolite occurs intergrown with calzirtite, baddeleyite, and U-rich pyrochlore (Williams & Platt, in preparation). Microprobe analyses (C35–C58, Table 3), show significant variations in ΣREE_2O_3 and Nb₂O₅. Some of the grains have $\Sigma REE^{3+} > 50\%$ of the Ca site, and, with Nd as the most abundant REE, this mineral can be classified as **zirconolite-(Nd)**, following Bayliss & Levinson (1988), and subject to approval from the CNMMN.

At Santiago Island, Cape Verde Republic, non-metamict **zirconolite-2M** occasionally up to 2mm in diameter, occurs as an accessory mineral, often associated with pyrochlore, in apatite-rich sövite, beforsite and glimmerite rocks of the Canafistula carbonatitic plug (Silva, 1979; Silva & Figueiredo, 1980). Analysis C59 (Table 3) is the wavelength-dispersive microprobe analysis from Silva & Figueiredo (1980).

At Phalaborwa, South Africa, zirconolite was first described by Verwoerd (1986) from the carbonatite. Analyses C60–C64 (Table 3) are unpublished wavelength-dispersive microprobe analyses by CTW on sample BM1988,260, kindly provided by Prof. G. Bayer (ETH, Zürich). In this rock, zirconolite is associated with baddeleyite and zircon, the latter mineral probably having crystallized at a later stage. Analyses C65–C66

At Catalao, Goias, Brazil (Woolley, 1987; p.179), zirconolite is associated with apatite and phlogopite in a calcite carbonatite (Dr. A.N. Mariano, personal communication, 1993). There is no analytical data.

At Araxá, Minas Gerais, Brazil (Woolley, 1987; p.66), zirconolite occurs as prismatic crystals with anastase in a glimmerite, and also with pyrochlore, baddeleyite and apatite in a calcite carbonatite (Dr. A.N. Mariano, personal communication, 1993). There is no analytical data.

Metasomatic Rocks. Zirconolite has been reported from metasomatic rocks at nine localities, although analyses from only seven of these have been published.

In the Mt. Melbourne Volcanic Field, Victoria Land, Antarctica, zirconolite occurs as isolated grains with a maximum grain diameter of 0.08mm within ultra-potassic veins in a mantle xenolith from a basanite host (Hornig & Wörner, 1991). The major vein-forming minerals are leucite, plagioclase, nepheline, Mg-ilmenite, apatite and titaniferous mica. Analyses M1-M7 (Table 3) are selected from Hornig & Wörner (1991) as being the least 'contaminated' by adjacent silicate minerals.

At the contact between granodiorite with gneisses and marbles in the Bergell aureole, Switzerland/Italy, chemically discontinuously-zoned zirconolite is observed, typically 30–40µm in diameter, associated with allanite and titanite, in a skarn (Gieré, 1986; Williams & Gieré, 1988). The major minerals of the skarn are calcite, spinel, phlogopite and anorthite. The microprobe analyses M8–M22 (Table 3) are unpublished data (CTW) of eleven grains from three discrete zones, the averages of which are published in Williams & Gieré (1988).

within Oetztal-Stubai complex, Austria, the In polymetamorphic metacarbonates, zirconolite and baddeleyite occur in several mineral assemblages consisting of chlorite, ilmenite, apatite, spinel, phlogopite, titanian clinohumite, olivine, calcite, dolomite and diopside (Purtscheller & Tessadri, Analyses M23-M27 (Table 3) are the 1985). wavelength-dispersive microprobe analyses by given Purtscheller & Tessadri (1985).

Adamello Italy, the contact aureole, In compositionally-zoned and corroded zirconolite occurs in two zones within a Ti-rich vein in dolomite marbles at the contact with a tonalite intrusion (Gieré, 1990a). In the phlogopite zone, zirconolite is always found associated with phlogopite and calcite (±dolomite), and occasionally with geikelite, rutile and fluorapatite. In the titanian clinohumite zone, zirconolite occurs with titanian clinohumite, spinel, calcite, dolomite, pyrrhotite, geikelite, fluorapatite and minor secondary chlorite. A detailed mineralogical and chemical description is given in Gieré & Williams (1992), and analyses M28-M66 (Table 3) are wavelength-dispersive microprobe analyses from Gieré (1990b).

At Koberg Mine, Bergslagen, Sweden, yttrian zirconolite occurs as anhedral grains, predominantly 20-30µm in diameter, in an altered phlogopite-rich sample associated with a marble skarn (Zakrzewski *et al.*, 1992). The low analytical totals (analyses M67-M94, Table 3) suggest the zirconolite is hydrated (Zakrzewski *et al.*, 1992).

At the agpaitic alkaline syenite complex of Lovozero, Kola, zirconolite (reported as 'zirkelite') has been described in a mineral assemblage including rosenbuschite, from the contact metasomatic rocks of the massif (Semenov *et al.*, 1963). Analyses M95-M96 (Table 3) are the wet chemical data of Semenov *et al.* (1963).

In a dolomitic marble from the Neichi mine, Iwate Prefecture, Japan zirconolite is associated with geikelite and baddeleyite, forsterite and spinel (Kato & Matsubara, 1991). The composition of zirconolite is close to the theoretical composition (analyses M97-M98, Table 3, from Kato & Matsubara (1991). At Sør Rondane, Antarctica, Grew et al. (1989) report zirconolite (qualitative analysis only, cf. p. 119) from a marble affected by metasomatic processes which had introduced rare metals. Associated minerals include dissakisite-(Ce) (Grew et al., 1991), calcite, dolomite, phlogopite, chlorite, ilmenite-geikelite and spinel. Rekharskiy & Rekharskaya (1969) discovered zirconolite (reported as zirkelite) intergrown with jordisite and abundant metasomatic pyrite, as veins in zones of altered trachytic to rhyolitic volcanic rocks. Locality details are not reported. Kinny & Dawson (1992) report the occurrence of zirconolite, as a rare accessory phase associated with zircon and baddeleyite, in a veined and metasomatised harzburgite xenolith from Kimberley, southern Africa. The metasomatism is MARID-related (Kinny & Dawson, 1992) and considered to be associated with kimberlite magma. Analysis M99, Table 3, is the unpublished mean of 6 microprobe analyses (Prof. J.B. Dawson, pers. comm., 1993). Rubin et al. (1993) report zirconolite occurring as inclusions in phlogopite in one sample of a complex skarn from the Ertsberg District of Irian Jaya, Indonesia. No analytical details are given.

new mineral 'zirkelite'), is found with baddeleyite and perovskite in the heavy mineral fraction from pyroxene sands of '... the decomposed magnetite-pyroxenite of Jacupiranga ...' (Hussak, 1895; Hussak & Prior, 1895; see also Pudovkina *et al.*, 1974). Analyses P1, P2 are unpublished wavelength-dispersive microprobe analyses (CTW) of separate grains (80142). The wet chemical analysis given in Hussak & Prior (1895) is not included here, as the chemical separation techniques employed in the analysis could only provide qualitative data for ZrO₂ and TiO₂.

In Sri Lanka, zirconolite (reported as 'zirkelite') was observed from two 'gem gravel' localities in the Sabaragamuwa Province: at Walaweduwa in the Bambarabotuwa district, and in southern Sabaragamuwa (Blake & Smith, 1913). Analyses P3, P4 (Table 3) are from Bambarabotuwa, and P5-P7 from Sabaragamuwa; analyses P8, P9 are microprobe data from Lumpkin *et al.* (1986); analysis P10 is an unpublished (CTW) wavelength-dispersive microprobe analysis of several grains (BM1905, 361).

'Other' Rock Types. Sapphirine Granulite: Zirconolite occurs as acicular grains in a mineral assemblage including sapphirine, spinel, enstatite and minor phlogopite from a sapphirine granulite nodule sampled from a xenolith-rich norite wall zone in the Archaean Vestfold Hills, east Antarctica (Harley, 1994). The zirconolite is considered to have been a relatively early crystallising phase during the melt crystallisation history of the entrapped granulite xenolith. Analyses SG1-SG3 (Table 3) are from Harley (1994).

Alnöite: Thin $(1 \ \mu m)$ rims of zirconolite (no compositional details given) are reported as overgrowing a baddeleyite crystal from the île Bizard alnöite, Québec, Canada (Heaman & Le Cheminant, 1993). Although the baddeleyite crystals are considered to be mantle-derived xenocrysts, the associated overgrowths, which include perovskite and melilite as well as zirconolite, are considered to have formed after exposure to the alnöite magma.

Placer Deposit. Zirconolite is reported as millimetre-sized crystals from two placer deposits.

At Jacupiranga, Sao Paulo, Brazil, zirconolite (named as the

Lunar. Zirconolite has been observed in several lunar samples, (*cf.* review by Frondel, 1975). Data from the literature are presented as analyses L1-L13 (Table 3). It occurs in coarse-grained basalts (Apollo 11, 15 and 17), in a feldspathic

(*) type POLYMIGNITE (**) type ZIRCONOLITE (***) type ZIRKELITE

now all renamed as zirconolite (see Bayliss et al., 1989)

(+) In BMNH collection

(1) Heavy mineral fraction from pyroxene sand; (2) Heavy mineral fraction from alluvial deposits: two separate localities; (3) Analysis from Hussak & Prior (1895) not included as method used could not adequately distinguish Ti from Zr.

peridotite (Apollo 12), in lithic fragments (Apollo 14, LUNA 20), and in a metamorphosed breccia (Apollo 16). Zirconolite is often associated with baddeleyite as small discrete crystals, no larger than 50µm in diameter, and is considered to have crystallised at a late stage from interstitial liquids in the lunar basalts (e.g. Busche *et al.*, 1972).

Lunar zirconolites are generally rich in Y and heavy-REE when compared with terrestrial zirconolites (Lovering & Wark, 1974; Kochemasov, 1980; Fowler & Williams, 1986). The majority of the lunar zirconolites have $\Sigma REE^{3+} > 50\%$ of the Ca site, and with Y being the dominant REE, these may be considered as **zirconolite-(Y)**.

DISCUSSION AND CONCLUSION

Zirconolite occurs as an accessory mineral only, generally less than 0.1mm in diameter, but from a wide variety of rock types. Its small size and low modal abundance means that it can be easily overlooked using traditional optical microscopy. However, with the increasing accessibility of analytical scanning electron microscopes (usually with a backscatter electron detector attached), zirconolite, even if present at a very low modal abundance, will be readily observed, because its backscatter component is considerably higher than the majority of the rock-forming minerals. It is probable therefore, that the number of zirconolite occurrences will increase significantly in the near future.

It is also evident that zirconolite is often zoned, and/or finely intergrown with other minerals, and early bulk chemical analyses were unable to characterise fully the chemical variability of this mineral. Microprobe analyses, together with a detailed SEM investigation, is therefore essential in any study. It is generally recommended that microprobe analysis is performed using wavelength-dispersive means, because zirconolite can accommodate more than 30 elements at the 0.1 to 1.0 wt.% concentration level (which in energy-dispersive electron microprobe analysis is close to, or below, the detection limit), However, quantitative analysis of sub-micron zones has been successfully undertaken using an energy-dispersive analytical transmission electron microscope (Lumpkin et al., 1994). As can be seen from the data for natural zirconolite, the range of elements substituting, and the degree of substitution are extensive. The most commonly occurring elements, and therefore the minimum that should be reported in any microprobe analysis of zirconolite are: Mg, Al, Si, Ca, Ti, Mn, Fe, Y, Zr, Nb, Hf, Ta, W, Pb, Th, U and of the REE, La, Ce, Pr, Nd, Sm, Gd. It should also be noted that Cr and Zn are present in some zirconolites: Cr predominantly from lunar samples, and Zn occasionally from metasomatic samples (e.g. Zakrzewski et al., 1992). H₂O has been reported in wet chemical analyses of separated grains (e.g. Borodin et al., 1960; Bulakh et al., 1960), and has also been inferred from low analytical totals of microprobe data (e.g. Platt et al., 1987; Zakrzewski et al., 1992). Na and K, although also quoted in some wet chemical analyses of separated grains, have not been observed in microprobe analyses. It is probable therefore, that Na and K are not present to any significant extent in zirconolite. It is of note also, that Sr and Ba generally do not occur in natural zirconolite, and Pb only rarely does so. These elements might have been expected to substitute more readily for Ca, but it appears that the Ca

structural site does not easily accommodate 2+ cations larger than Ca. The valency state of Fe in zirconolite is unclear: where measured directly on mineral separates, both FeO and Fe₂O₃ are present.

It is evident that zirconolite, although invariably occurring only as an accessory or 'trace' mineral in a range of rock types, is able to accommodate many incompatible elements, such as REE, ACT, Nb, Zr, Hf, Ta to concentration levels whereby it can become a major repository for these elements. As such, it has the for playing a significant role potential in the petrological/geochemical evolution of those rock-types in which it crystallizes. Several studies have provided evidence that zirconolite can reflect changes in the composition of the fluid during its evolutionary history, both in metasomatic systems (Williams & Gieré, 1988; Gieré & Williams, 1992), and in magmatic fractionation processes (Platt et al., 1987).

It is hoped that this review and compilation will prove useful as a comparative database for geologists who discover zirconolite in their samples, and also to material scientists working on various SYNROC projects, in order that they can compare laboratory-based experiments on synthetic zirconolite with studies of the natural forms of zirconolite.

This database is available in a computerised format from CTW. We would be grateful also to receive any additional analytical data and/or material from new occurrences of zirconolite, in order to periodically update this database.

ACKNOWLEDGEMENTS. We are very grateful to Professor G. Bayer (ETH, Zürich) for providing us with zirconolite samples from Phalaborwa, and also for some unpublished data, to Alf Olav Larsen (Porgrunn, Norway) for samples from Langesundfjord, to Dr. S.L. Harvey Edinburgh, Scotland for providing information on zirconolite from East Antarctica, to Professor J. Keller (Freiburg, Germany) for permission to analyse zirconolite from Hegau, to Dr I. Hornig-Kjarsgaard (University of Mainz, Germany) for allowing us to include her unpublished data from Sokli, to Professor J.B. Dawson (Edinburgh, Scotland) for unpublished data, to Dr E.S. Grew (University of Maine, USA) for providing material from Sør Rondane, Antartica, to Dr. A.N. Mariano (Carlisle, Massachusetts, USA) for providing samples and information on several zirconolite localities, and for some unpublished data, to Dr G.C. Parodi (University of Rome, Italy) for samples from Latium, Italy, and to the Kovdor Mining Museum, Kola Peninsula for material from Kovdor. We further wish to thank Drs M. Welch, A.R. Woolley and R.F. Symes and other colleagues at The Natural History Museum, London, also to Professor Andrei Bulakh (University of St. Petersburg) for comments and suggestions which have improved the manuscript, and to Greg Lumpkin (ANSTO, Australia) for discussions regarding synthetic zirconolite. This study forms part of a British/Swiss Joint Research Programme, and we gratefully acknowledge funding provided by the Schweizerischer Nationalfonds and the British Council (Grant No. 83BC-033381).
