Abstract

IODP Expedition 345 aimed to drill lower crust gabbros at Hess deep rift (East Pacific Rise, 2°14'N-101°30'W), which is located near the junction between EPR and the Cocos, Nazca and Ridge. Lower crust oceanic gabbros were sampled on a about 200 m wide bench located on the intrarift southern slope between 4675 and 4850 m below sea level, and total of 11 holes (1415A to P) were drilled, among which two reached a depth over 110 m below seafloor (Holes 1415J and 1415P; see IODP Expedition 345 Scientific Report, 2013). Primitive troctolites and olivine-rich gabbros were the main lithologies recovered from these two holes. Shipboard data showed a whole rock chemistry with a high Mg# in concordance with their primitive nature. In a MOR system, olivine is a typical primitive mineral and orthoyroxene (Opx) usually appear late in the crystallization sequence, when the magma already reached a significant degree of differentiation. In spite Opx is not expected in any primitive lithology, this mineral is commonly present in Hole 1415P gabbros and associated with olivine. This curious association of cumulate Opx with olivine and other primitive minerals was also observed at a lower extent in some gabbros from IODP Hole 1256D, in the upper Hess Deep crustal section (ODP Hole 894G)

We studied about 70 samples from Holes J and P, and 15 samples from the upper crust (ODP Hole 894G and rubbles from IODP site 1415) for their petrography and mineral chemistry. All samples are olivine gabbros and show an overall cumulate texture with ophitic to subophitic domain consisting of large clinopyroxenes enclosing plagioclase and olivine chadacrysts. Olivine is subhedral to sub-rounded and plagioclase appear as subhedral laths. Beside the main constituent phases in Olivine gabbros, a relatively high content of orthopyroxenes may be observed (≥ 5%). Three types of Opx textures may be distinguished in Opx-bearing olivine gabbros (1) recrystallized corona around olivine, (2)

exsolution within clinopyroxene and (3) large prismatic or poikilitic grains. The third type is the most common and overall texture points to a crystallization order starting with olivine and plagioclase, and finishing with clinopyroxene and then orthopyroxene.

In the upper crust, samples are less rich in olivine and mineral chemistry points to relatively differentiated characteristics compatible with a formation by fractional crystallization from a magma a MORB melt having undergone a certain degree of differentiation. In the lower crust, mineral chemistry show systematically primitive characteristics with high olivine forsterite content, clinopyroxene and orthopyroxene Mg# for all samples. Hole J gabbros show a clear evolution from the bottom to the top, with decreasing Mg# and increasing minor and trace elements contents in mafic minerals. Processes dominated by fractional crystallization can explain the genesis of the Hole 1415J gabbroic column. On the other hand, the narrow down hole variation ranges for Mg# in Opx (84-86%), Cpx (86-92%) and olivine (85-90%) in Hole 1415P, together with a a large scatter in minor and trace elements (Ti, Al, Cr, Ni, Mn, Yb, Cs, Zr, etc.), in Cpx and Opx suggests that, at a global scale, the gabbro column were only affected by a moderate degree of differentiation and melt/rock reaction leading to Mg/Fe ratio buffering played a major role in the formation process. However the relatively low Mg# (below 88%) values show that the reactant was rich in relatively differentiated mafic minerals with a general Mg# lower than in mantle rocks. Chemical zoning observed in the ophitic clinopyroxenes show that the crystallization process might be locally dominated by small-scale differentiation.

Calculated compositions for liquids in equilibrium with Cpx and plagioclase, using both minor and trace elements are consistently between the EPR MORB and the Galapagos basalts chemical domains. In contrast, the melt in equilibrium with Opx in Hole P plot out of the MORB and OIB domain and is significantly richer in Ti. Mg# calculations on all the

ferro-magnesian minerals show that Opx and olivine are in equilibrium while Cpx has a higher Mg# than the calculated Cpx in equilibrium with Opx These demonstrate that a two phases magmatic process occurred, in association with the melting of a enriched mantle source (similar to that producing enriched basalts at the Galapagos hotspot) to generate EPR lower gabbros: 1) Crystallization of a Mg/Fe ration buffered mush. The melt in this mush originated from an enriched mantle source, melts injected in the mush got buffered by a probable melt-rock reaction process occurring in the underlying troctolites. A certain degree of differentiation may occur in the mantle and troctolites, leading to stronger enrichment but the buffering event erased any chemical evidence of differentiation. The appearances of Opx at an early stage in the crystallization sequence suggest a Si-rich source compatible with pyroxenite melting. 2) Local differentiation leading to the crystallization of zoned Cpx in concurrence with Opx precipitation.

MORB melts crystallizing in Hole 1415J are expelled out from the lower crust to the melt lens located at the top of the gabbro section. Enriched melts crystallizing in Hole 1415P are not observed in the basalts formed at the top of the section, this show that some melts produced in the mantle were not extracted from the basaltic mush to the melt lens. They entirely crystallized in the lower crust and are not expressed at the surface. Our study showed the limitation of the basaltic glasses method, sued up to now in order to calculate a general MORB or enriched mantle source.

Chapter 1

1. Introduction:

1.1 General motivation and scope:

The Two third of the earth surface is recovered by oceanic crust, most of it formed at fast-spreading ridge. Moreover, more than 65% of the magmatic activity on Earth and probably the largest part of hydrothermal processes take place at a spreading ridge, making ocean ridge the main center of heat and chemical transfer between the geosphere and the hydrosphere. The high amount of energy expressed at spreading ridges is also believed to have been the main energy source accounting for life birth. Despite being the place of such important processes, spreading centers functioning is still mostly unknown. From decades, scientists are eager to understand the formation process of the oceanic crust taking place at ocean ridges, which includes partial melting of a given mantle source, magma migration, crystallisation and mixing, and interaction with hydrothermal fluids. But due to poor accessibility, important information are still missing.

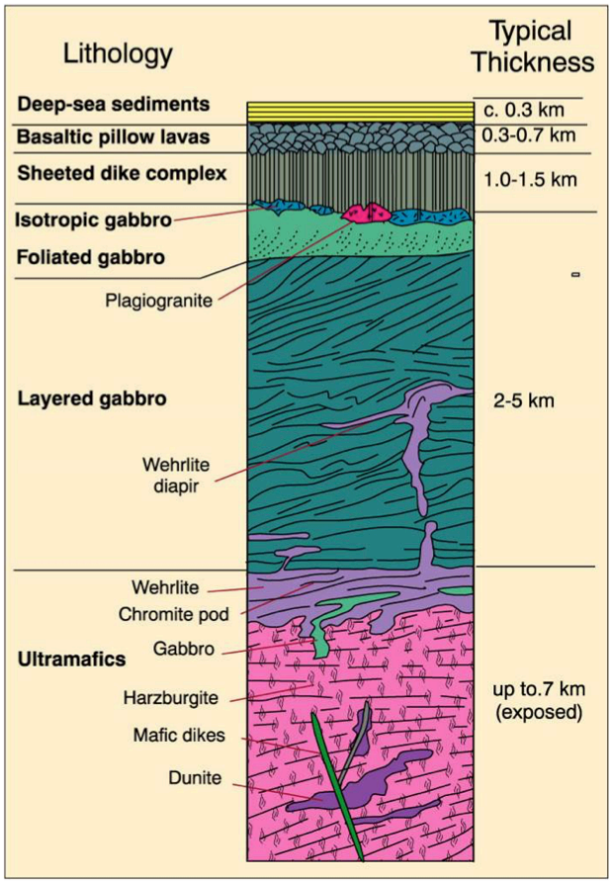

Figure 1.1: Ophiolite succession and seismic layers of oceanic (Boudier and Nicolas, 1985)

Ophiolite's Penrose model (Boudier and Nicolas,1985) (Figure 1.1) is the classical view of oceanic lithosphere layers and is believed to be representative of fast spread oceanic crust. Direct observations from Ophiolite give us some information about the lower oceanic crust and lithospheric mantle but their tectonic context of formation is always debatable (Gillis et al., 2013).

The process associated with mid ocean ridge basalt (MORB) generation involve magma migration to the base of the crust and passing through a lower crustal filter on their ascent to the upper. Most studies regarding crust genesis and ridge functioning at EPR focused on basalt and dolerite glasses and directly interpreted the results in terms of mantle source, neglecting the possible effect of fractional crystallization and other processes occurring within the thick gabbroic layer (the thickest in the oceanic crust section) (Coogan et al., 2007). Ignoring the complex processes leading to the formation of lower crustal rocks is partly due to difficult access (below several kilometers of water and mostly several hundreds of meters of basaltic rocks), but also to the difficulty to interpret crystalline rocks and magmatic chamber processes. The main consequence of this approach is that the effects of melt modification during the crystallization in lower crustal rocks, and thus on the resulting basaltic melt, are not clear.

In this context, ocean-drilling programs, i.e. DSDP and the following Ocean Drilling Program and Integrated Ocean Drilling Program, has provided deep access to lower crustal litho-units in various oceanic core complex (ODP 147 and IODP 345 reports). The surface of young ocean crust is mostly made of pillow basalts and old ocean crust is covered with a thick layer of deep marine sediments, so the access to the gabbroic crust is possible at only very specific tectonic contexts, such as transform fault or ocean lithosphere rifting where tectonic movements brought lower sections of the crust and sometime the lithospheric mantle up to the seafloor (ODP 147 report). In the vicinities of East Pacific Rise (EPR) Pito Deep and Hess Deep (Fig. 1.2) are examples of such tectonic window to

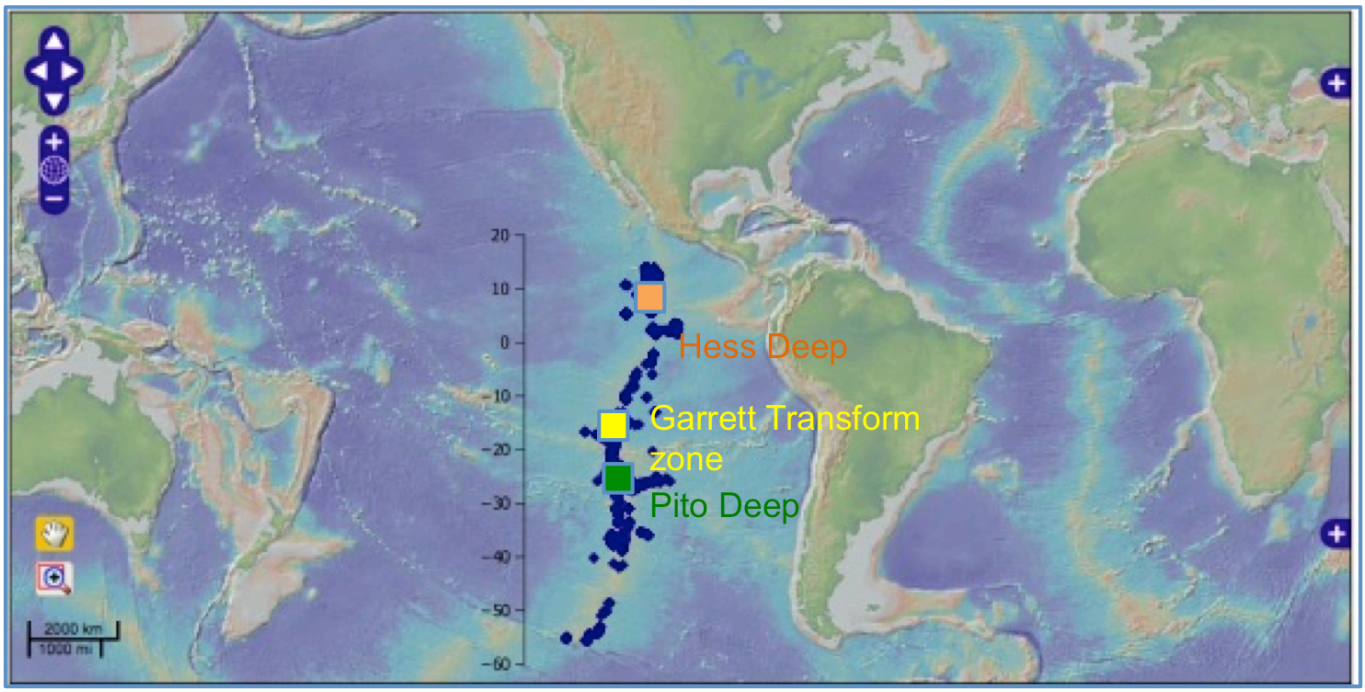

Figure 1.2: Map of East pacific rise, showing sampling point of lower crustal rock in Hess Deep, Garrett transform zone and Pito Deep. All the blue points are shown basaltic lithologies (PetDB)

the oceanic lower crust and mantle (Perk et al., 2007). At Hess Deep, the eastward propagation of Cocos-Nazca rift toward eastern flank of EPR causes the rifting which exposed lower crustal gabbroic and mantle lithology (ODP 147 and IODP 345 reports)

For at least the last 20Ma, the EPR opening rate has been the same as the Cocos-Nazca ridge propagation rate, leading to a steady state rifting uncovering deep crustal and mantle rocks at the tip of the propagator in the 20Ma old EPR lithosphere. Two drilling expeditions (ODP Leg. 147 and IODP Exp. 345) were performed at Hess Deep to recover gabbroic and mantle rocks (Natland and Dick, 1996), and several drilling and diving expedition allowed previous researchers to observe the total section of plutonic layers (Dick and Natland, 1996),. During Leg 147, the main recovered lithologies were, differentiated gabbronorites, olivine gabbros, oxide gabbros, basaltic dikes and also shallow mantle rocks (dunite, harzburgite with intercalated troctolite and olivine gabbro)

interpreted as lying close to petrological Moho (ODP 147 scientific report). The second expedition, IODP Expedition 345, was done in 2013 and aimed to recover young Lower crustal rock generated at fast spreading ridge, in order to establish a crustal accretion model in comparison with geophysical data (Gillis et al., 2013). Olivine gabbro and troctolites were the main sampled lithologies, with unexpected abundance of orthopyroxene in olivine gabbro (IODP Expedition 345 scientific report, 2013).

In this study, the petrology of lower oceanic gabbros in relation with their chemistry has been established by examining orthopyroxene rich gabbroic lithologies and some associated rocks. The present work coupled with previous study provide a complete understanding the processes involved in the formation of lower crustal rock at the fast-spreading EPR.

1.2. Previous studies:

1.2.1. Basalt petrogenesis: Mantle source

Previous studies were mainly focused on the volcanic, tectonic, hydrothermal activity of the ridge segments of oceanic crust (e.g. Allan et al 1996, Stern et al, 2011; Gillis et al; 2003 Arai, 2007). Geochemical studies of basalt reflects a wide range of composition that was interpreted in terms of different degrees of partial melting and total water contained in the mantle (which may control the extent of melting). For example, dolerite samples from the ocean drilling programs (DSDP, ODP, IODP) reflect high Mg# (>0.7), which was interpreted as representing highly primitive picritic basalt crystallizing from a melt with Mg# >0.73 (Allan et al., 1996). Their extremely depleted nature in LREE was directly linked to extremely depleted mantle source (Allan et al., 1996). On the other hand, the diversity of isotopic ratios and wide range of trace element concentrations observed in the basalts and dolerites sampled at EPR were interpreted to be the direct expression of a heterogeneous mantle source. Hofmann and White (1982) suggested that oceanic

lithosphere recycled in the mantle after subduction can be at the origin of the mantle heterogeneity. To characterize the original parental melt composition of basalt, the use of melt inclusions hosted in plagioclase and olivine phenocrysts is widely accepted (Zhang et al., 2012). The lack of variation among melt inclusions and their host crystal in N-MORB lava are interpreted in terms of extensive fractionation and mixing in the upper mantle. Finally, the correlations of the major element contents in phenocrysts with isotopic ratios were portrayed to be the result of a mixed pyroxenite-peridotite source (Zhang et al, 2012).

1.2.2. Evolution of EPR Upper gabbro:

Upper crustal gabbros are exposed along the northern escarpment and at the summit of the western end of the intrarift ridge. The northern scarp exposures, which directly underlie the sheeted dike complex, are dominated by gabbronorite, with lesser amounts of Fe-Ti oxide and amphibole gabbro, varitextured gabbro, olivine gabbronorite, Fe-Ti oxide gabbronorite, and rare tonalite (Hanna, 2004; Kirchner and Gillis, 2012; Natland and Dick, 1996). This gabbros have a wide range in Mg# (mean Mg# = 0.56; range = 0.30–0.76), with gabbronorite being the most primitive and Fe-Ti oxide ± amphibole gabbro being the most evolved end-members (Hanna, 2004; Kirchner and Gillis, 2012; Natland and Dick, 1996). The lithologies exposed at the summit of the western end of the intrarift ridge are similar to the Northern Escarpment, with gabbronorite, oxide gabbronorite, gabbro, olivine gabbro, and patches of pegmatitic amphibole gabbro (Gillis et al., 1993; Hékinian et al., 1993).

Plutonic rocks exposed along the central and eastern region of the southern slope of the intrarift ridge, between 4400 and 5400 mbsl, include gabbros, gabbronorites, olivine gabbros, and lesser trocolites that are, on average, more primitive than the summit of the intrarift ridge (mean Mg# = 0.71; range = 0.39–0.85) (Blum, 1991; MacLeod, unpubl. data, 2009). As with the gabbros, modal layering has not been documented for the deeper

gabbros. It is important to note that the stratigraphic depth of these more primitive gabbros is not known, as these rocks likely migrated downslope by mass wasting processes.

Hydrothermal fluid flow throughout the entire gabbroic sequence was dominated by pervasive fluid flow along grain boundaries, microfractures, and fractures. The shallow-level gabbros and the limited suite of gabbros show that incipient flow occurred at amphibolite facies (average temperature = 720°C) conditions and is manifest by amphibole veins that display no preferred orientation (Manning et al., 1996; Coogan et al., 2002a) and replacement of pyroxene by amphibole-dominated assemblages (Früh-Green et al., 1996; Gillis, 1995; Kirchner and Gillis, 2012). Whole-rock samples unaffected by a lower temperature stage of brittle deformation are depleted in δ 18O relative to fresh values (Agrinier et al., 1995; Lécuyer and Reynard, 1996) and show minor enrichment in 87Sr/86Sr (Lécuyer and Grau, 1996; Kirchner and Gillis, 2012). Calculated fluid/rock ratios using both isotopic systems range from 0.1 to 1 (Lécuyer and Grau, 1996; Kirchner and Gillis, 2012). The rate of cooling of the shallow-level gabbros is rapid (1,000 to 60,000°C/m.y.) and comparable to the upper gabbro section in the Oman ophiolite (Coogan et al., 2007; Faak et al., 2011).

Effects of Cocos-Nazca rifting reported in the gabbros which are exposed along the intraridge rift cooled to ~450°C, they became influenced by the creating a dense array of east–west tensile fractures filled with greenschist to zeolite facies assemblages and local cataclasis cemented with the same assemblage (Früh-Green et al., 1996; Manning and MacLeod, 1996).

1.2.3. Evolution of EPR Lower gabbro and relation with present work:

All previous work focused on the petrogenesis of the lower crust, in any context (fast or slow spreading rate, mid-ocean ridges, supra-subduction zones or ophiolites) showed that the genesis of gabbro is dominated by extremely complicated processes involving melt-

rock reaction with the upper mantle or partially crystallized mushes at the bottom of the crust, mixing of magma fractions with ambiguously different histories, fractional and non-equilibrium crystallization, etc. (Lissenberg et al 2013, Dourin et al, 2010). All these processes are likely to fractionate the trace elements and to consequently change the composition of their parental magma. Moreover, there is a strong contradiction between using the Penrose model as representative of fast to super-fast spreading ridge (Korenga and Kelemen, 1997) and neglecting the effect of gabbro genesis in the history of basaltic glasses.

Mantle peridotites are exposed in the vicinity of Site 895, southeast of Site 894. Clinopyroxene-poor harzburgites, at the most depleted end of the range for abyssal peridotites, are interpreted to be the residues of melting of a normal (N)-type MORB source (Natland and Dick, 1996). The association of dunite–troctolite-olivine gabbro with depleted harzburgite records the interaction of migrating melt with depleted harzburgite wall rock in the shallowest mantle (Natland and Dick, 1996; Arai and Matsukage, 1996; Arai et al., 1997).

Study with the lower crustal gabbros explain the formation which is always involve complicated processes that potentially have very strong influence on the composition of the magma emitted at MOR context and that gabbros should not be neglected in a general ridge model starting from mantle melting and going to basaltic magma quench at the top of the section. We report the results of petrographical and geochemical evolution of lower crustal gabbros from East Pacific Rise (EPR) recovered from Hess Deep rift. Enriched Major and trace elements evolution within the lower crustal gabbros suggests fractional crystallization along with the signature of Galapagos plume magma type malt discernible beneath EPR MORB system. Hess Deep basalts seem to be of purely MORB (Batiza et al, 1992) nature without any chemical evidence of enrichment. The lower crustal gabbroic rocks represent the main incompatible element reservoir, may act as a chemical filter by

preventing contamining primitive melts from the Galapagos hot spot to be expelled out of lower levels magmatic mushed.

1.3. Aims and structure of this thesis:

In the doctoral curriculum, I have been working with the genesis of lower crustal primitive gabbroic rocks that formed at the fast-spreading East Pacific Rise (EPR), are exposed at the Hess Deep Rift and that was sampled during Integrated Ocean Drilling Program (IODP) Expedition 345 (Gillis et al., 2013). Olivine gabbro and troctolite are the dominant plutonic rock types recovered. These rocks exhibit cumulate textures similar to ones found in layered mafic intrusions and some ophiolite complexes. A very significant first-order observation from this expedition is that orthopyroxene (Opx) was found as abundant phase in many of the layered primitive gabbroic rocks. Opx presents as interstitial and prismatic phase. Prismatic phase of opx coexisting with clinopyroxene (Cpx) in olivine gabbros and as monomineralic bands in primitive gabbros. This was unexpected, since experiments on the liquid line of descent of MORB show that opx always crystallizes late in the sequence of MORB-type systems, i.e. after the crystallization of olivine (Ol), plagioclase (Plg) and cpx.

Main objective of the research are as follows:

i) To demonstrate the origin of opx crystallization as well as cpx and other cumulates in primitive gabbro.

ii) Understanding the magmatic processes within deep oceanic crusts particularly in the fast spreading oceanic crust

iii) And ultimately the petrogenesis of oceanic gabbros and relationship between petrology and geochemistry of lower crustal rocks.

To achieve the goals of the research, following methods are performed:

i) Detailed petrographic study from thin section of gabbroic samples

ii) Modal analysis using pixel-counting method by ImageJ software

iii) Electron microprobe analysis of all the minerals and associated phases.

iv) La-ICPMS analysis of major phases (particularly core of the minerals)

Chapter 2

2. Geological context

2.1. Hess Deep:

Hess deep rift is the deepest part in a region near 2°14'N-101°30'W, i.e., north of Galapagos triple junction at the intersection of Cocos, Nazca and Pacific plates (Fig. 2.1) (Hey et al., 1972, 1977; Holdenand Dietz, 1972). The north south–trending EPR is spreading at 130 mm/y, and the east west–trending Cocos-Nazca Rift is propagating westwards toward the EPR at a rate of 42 mm/y, located 30 km from EPR axis, with 8km, wide 25km long. Studies indicate that the current configuration of the Galapagos triple junction has been active for at least 10 m.y. (Smith et al., 2011). The spreading of the EPR lead to initiate Galapagos microplate at ~1.5 Ma. Continued spreading created rifted structure bounded by a depression with depths of more than 5000 m, known as Hess Deep. It consists of oceanic lithosphere created on the axis of the fast spreading East Pacific Rise that was exposed during crustal uplift and faulting. The westward-propagating oceanic rift valley that is opening up the eastern flank of the equatorial EPR in advance of the westward-propagating Cocos-Nazca spreading center (Lonsdale, 1988). Hess Deep represent approximately 0.5Ma, East-West EPR crust exposed by two 5km wide east-west grabens which are further join to the east and deepens to >5400m below sea level (Gillis et al, 2013). Eastern end of the Cocos-Nazca spreading center initiate to building volcanic ridge, which is less significant in westward propagating ridge. Northern wall of Hess deep, called intrarift, which is less than 3000m deep and shallowest part of EPR. Northern and southern escarpments are rise to a depth of less than 2200m and the eastward rough and smooth side (Galapagos gore) indicating the eastern boundary. The uplifted intrarift exposed the lower crustal

rock as well as the upper mantle peridotite (Hekinian et al; 2014) to the western end and its southern slope.

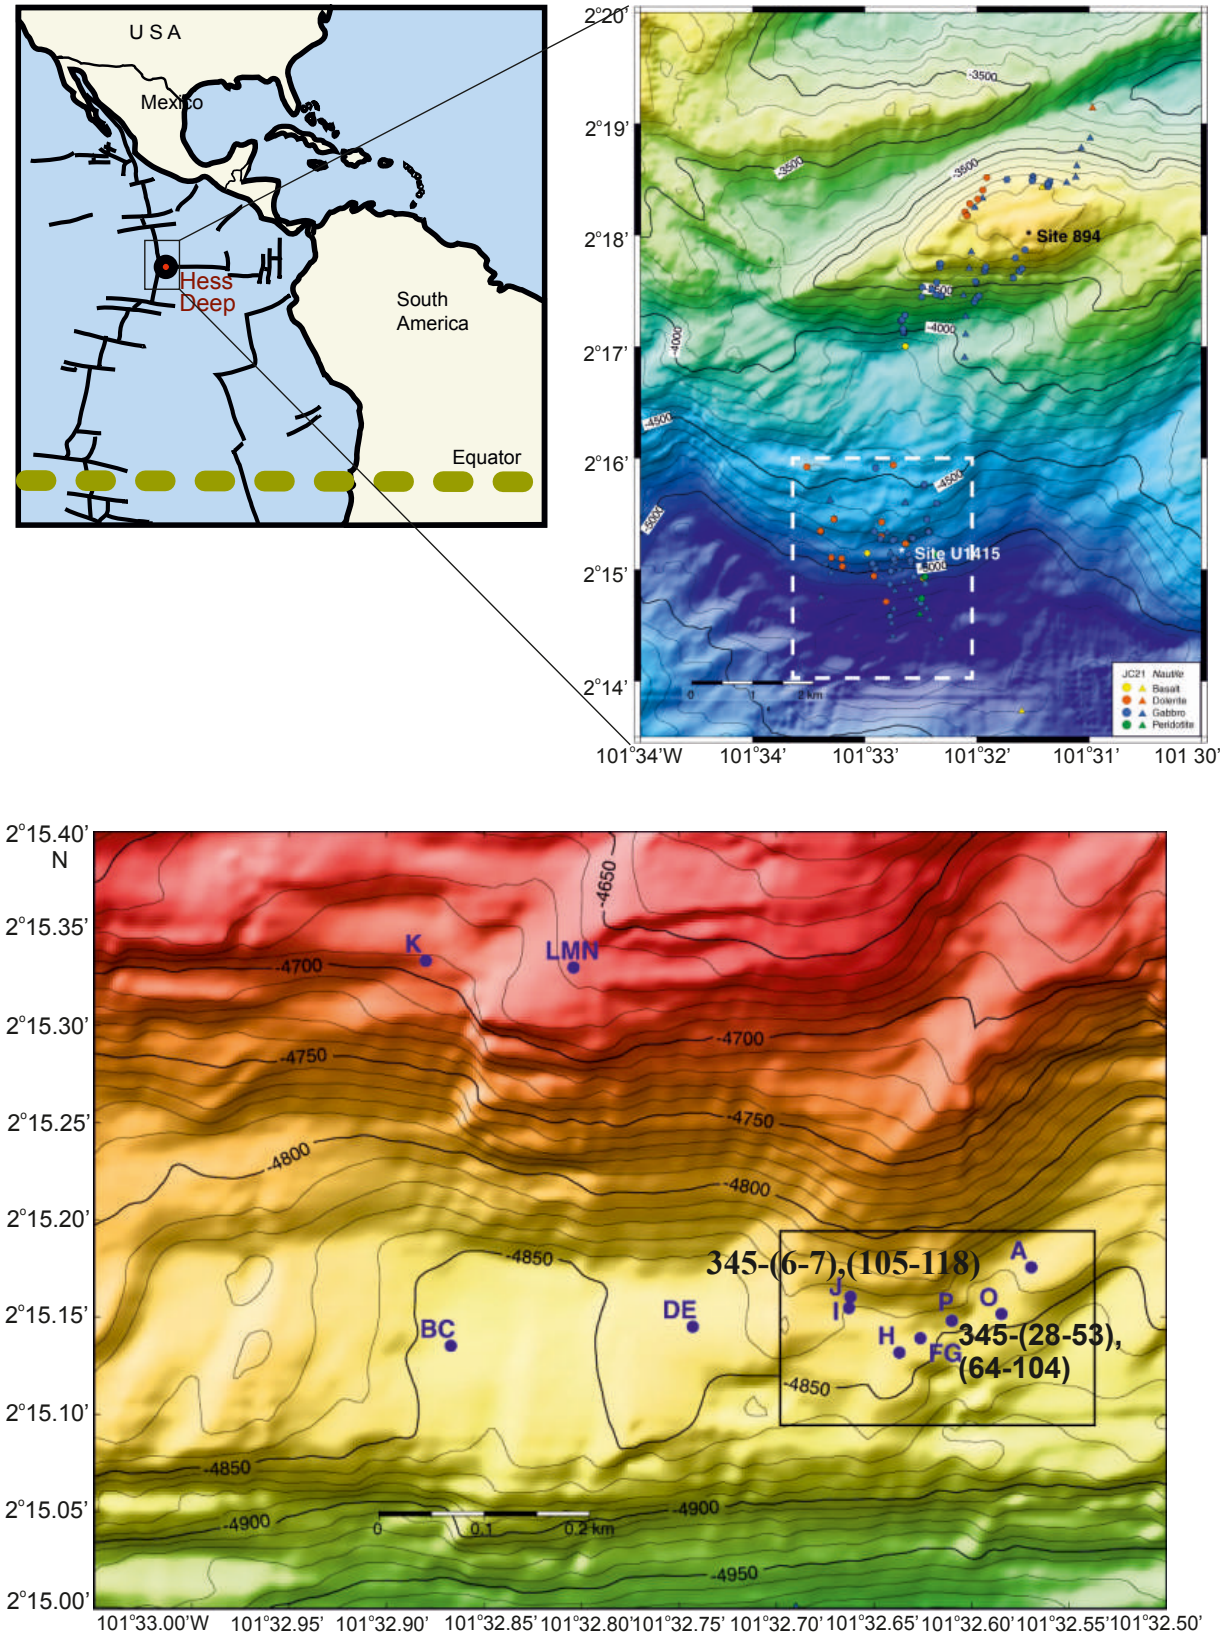

Figure 2.1: Map showing the area of Hess Deep in Equitorial Pacific. Bathymetric map showing the location of sampling in ODP 147 (Site 894) and IODP Expedition 345 (Site 1415) (Figure modified from IODP preliminary report, 2013)

2.2. IODP Expedition 147 site overview:

The principal objective of Leg 147 in 1992, was the recovery of continuous sections of crustal gabbroic rocks and shallow mantle harzburgite, dunite, and intercalated gabbroic rocks from the Hess Deep (ODP 147 report). The cored crustal sections at Site 894 were generated at the fast-spreading East Pacific Rise (EPR), approximately 1 Ma (Fig. 2.1). The exposures cored at Sites 894 (2°18.0'N, 101o31.5'W) and 895 (2°16.7'N, 101°26.7'W) were located on the crest and southern slope of an intra-rift ridge, respectively. At Site 894, 219.9 m was cored in seven holes, recovering 58.5 m of gabbroic rocks, principally gabbronorite with lesser amounts of gabbros, olivine gabbros and gabbronorites, oxide gabbros and gabbronorites, and basaltic dikes. Operations at Site 895 recovered shallow mantle rocks, interpreted as lying close to the petrological Moho, from six holes that penetrated a total of 272.9 m and recovered 64.56 m of rock. The rocks recovered were predominantly dunite and harzburgite, with intercalated, less abundant gabbro, olivine gabbro, and troctolite. In this study we are mainly concentrating on the samples recovered from site 894.

The objective of drilling at Site 894 was to sample a section of oceanic gabbros created at a fast-spreading center, by starting a hole directly on gabbros exposed at the top of the ridge. Six camera surveys were conducted at this site, covering a total area of 1.0 by 1.2 km, and seven sites were selected for test drilling to locate appropriate rock types and optimal drilling conditions.

Shallow holes were drilled on the flat, slightly sedimented summit of the ridge (Holes 894A, 894D, 894E), and on ledges close to the southern edge of the summit (Holes 894B, 894F). An attempt to start Hole 894C with a guide base failed. A second guide base was successfully deployed to start Hole 894G, close to test Hole 894F. A total of 219.9 m was cored, with a recovery of 58.5 m (26.6%). The gabbros occur in the upper parts of the section, and gabbronorites first appear at 45 mbsf. The plutonic rocks are non-layered,

show textural variations from ophitic to equigranular, and grain-size variations from fine to coarse (Natland and Dick, 1996). Some of the textural variability is related to the presence of patches, pockets, and veins of more coarse-grained gabbronorite hosted in finer grained gabbros and gabbronorites. Zircon and apatite are abundant in many of these coarser grained pockets (ODP 147 report).

2.3. IODP Expedition 345 site overview:

Taking advantage of such rare accessibility of lower crustal rocks, IODP Expedition 345 was sampled primitive lithologies from troctolite to varitextured-layered gabbros. Site U1415 is located along the southern slope of the intrarift ridge between 4675 and 4850 mbsl (Fig. 2.1). A series of 16 holes were drilled at Site U1415, two ~110 m below seafloor (mbsf) reentry holes (U1415J and U1415P), five single-bit holes (U1415E and U1415G–U1415I), two failed reentry holes (U1415K and U1415M), and six holes in which jet-in tests were conducted to assess sediment thickness (Holes U1415A–U1415D, U1415F, and U1415L) (Fig. 2.1)Site U1415 is centered on a ~200 m wide, flat-lying east-west–trending bench at 4850 mbsf that is covered with approximately <10–30 m of largely gabbroic rubbles overlain by a few meters of pelagic sediment mixed with lithic debris. Holes U1415E–U1415J are in an area where primitive gabbroic rocks were recovered. Holes U1415K–U1315N are situated along a ~100 m wide, flat-lying shoulder at ~4675 mbsl, ~160 m shallower than the bench, where slightly more evolved gabbroic rocks were recovered during the JC21 site survey. Among these 16 holes Hole P and Hole J has special significance as they recovered highest mass of lower crustal rocks with highest depth i.e more than ~50 mt thick core samples. The scale of the blocks can be assessed in the two deepest holes, U1415J and U1415P, situated ~110m apart.

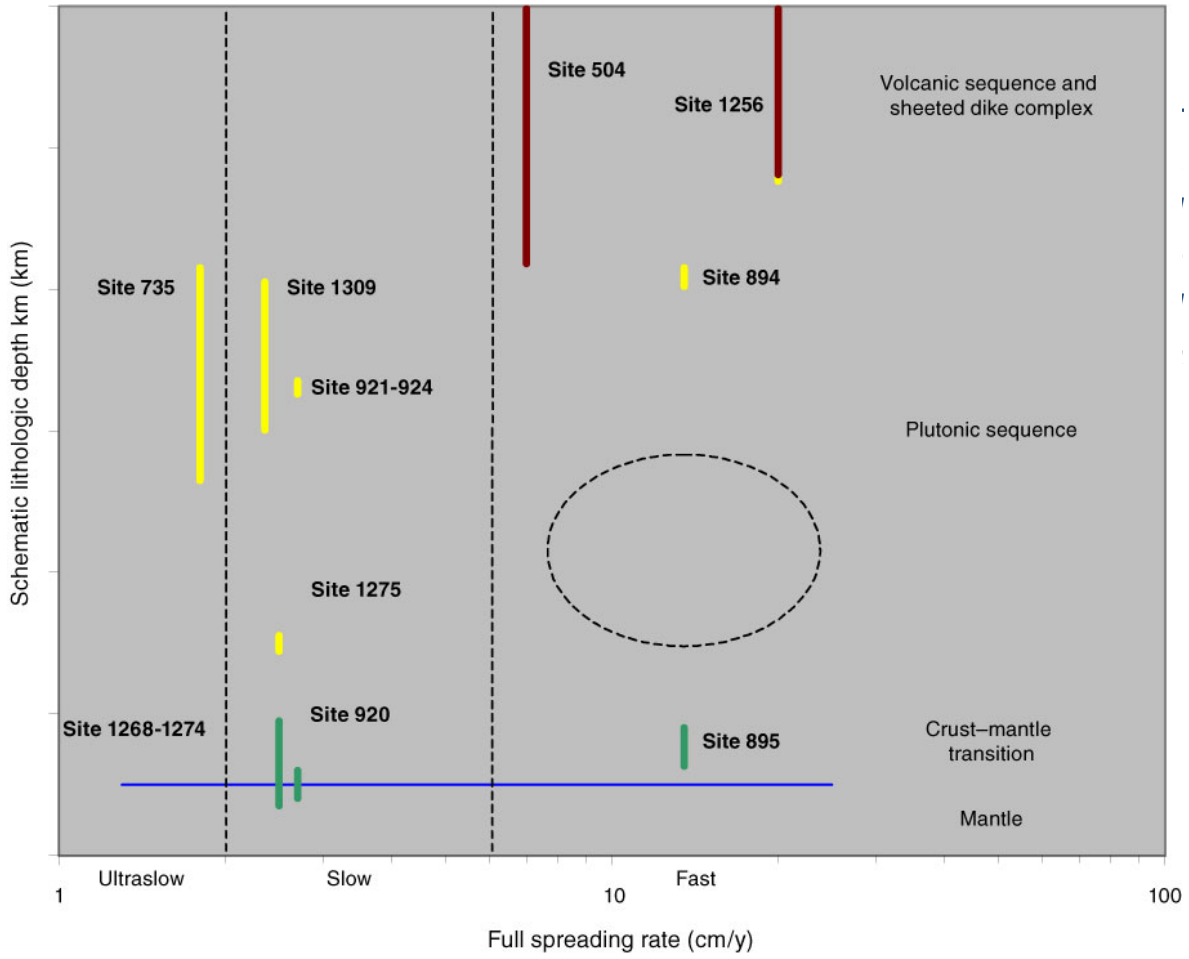

Figure 2.2: Schematic diagram of existing basement holes that have major penetrations into the ocean crust and upper mantle as a function of spreading rate.

After a failed attempt of Hole 1415I to reenter the hole with a 14.75 inch tri-cone bit, theship shifted 10 m to the north, verified that the seafloor was free of any boulders, and observed the bit tag the seafloor at 4850.0 mbrf and Hole U1415J was spudded at 1855 h using a 14.75 inch tri-cone bit. Drilling proceeded at ~1.2 m/h from 0 to 7 mbsf and then slowed to ~0.6 m/h until total depth of 4865 mbrf (15 mbsf).

Hole U1415P was sited on the southern margin of a small promontory, between Holes U1415G and U1415O. From the onset, Hole U1415P was established as a reentry hole and was intended to be a nested FFF configuration with casing similar to that at Hole U1415J.

The primary accomplishment in Hole U1415P was RCB coring that extended from 12.5 to 107.9 mbsf and recovered 30.57 m (32%) of gabbroic rocks. In addition, material was recovered in five ghost cores obtained during hole cleaning operations in previously drilled portions of the hole (IODP 345 report).

These two holes are reentry holes In the remainder of this section, and recovered massive units as well as surficial rubble unit. The dominant rock types are troctolites and olivine gabbros for both of the site. The multi textured gabbro exhibit a wide variation in mineral mode, mineral habit (Gillis et al, 2013). Mostly, an unexpected occurrence of orthopyroxene in this primitive litho-units emphasis the importance of this research.

Chapter 3

3. Analytical method:

3.1. Modal analysis:

Sample selection was based on the degree to which they represent petrographic types and on their freshness. Two blocks of 65 and 42m thickness from holes P and two blocks of 29 and 50m from hole J obtained from IODP 345, from which 66 samples are studied for petrography and mineral chemistry. Among them 30 samples are selected to performed modal analysis by pixel counting method in ImageJ software. 20 samples from Hole P and 10 samples from Hole J are selected based on best representative samples of Olivine gabbro. These samples are chosen after detailed observation by thin section analysis by microscope.

Pixel counting was done on whole section scan by selecting and contouring each mineral. Contoured minerals were grouped by types (Ol, Plg, Cpx, Opx and oxides) in as many selections. Pixels contained in each selection were automatically counted by the software

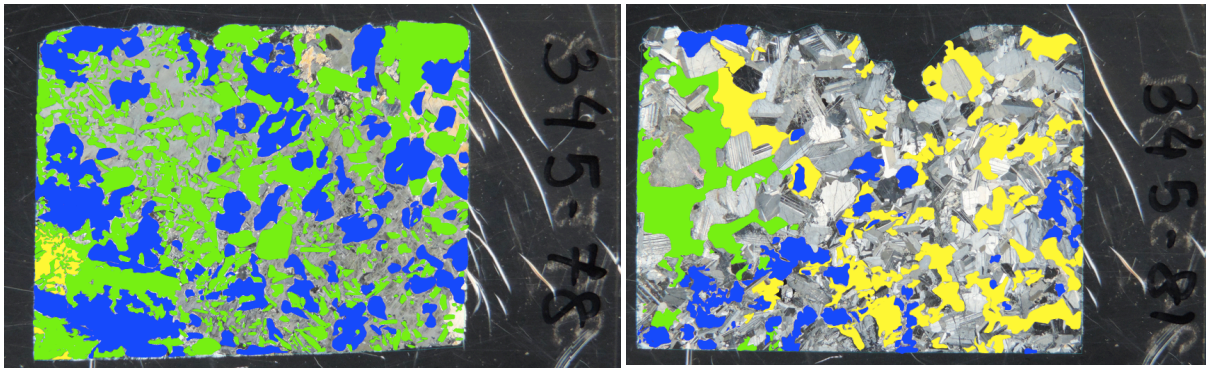

Figure 3.1: Modal analysis was done by pixel counting method. Different colours except plagioclase as it present separate contoured minerals highest in amount: blue (Ol), green (Cpx) and yellow (Opx).

imageJ, the volume percentages of each mineral were then calculated using these results and the pixel count for the total section (Fig. 4.1). This method is based on the procedure

developed by Launeau, P., and P.-Y. F. Robin (1996), which showed that precise results may be obtained by the image analysis of crystal boudaries.

3.2. Electron microprobe analysis:

Mineral chemistry were collected exclusively from representative samples (60 samples) which were selected on the basis of geochemical characteristics and expected to represent wide range of composition. Thin sections of the representative samples were polished using blue diamond solutions and were carefully carbon coated. The chemical composition of minerals in investigated rocks measured by quantitative analysis using wavelength dispersive electron probe microanalysis (JCMA- 733 and JXA-880R) installed at Hokkaido University. Analysis was performed at an acceleration voltage of 20 kV and at specimen current of 20 nA for point and line profile. The beam diameter used during analysis was 3 μm. Also elemental mapping done in one crystal of orthopyroxene.

3.3. La-ICPMS analysis:

In situ trace element compositions were determined by LA-ICPMS at Géosciences Montpellier (AETE, University of Montpellier, France). Plagioclase, clinopyroxene, orthopyroxene and olivine were analyzed using 150 μm thick polished sections. Grains were carefully selected optically to discard those affected by alteration. Trace elements analyzed were: Li, B, Sc, Ti, V, Mn, Co, Zn, Sr, Y, Zr, Nb, Ba, rare earth elements (REEs), Hf, Ta, Pb, Th and U. Analyses were performed with a Thermo Scientific Element XR (eXtended Range) high resolution ICPMS. The ICPMS was coupled to a laser ablation system consisting of a Geolas (Microlas) automated platform with a 193 nm Excimer Compex 102 laser from LambdaPhysik. Ablation analyses were performed using an in-house modified 30-cm3 ablation cell with a helium atmosphere to enhance sensitivity and reduce inter-element fractionation (Günther and Heinrich, 1999). Helium gas and ablated sample material were mixed with argon gas before entering the plasma. The laser energy

density was set to 12 J cm−2 at a frequency of 8 Hz and the beam size was set to 102 μm. Data were collected in time resolved acquisition mode, with the background signal collected for 2 min followed by 1 min of sample ablation.

Data were reduced with the GLITTER software package (Van Achterberg et al., 2001), using the linear fit to ratio method. Data were filtered for spikes on an element-by-element basis. Internal standardization relative to EMPA data was done using 29Si for all minerals. Detection limits were <1 ppb for most highly incompatible elements except for Ba, Zr and Sr (<2 ppb); they were <15 ppb for Sb, V, Cu, Zn, Co, Sc, Li and B and <200 ppb for Mn, Ti. Values that were within 1σ of the detection limit were excluded during data reduction. Instrument sensitivity due to analytical conditions was determined from the average across all days of repeat measurements of the synthetic NIST 612 glass (Pearce et al., 1997). Sensitivities were 2000-4000 cps/ppm for Ti, B and Zn, 6000-15000 cps/ppm for Li, Cu, Sb, Ba, Nd, Sm, Gd, Dy, Yb and Pb and >20000 cps/ppm for all other elements. Reproducibility as constrained by 8 analyses of reference basalt BIR 1-G (Table eA1) was better than 5% for most elements except for Pb (16%), B and Ta (<10%) and measured values were comparable within analytical uncertainties to GEOREM accepted values (Jochum et al., 2005).

3.4. Calculated melt in equillibrium:

Nominally anhydrous major-rock forming minerals in the Earth's oceanic crust include olivine, clinopyroxene (cpx), orthopyroxene (opx), spinel, and plagioclase. All elements distribute themselves unevenly between any two phase at equilibrium which is known as chemical fraction (Winter, 2010). In general, Major and REE, distribution of an elements between any two phases at equilibrium at particular pressure (P), temperature (T), oxygen fugacity (fO_2), and mineral and melt compositions (X) and can be expressed as "equilibrium constant" K. Both P and T can affect the partition coefficients of trace

elements to varying extents due to the enthalpy change and volume change, respectively, in the chemical exchange between minerals and melt (e.g., Blundy andWood, 2003;Wood and Blundy, 2003). Ryerson and Hess (1978) further suggested that mineral-melt trace element partition coefficients would increase with melt polymerization. This has been examined experimentally for trace element partitioning between olivine and basaltic melt and between cpx and melt in several recent studies (Gaetani, 2004; Mysen, 2004; Huang et al., 2006; Evans et al., 2008; Tuff and O'Neill, 2010).

If an exchange reaction of component i , between two phases – a solid & a liquid, considered, then,

$$i\ liquid \leftrightarrow i\ solid$$

A simple empirical distribution K_D, defined as constant –

$$K_D = \frac{Xi\ Solid}{Xi\ liquid}$$

' Xi ' → the mole fraction of the component ' i ' in that solid or liquid phase.

The Distribution Constant (K_D) simply states that a component has a tendency to be distributed in co-existing phases at equilibrium in a consistent & reproducible fashion . K_D values for major elements range between common phases & lie within an order of magnitude of 1.0. K_D values for trace elements range over several orders of magnitude. While dealing with trace elements, KD, replaced by d, called the Distribution Coefficient

$$D = \frac{Concentration\ of\ an\ element\ in\ the\ total\ solid\ phase\ (CS)}{Concentration\ of\ the\ same\ elemnt\ in\ the\ liquid\ (CL)}$$

D measures the degree of tendency of an element to partition itself into the total solid (inclusive of all minerals) & the co-existing liquid. A particular element has a particular value of K_D.

Chapter 4

4. Petrography of gabbroic lithologies:

4.1. Introduction:

The origin of layered structure in fast spreading ridge is controversial. Rare accessibility of lower crust in nature often compare with ophiolites, as well as from geophysical data (particularly seismic interpretation). From ocean drilling program, direct observation from crustal layers has been contributing a major scientific impact in earth science. Integrated Ocean Drilling Program (IODP) Expedition 345 aimed to sampled from lower crustal primitive gabbros (IODP Expedition 345 scientific report) at the tectonic window in fast spreading ridge East Pacific Rise (EPR), formed due to eastward propagation of Cocos-Nazca rift towards EPR and known as Hess Deep Rift. Previous expedition, Ocean drilling program (ODP) Leg 147 designed to sampled upper crustal lithologies along with uplifted upper mantle section. Based on the result from previous result IODP expedition 345 acquires the lower crustal section in order to compare with Peneros model of fast spreading ridge from Oman ophiolite.

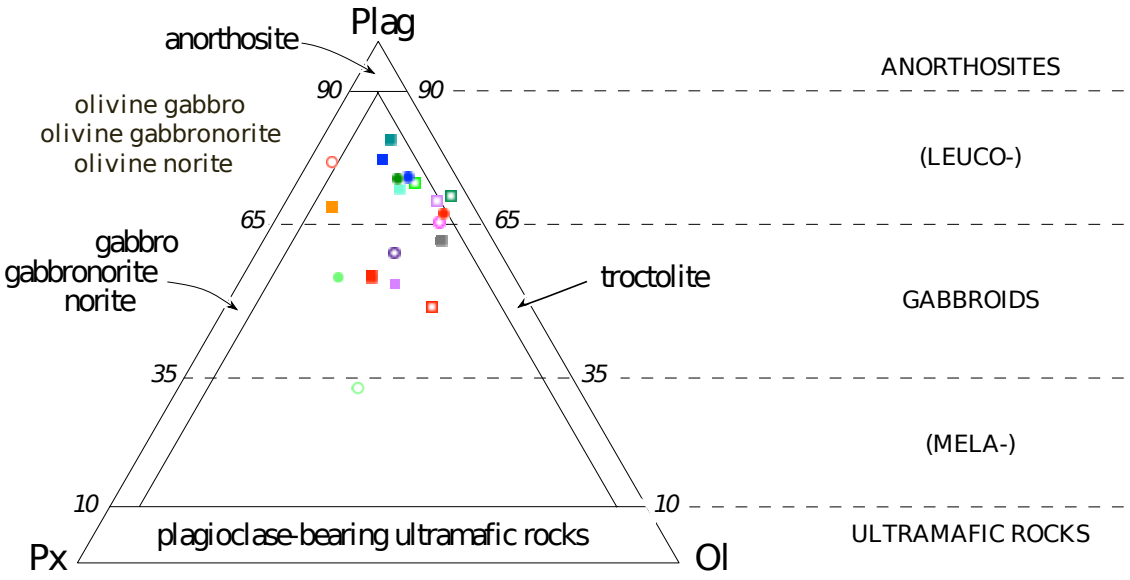

Figure 4.1: Triangular diagram showing modal plot of main constituent minerals for different samples

4.2. Upper gabbro:

4.2.1. Sampling site:

Previously from ODP leg 147 at the intrarift ridge on Hess Deep restricted to sampling depths >3000 mbsf, at approximately 2°18.0'N, 101°31.5'W, Hole 849G was drilled 18.0 m from 3034.4 to 3053.0 m (0-18.6 mbsf).only recovered upper crustal lithologies include olivine gabbros, gabbros, olivine gabbronorite, gabbronorite and patches of pegmatitic amphibole-gabbro (Gillis et al., 1993; Natland and Dick, 1996; Pedersen et al., 1996).

At site U1415, recovered overlying surficial rubbles and lithic sand beside massive blocks are fallen from unknown stratigraphic levels but which were located above the drilled samples. Only samples collected as massif blocks could be considered as lower crust rocks, the rubbles, fallen from upper or middle crust were grouped with the samples collected from ODP leg 147. Moreover, the aim of this particular study only concerns gabbroic lithologies and basalts or peridotite, either drilled during ODP Leg 147 or IODP Exp. 345, were not sampled not studied.

4.2.2. Petrographic description:

4.2.2.1. Drilled samples:

Upper crustal gabbro is usually highly altered. Olivine gabbro is usually very coarse grained and is also highly heterogenous; some irregularly shaped, olivine-rich patches are included in the leucocratic Plagioclase and clinopyroxene-rich part (Fig. 4.2.A). Olivine gabbro may be the olivine-poor equivalent to the troctolite. The olivine in olivine gabbro is similar in appearance to that in troctolite (Fig. 4.2.B). Chromian spinel is disseminated in and around some of the olivine-rich part (Fig.4.2.C). Some of the Plagioclase is euhedral and it is usually poikilitically enclosed by clinopyroxene (Fig.4.2.D & E).

Clinopyroxene is coarse and anhedral, usually poikilitically enclosing rounded olivine and euhedral Plagioclase. One of the samples is gabbronorite, consist more than 20% of

orthopyroxene in modal abundane. Clinopyroxene and orthopyroxene in gabbronorite both show poikilitic nature that encloses plagioclase (Fig. 4.2.F). Some cr-spinel present as minor phase with interstitial occurrence.

4.2.2.2. Rubbles:

A total of 8 samples are marked as rubbles, recovered from Exp. 345. These are also consist of three types of rock according to modal percentage; gabbronorite, ol-gabbro and opx-ol gabbro.

Gabbronorite consist large grain of clinopyroxene and orthopyroxene with ophitic texture, enclose plagioclase laths (Fig 4.3.A). Some of the portion of this rocks are altered to chlorite, may be hydrothermal alteration effect.

Olivine gabbro shows a very little alteration, only secondary amphibole produce around olivine. Olivine otherwise present as very unaltered phase with interstitial and subhedral crystalline form. Olivine also present as poikilitic in nature with plagioclase (Fig 4.3.B), co-crystallization may be best approximation in this case. Clinopyroxenes are tabular and mostly present as ophitic in relation with plagioclase. Two samples are Opx-ol gabbros, and consist 2-3% of Opx, 15-20% of Cpx, 5-10% od Ol and 50-60% of plagioclase. Olivines are very altered along the fracture but retain their shape (Fig 4.3.C). Orthopyroxene present as interstitial phase within plagioclase (Fig 4.3.D) and also as prismatic crystals (Fig 4.3.E). Also a few percentage of cr-spinel present in the gabbroic rocks (Fig 4.3.F)..

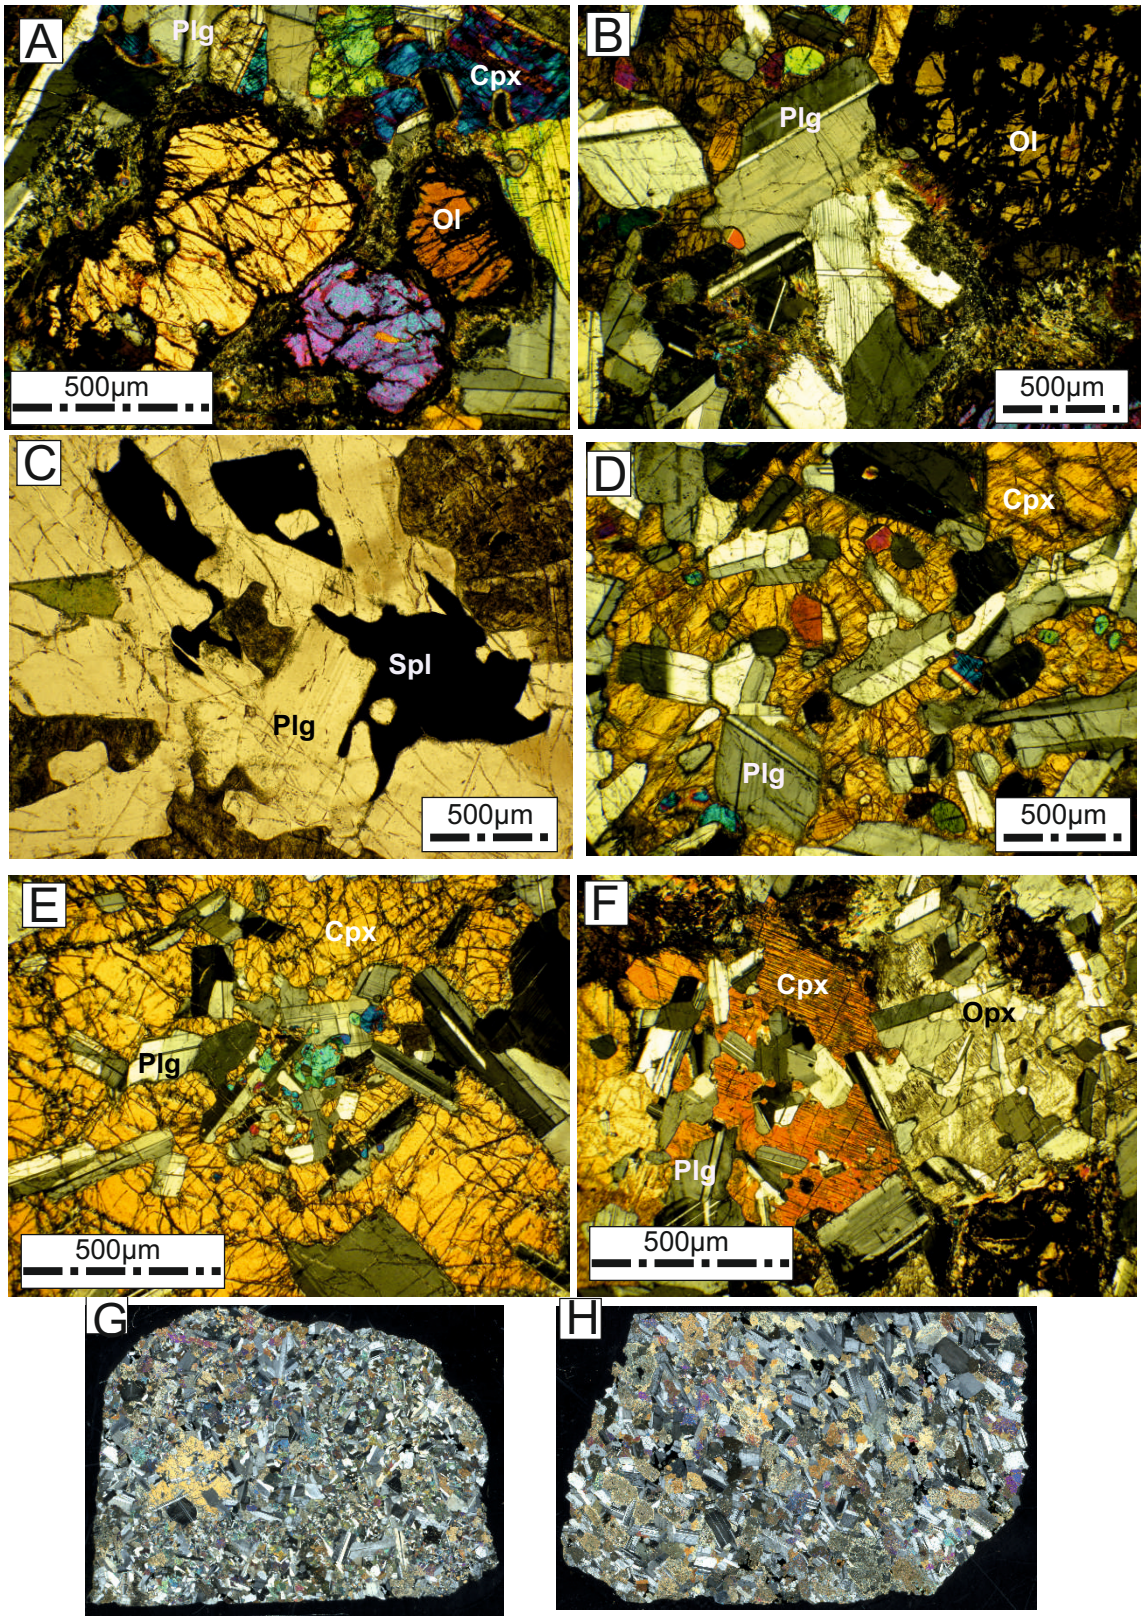

Figure 4.2: Photomicrogharph of upper gabbro samples from ODP 147 (A) Very coarse grained irregularly shaped, olivine-rich patches in the leucocratic Plagioclase and clinopyroxene-rich part, (B) The olivine in olivine gabbro is similar in appearance to that in troctolite, (C) Chromian spinel is disseminated in and around some of the olivine-rich part, (D and E) Euhedral Plagioclase poikilitically enclosed by clinopyroxene, (F) Poikilitic clinopyroxene and orthopyroxene, (G) Thin section of gabbronorite, (H) thin section of ol-gabbro

4.3. Lower gabbro:

4.3.1. Sampling site:

Site U1415 is located along the southern slope of the intrarift ridge between 4675 and 4850 mbsl (Fig. 2.1). Lower crustal plutonic rocks recovered from IODP 345 with a wide range of lithologies like, Troctolites, Olivine gabbros, Clinopyroxene oikocryst bearing gabbros, gabbronorite). Olivine gabbro is the dominant rock type recovered at Site U1415, occurring in both the layered series in Holes U1415J, and U1415P and the Troctolite Series in Hole U1415P particularly. An unexpected observation is the predominance of

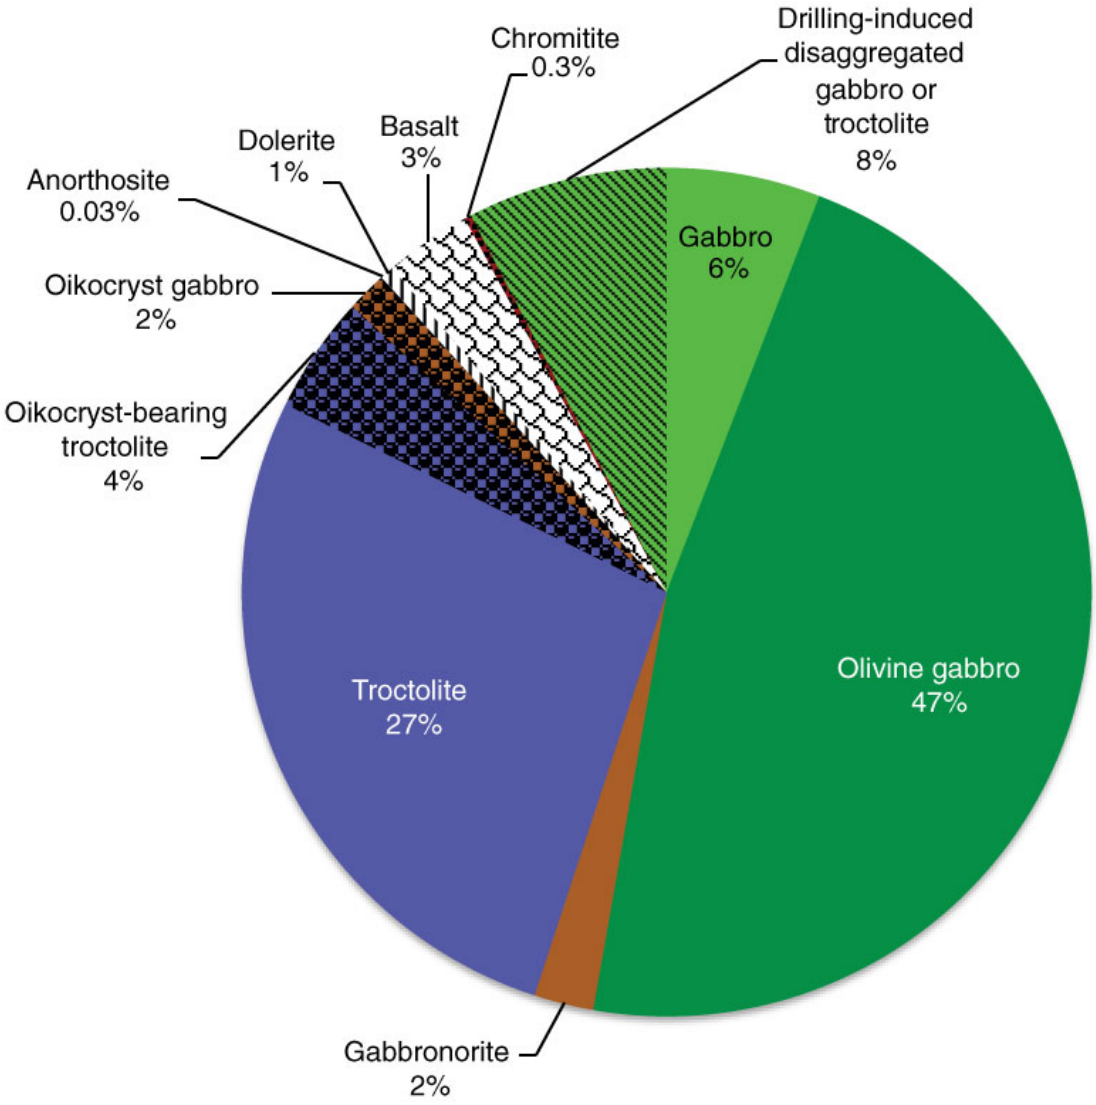

Figure 4.4: Chart showing the relative proportion of all recovered igneous lithologies from site 1415 (Exp. 345 scientific report)

orthopyroxene-bearing lithologies, particularly present in Hole P, and in some of the samples from Hole J.

Here we have selected 66 Hess Deep gabbroic rocks for this study. Hole J, consistency in the dip of magmatic foliation and magnetic inclinations identify two discrete blocks with vertical thicknesses of 29 and ≥50m (Fig 4.5 A,B).. In Hole P, rock type and magnetic inclinations suggest two blocks of 65 and >42 m thickness (Fig 4.7 A,B). The primitive lithologies at Site U1415 formed at a minimum of 2 km beneath the sheeted dike complex, at the lower half to one-third of the 3.8–4.8 km thick plutonic sequence (Expedition 345 Scientific report).

4.3.2. Petrographic description:

4.3.2.1 Hole J:

From the Exp. 345 report, Gabbros primarily occur in centimeter-scale intervals in the layered series in Holes J where they are fine to medium grained, and have an equigranular/granular texture. Ol-gabbro and Cpx-oikocryst gabbro are dominant rock types Hole J. Ol-gabbros were recovered at ~110m deep at holes and J. The lower gabbroic series is marked by simple modal layering with variation of grain size on centimeter to decimeter scale (Gillis et al; 2013).

Layered gabbros from Hole J consists of a ~30 m thick sequence (IODP 345 Scientific repot; 2013) with overall adcumulus texture with ophitic to subophitic domain consisting of plagioclase ~ 55-70%, olivine ~ 10-20%, Clinopyroxene ~ 20-30% and minor orthopyroxene ≤ 2%. Olivine present as subhedral to euhedral, also olivine present as skeletal in nature (Fig. 4.6.A). Plagioclases are euhedral to subhedral, some of the plagioclase are altered by cholitic mineral along fracture (Fig. 4.6.B).. Ophitic nature is prevail in plagioclase which is marek by enclose by clinopyroxenes (Fig. 4.6.C).. Larger

oikocrystic clinopyroxene present as patches in some section and encloses olivine and plagioclase (Fig. 4.6.D).. Some of the sample (here we have only 6 samples) consists of orthopyroxene mainly as oikocryst in reaction with plagioclase chadacryst (Fig. 4.6.E). or as prismatic in shape (Fig. 4.6.F).. But modally they are less in amount than we observed in Hole P samples.

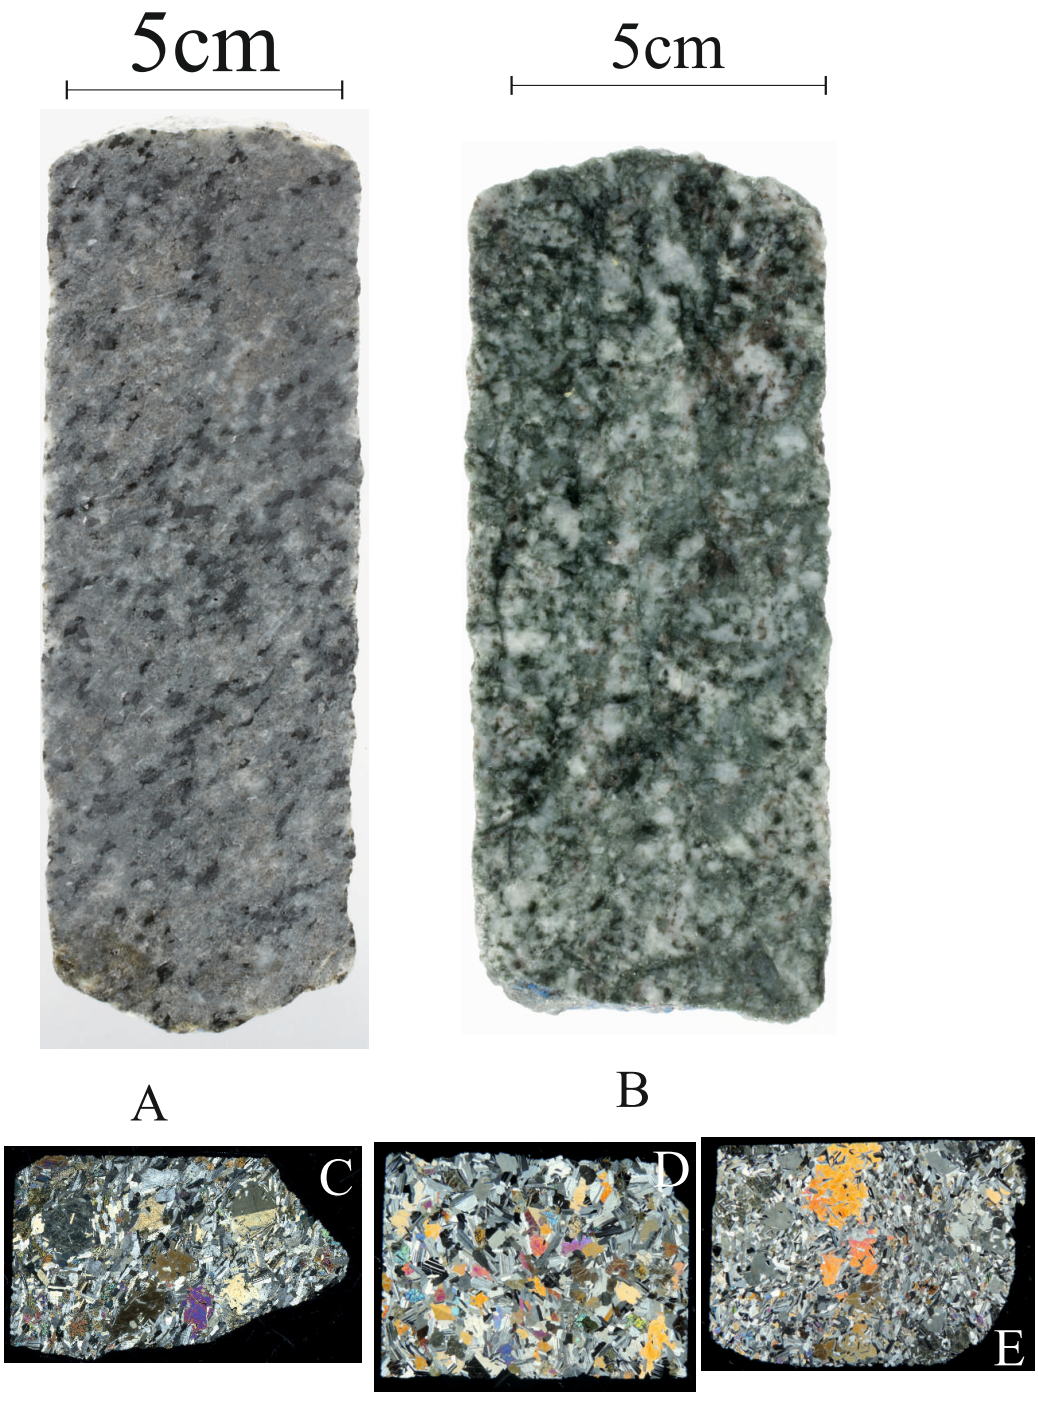

Figure 4.5: Core samples from IODP 345 U1415 J, (A) Opx-ol gabbro, (B) Ol gabbro, Thin section of (C) Oikocryst ol-gabbro, (D) Ol-gabbro, (E) Opx-Ol gabbro

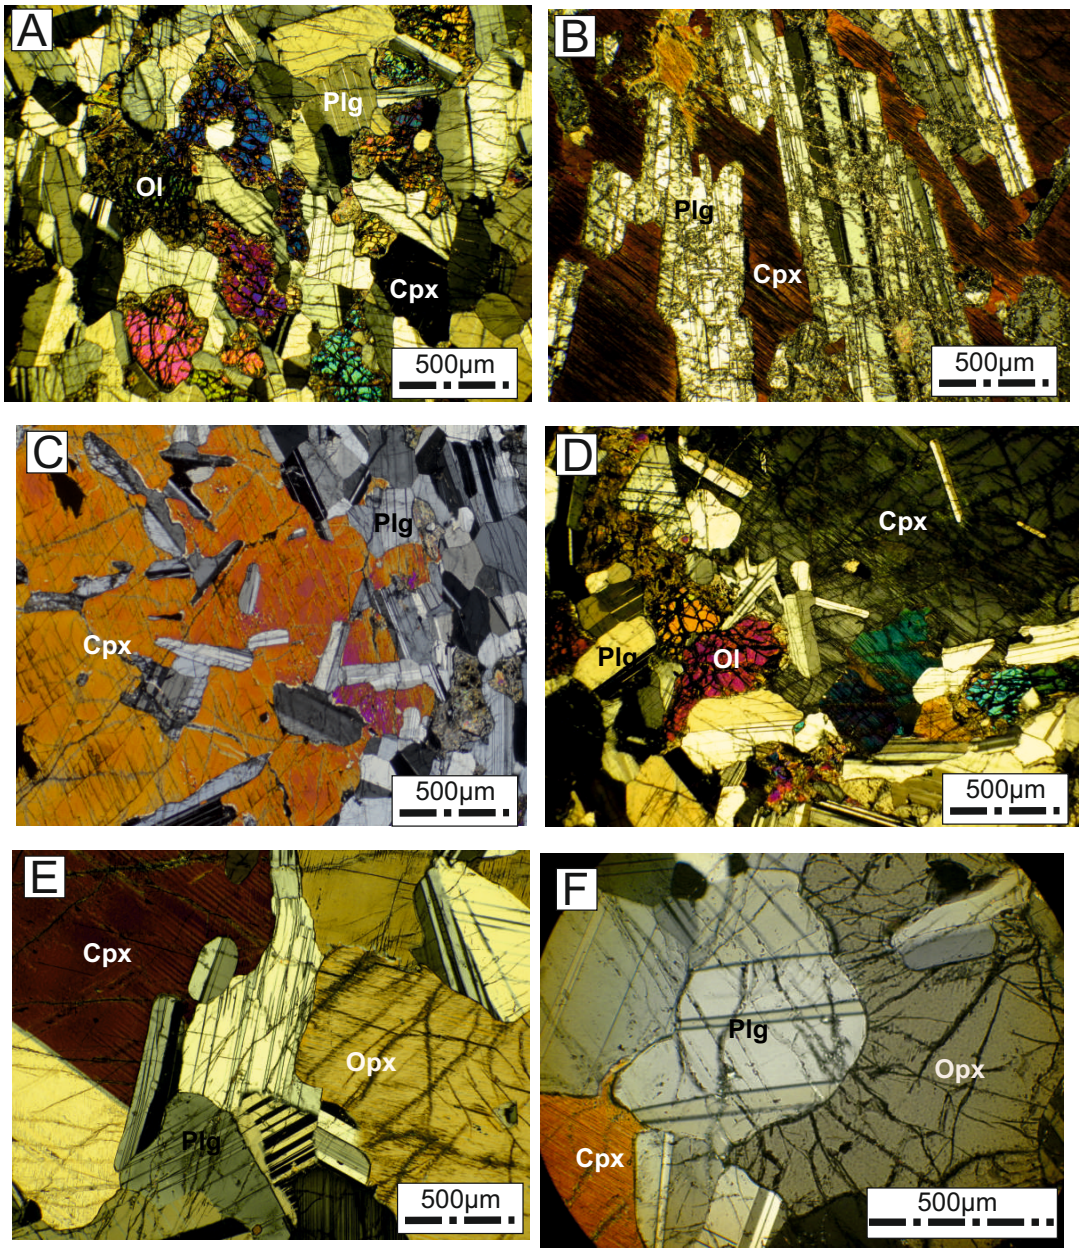

Figure 4.6: Photomicrogharph of lower gabbro samples from Hole U1415 J (A) Olivine present as skeletal in nature, (B) Plagioclase are altered by cholitic mineral along fracture, (C) Ophitic nature of clinopyroxenes, (D) Oikocrystic clinopyroxene encloses olivine and plagioclase, (E) orthopyroxene mainly as oikocryst in reation with plagioclase chadacryst and also (F) prismatic in shape

4.3.2.1 Hole P:

An astonishing observation is the prevalence of orthopyroxene-bearing lithologies, predominately orthopyroxene-bearing olivine gabbros and minor olivine-bearing gabbronorite. It was seen on classical model of fast spreading ridge, that, orthopyroxene should appear in isotropic gabbro at a later stage of crystallization and designated as gabbronorite (Grove et al, AGU, 1992). It should be present as minor interstitial grains in olivine free lithounits. In contrast to Hess Deep we found orthopyroxene rich lithologies from lower part. Presence of orthopyroxene dominated in hole P rather in Hole J. Lithologies obtained from Hole P composed Ol-gabbros were recovered at ~110m deep at reentry holes P. The lower gabbroic series is marked by simple modal layering with variation of grain size on centimeter to decimeter scale like Hole J (Gillis et al; 2013). Gabbroic lithologies are grouped into different units (IODP 345 Scientific repot; 2013), olivine gabbro, Opx-Ol gabbro, cpx-oikocryst gabbro. Varitextured layers of gabbro with ~ 50 cm thick sequence (IODP 345 Scientific repot; 2013), consists of plagioclase ~ 60-70%, olivine ~ 15-20%, Clinopyroxene ~ 15-25% and orthopyroxene 1- 5 %, two of the studied sample consist more than 12% of orthopyroxene. Olivine present as subhedral to euhedral nature with amoeboid or skeletal habit (Fig 4.8.B). Tabular plagioclase often present as chadacrysts enclosed by clinopyroxene (Fig 4.8.D). Also palgiocalse are showing recrystallization texture marked by triple junction and often rounded in shape (Fig 4.8.C). Three types of Opx textures may be distinguished in Opx-bearing olivine gabbros (1) recrystallised corona around olivine (Fig 4.8.E)., (2) exsolution within clinopyroxene (Fig 4.8.G,H). and (3) large prismatic or poikilitic grains (Fig 4.8.F).. Overall texture points to a crystallisation order starting with olivine and plagioclase, and finishing with clinopyroxene and then orthopyroxene. From the Exp. 345 scientific report, it is reported that Orthopyroxene-bearing olivine gabbros present as monogenously to dramatically banded or layered. Banding of these gabbros divided into two broad categories: steeply

dipping, asymmetric and sometimes diffuse leucocratic banding and less common, more regular, gently dipping grain size and modal layering (345 scientific report)

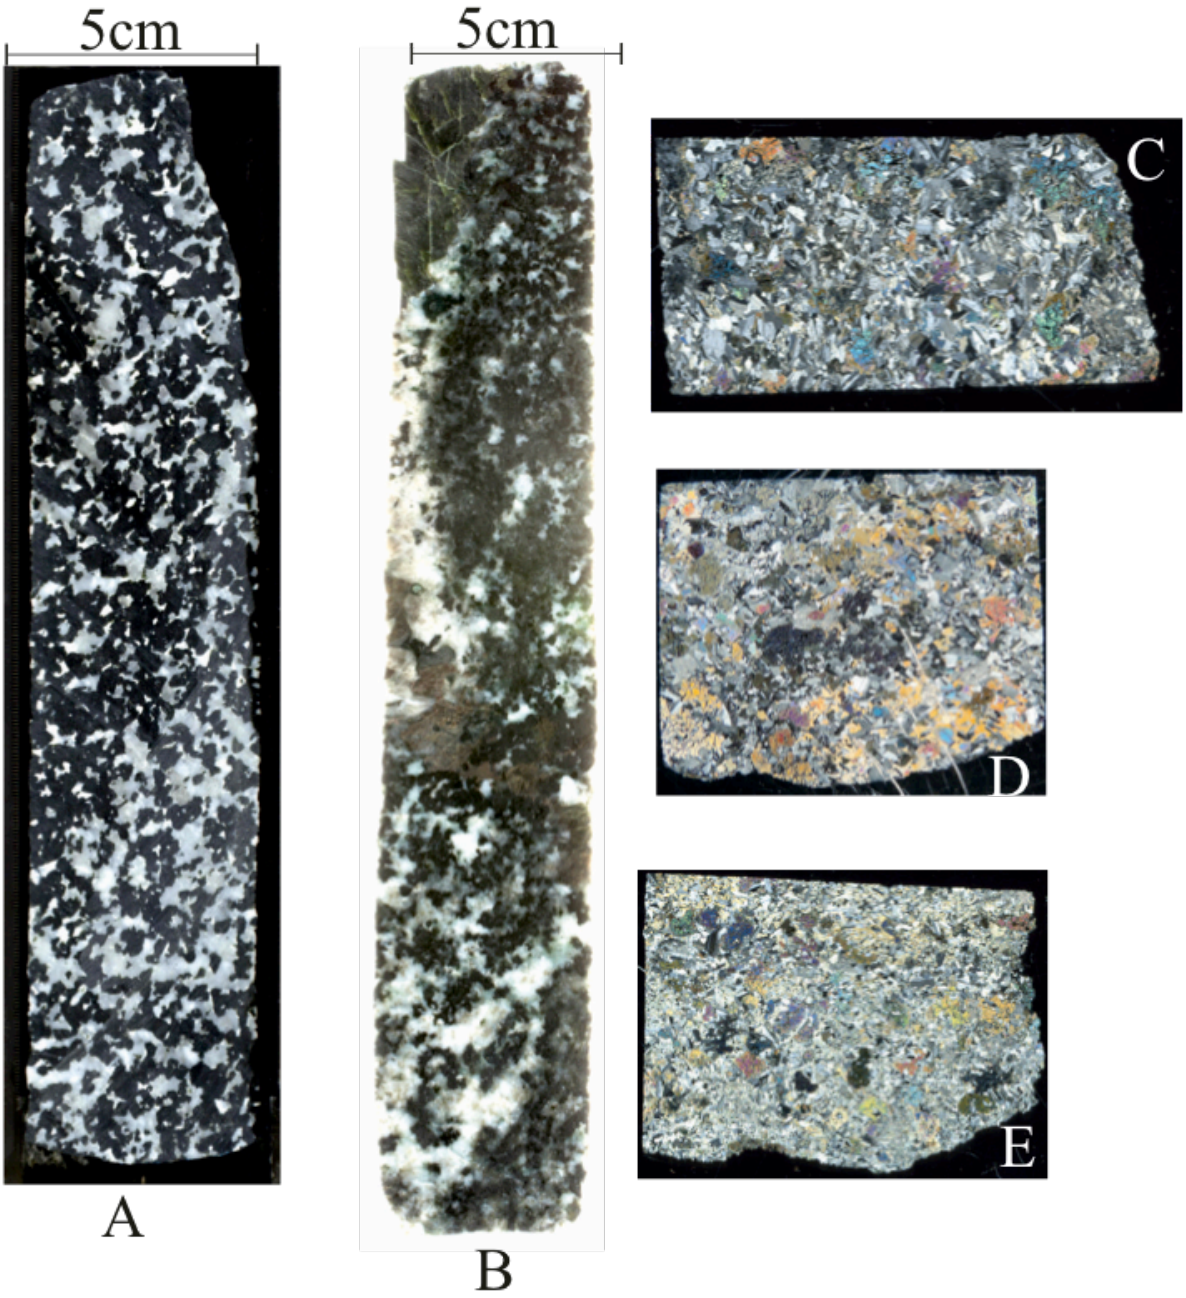

Figure 4.7: Core samples from IODP 345, U 1415 P, (A). Troctolite,(B)Opx-Ol gabbro, Thin section of (C) Troctolite ,(D) Ol-gabbro,(E) Opx-Ol gabbro

(A) Typical cumulate texture of Ol-gabbro, (B) Ol shows skeletal nature (C) plagioclase shows recrystalline texture, (D) Cpx encloses lath of plg and rounder ol, (E) Opx present as corona around olivine, (F) Prismatic opx, (G and H) Interfingered relationship of cpx and opx

Chapter 5

5. Mineral Chemistry:

5.1.Chemistry of main mineral content with depth in Hole J and Hole P:

In Fig 5.1 shows the chemical evolution with depth for the main mineral content in Hole J. Along the depth troctolitic rock present all along the column with ol-gabbro, gabbro and gabbronorite at upper 70 mts (IODP 345 scientific report). A few orthopyroxene bearing lithologies present in Hole J (here we have 6 samples). The main minerals, olivine, clinopyroxene, orthopyroxene and anorthite plagioclase are shown with their Mg# content along the depth. For olivine the percentage of Fo content decrease along the depth from bottom to top, from troctolite to gabbroic lithologies. Clinopyroxene Mg# also decrease from bottom to top, as the higher percentage of Mg# (92-90%) is present in troctolite. Both troctolite and gabbroic rocks are showing scatter in a single sample. Presence of orthopyroxene is very low in Hole J and only present in Gabbroic lithologies. Mg# of Opx also decreases from higher depth to lower (85-78%). Much scatter anorthite composition present in troctolitic and gabbroic rock in Hole J and the percentage varies between 95-75% for troctolite and 85-65% for gabbroic rocks.

Fig. 5.2 (A) shows the chemical evolution with depth for the main min content in Hole P. Two series of rock are prominent in this depth column,

- The first series is Troctolitic
- The second series is represented by orthopyroxene bearing ol-gabbros.

The first series present below 70mts. Troctolilic rocks are very rich in Fo (90-84%) content of olivine and having no trend for decreasing concentration along depth. Same behavior can be noted for Mg# of clinopyroxene and anorthite content in plagioclase. Clinopyroxene Mg# has little scatter for some samples, varies between 92-85% and narrower range in plagioclase anorthite content, i.e., 90-88%. Orthopyroxene bearing lithologies (ol-gabbro and opx-ol gabbro) present above 70mts. Fo content of olivine

slightly get enrich in upper section. Mg# of clinopyroxenes are much scatter (80-92%)than the clinopyroxene present in troctolite. Similarly anorthite content of plagioclase much scatters in gabbroic lithologies (65-90%) and one single sample cover the whole range of concentration. HoleP troctolite also devoid of orthopyroxene and having narrow Mg# scatter than clinopyroxene and plagioclase. Only upper most part around 20mts, Mg# getting increase from 84 to 88%.

Fig 5.2 (B) shows the chemical evolution with depth for the only orthopyroxene in Hole P for Ol-gabbro and Opx-ol gabbro.. The Mg# remained in the first column and, in the order, TiO_2, Al_2O_3 and Cr_2O_3. The vertical trend is observable for other Opx chemical characteristics. Mg# is homogeneous in single sample but large scatters are observed for Ti, Al, Cr; one single sample cover the whole range of concentration. In accordance with the slight increase in Mg# at the uppermost 20m, Ti slightly decreases and Cr and Al increase.

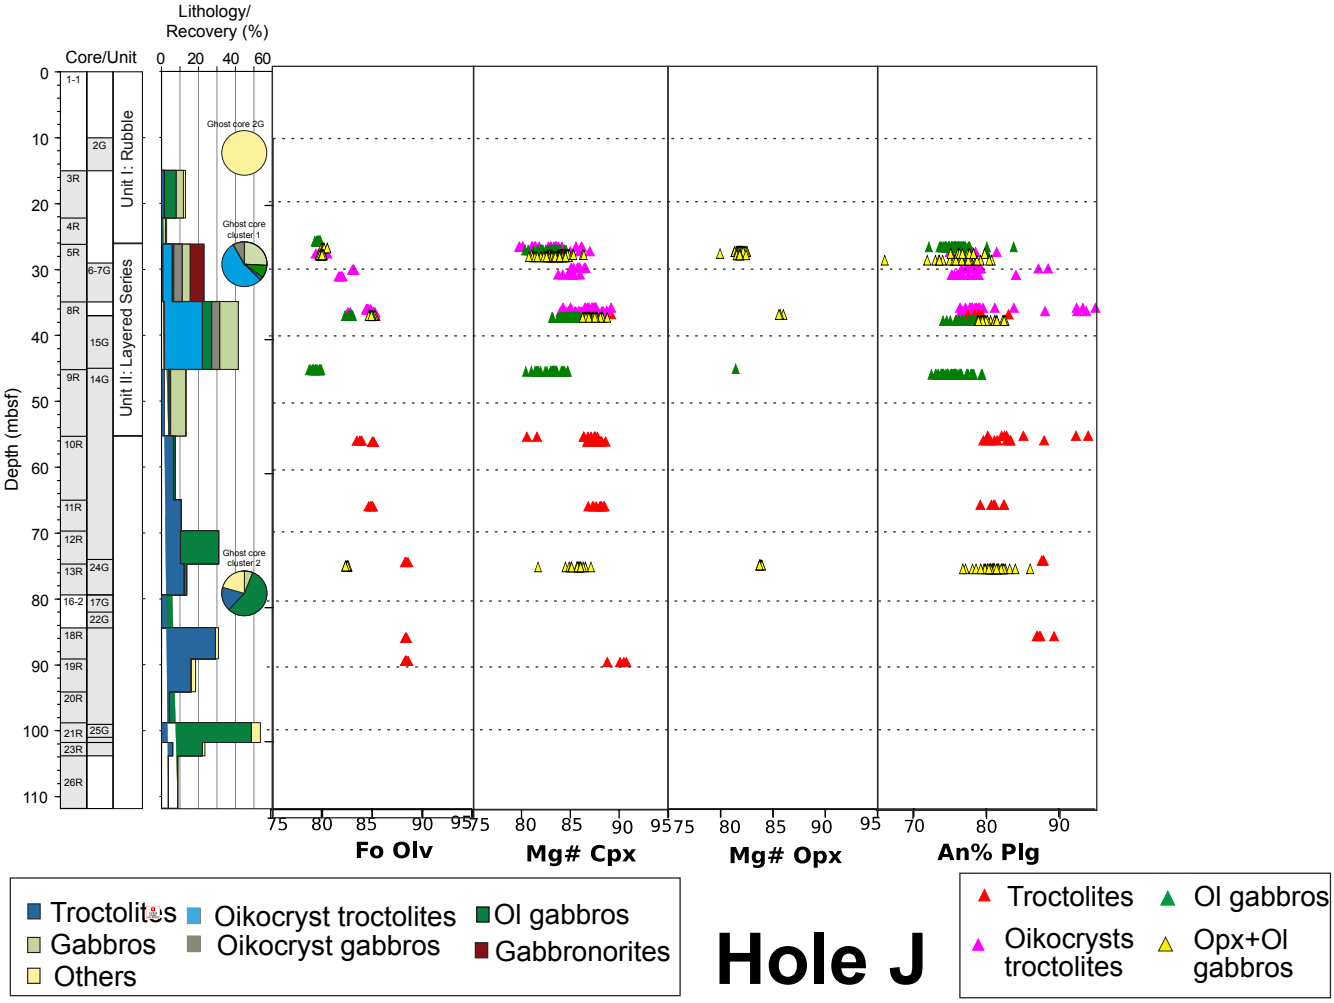

Figure 5.1: Downhole variation of the mineral chemistry of Hole J. It is notable that presence of Opx is less significant and the troctolite rest over altered unit (IODP report 345)

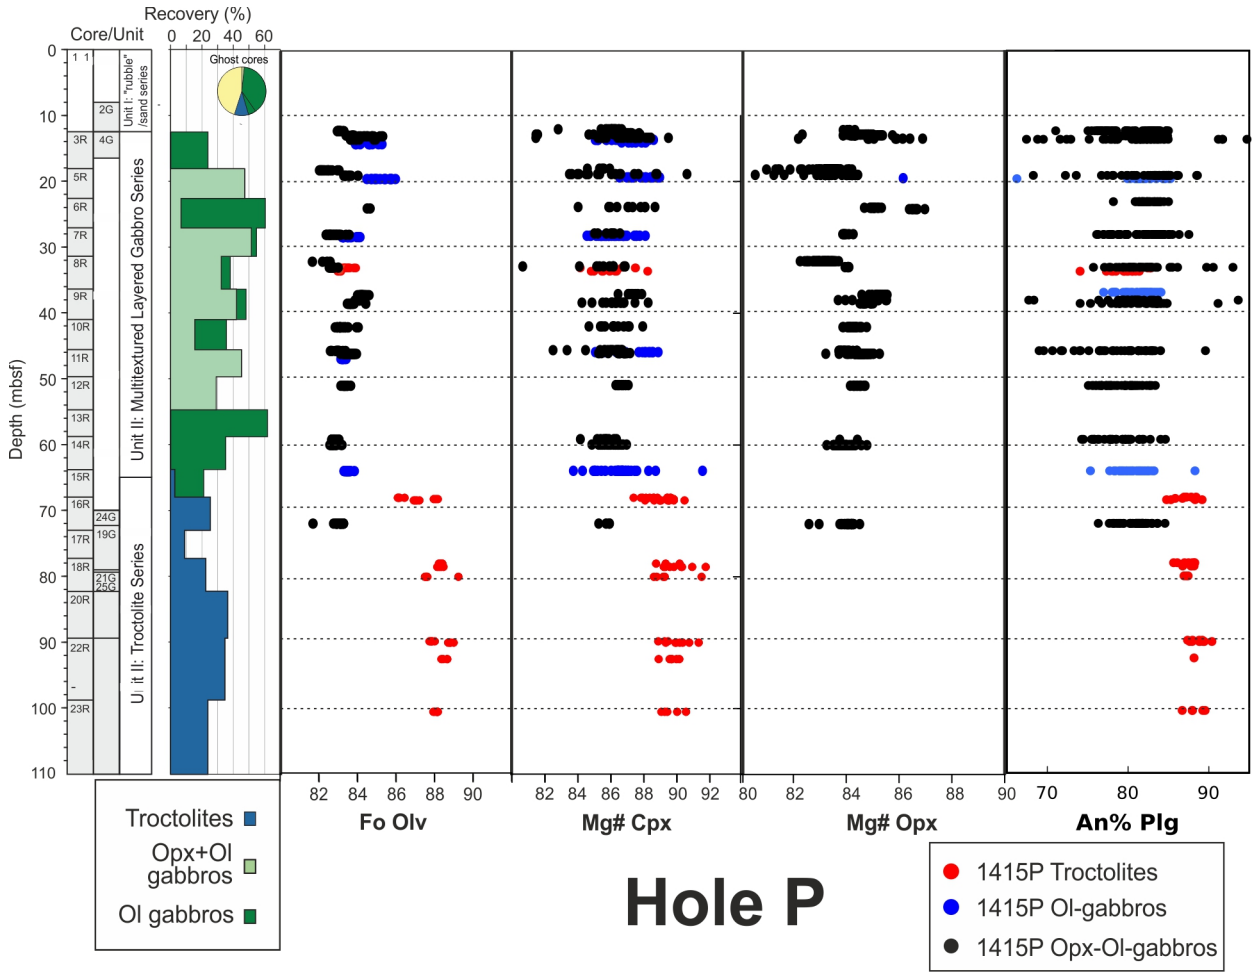

Figure 5.2 (A): Downhole variation of the mineral chemistry of Hole P. It is notable that presence of Opx is more than Hole J and the olivine gabbro is much pronounced and rest over troctolititic unit (IODP report 345)

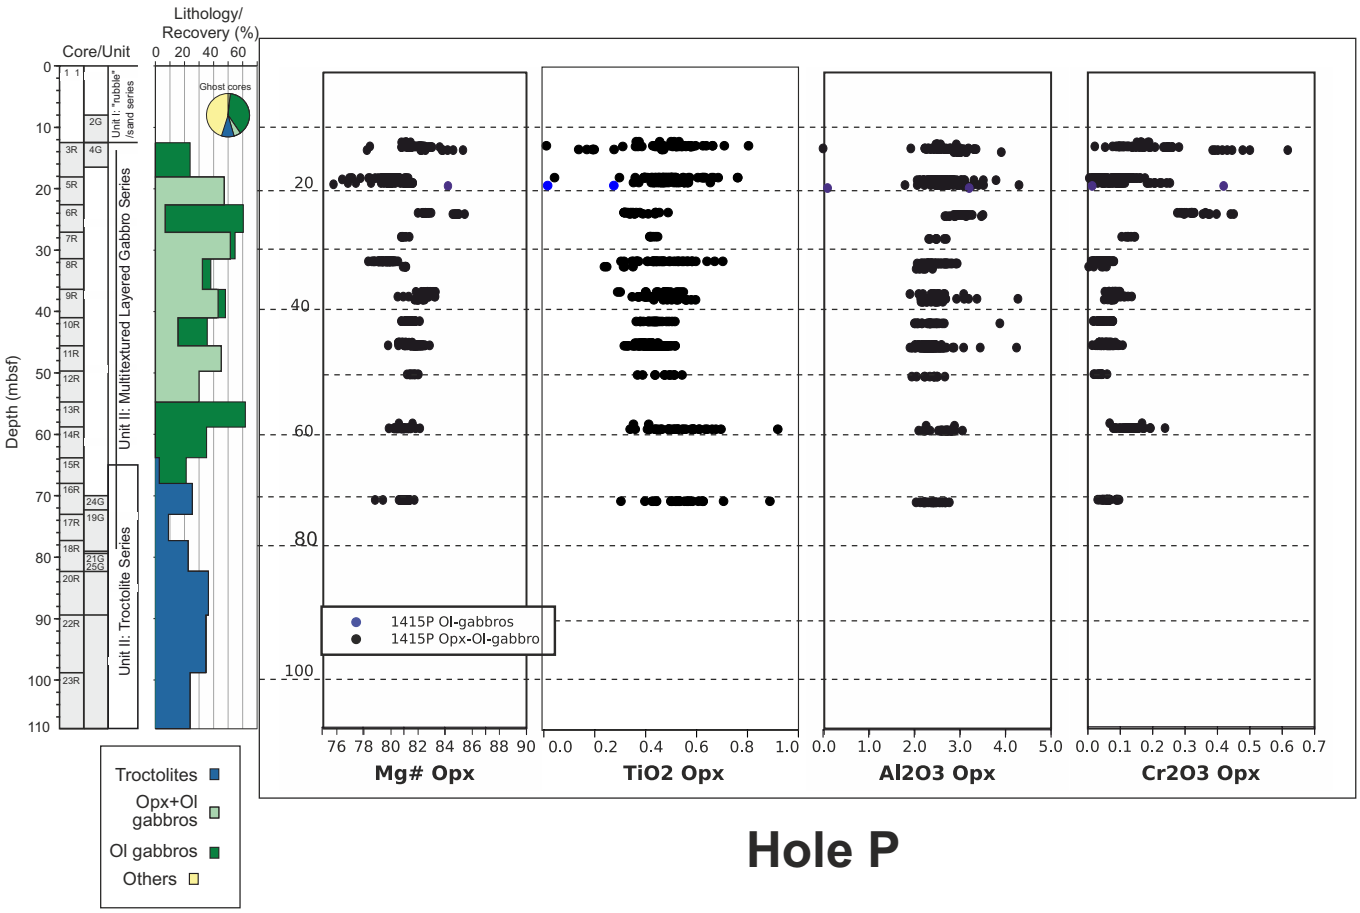

Figure 5.2 (B): Downhole variation of the mineral chemistry of Hole P. It is notable that presence of Opx is more than Hole J and the olivine gabbro is much pronounced and rest over troctolititic unit (IODP report 345)

5.2. Major element chemistry:

5.2.1. Plagioclase:

Plagioclase from Hess Deep ridge has wide compositional range from different kind of lithologies, form troctolite, ol-gabbro, opx-ol gabbro, and in the upper gabbro. Hole J and P plagioclase shows normal, reverse, patchy and oscillatory zoning. Anorthite contains in upper gabbro from ODP leg 147, ranges from 65-76%. Rubbles from 1415 holes range from 80-85%. Although more enriched samples are troctolites but opx-ol gabbros both for Hole P and Hole J, 65-90% and 65-80% respectively (Fig5.3 D).

Anorthite vs. Mg# of coexisting clinopyroxene show a decreasing Mg# with Anorthite from troctolitic series to lower gabbroic lithologies then upper gabbro. Where upper gabbro and rubbles along with Hole J are having trend, Hole P gabbros are making a cloud rather following the trend (Fig5.3 D).

5.2.2. Olivine:

Olivine geochemistry (Fig.5.3 A) of the upper crustal gabbros chemistry has lower value of Fo content in respect to other lithologies. It ranges 62-68% in Fo content and 0.02-0.1% in NiO.

Rubbles collected from IODP Exp. 345 are much enriched than upper gabbro from ODP leg 147. Their Fo content varies from 75-80% with higher NiO content of 0.08-0.15%.

Hole J olivine samples are following the trend and enriched than the rubbles with Fo content 80-85% and NiO content 0.7-0.18%.(Fig. 5.3 B)

Hole P ol-gabbro and opx-ol gabbro having narrow range of Fo content particularly in opx-ol gabbro (82-85). Ol gabbros are also having same range but few sample having Fo

content more than 85%. NiO content also much higher than Hole J, 0.1-0.2% with samples of ol-gabbro having high Fo have more than 0.2% of NiO contain (Fig. 5.3 B)

All samples from Hole J and P show enriched characteristics as Olv Fo content is always over 80. Although the most enriched samples shown on Olv Fo vs NiO are troctolites and Opx bearing lithologies are regrouped after troctolites within the general trend (Fig. 5.A,B).

5.2.3. Clinopyroxene:

Clinopyroxene mineral chemistries are shown in figure 5.4. Upper gabbro clinopyroxene have wide range in Mg# from 70-92 with TiO_2 ranges from 0.02-0.9% (Fig. 5.4 A), Cr_2O_3 from 0.01-1.2% (Fig. 5.4 B), and Al_2O_3 1.2-2.5% (Fig. 5.4 C). TIO_2 vs. Mg# of clinopyroxene shows an increasing trend of titanium concentration with decreasing Mg#, an increase trend of Cr_2O_3 and Al_2O_3 with increasing Mg#.

Rubbles from 1415 Holes also having wide range of Mg# in Cpx, 78-88% with TiO_2 ranges from 0.01-0.8% (Fig. 5.4 A), Cr_2O_3 from 0.02-0.8% (Fig. 5.4 B) and Al_2O_3 from1-4% (Fig. 5.4 C). The major element are also showing a relationship with values of Mg#. TiO_2 increases with decreasing Mg#, Cr_2O_3 and Al_2O_3 increases with increasing Mg# of Cpx.

Hole J clinopyroxene contain higher value than ODP 147 samples and almost same values of rubbles in terms of TiO_2, Cr_2O_3 and Al_2O_3, but having higher range of Mg# that varies between 80-88% (Fig 5.4 A, B,C).

In contrast Hole P show narrow value ranges for Mg# (~85-88%) but a large variation in TiO_2 (0.01-1.5%) (Fig. 5.4 A) and Cr_2O_3 (0.02-1%) (Fig. 5.4 B) Cpx. Al_2O_3 contain is restricted between 1-4% in major data cloud and some of the gabbroic samples having Al_2O_3 contain upto 7% (Fig. 5.4 C). Cpx Ti content is high in troctolites but the highest values are observed in Opx-bearing lihtologies.

Comparision with previous gabbroic lithounit from EPR data show a trend of decreasing Mg# with increasing TiO_2 and decreasing Al_2O_3 (Fig. 5.4 D). The data cover along the trend of lower crustal to upper crustal gabbro units.

Cpx Mg# vs Ol Mg# in Fig 5.5 shows, equilibrium values between coexisting ol and cpx by the solid line and the dashed lines define equilibrium composition with uncertainties of 0.02 for both kd values of minerals. Here from troctolite to Hole P and then Hole J gabbros are following the line of equilibrium.

5.2.4. Orthopyroxene:

Orthpyroxene mineral chemistries are shown in figure 5.5. Upper gabbro orthopyroxene have range in Mg# from 68-74% with TiO_2 (Fig. 5.6 A) ranges from 0.2-0.5%, Cr_2O_3 (Fig. 5.6 B) from 0.01-1%, and Al_2O_3 0.8-1.5% (Fig. 5.6 C). Cr_2O_3 and Al_2O_3 vs. Mg# of orthopyroxene shows an increasing trend of increasing Mg#.

Rubbles from 1415 Holes having wide range of Mg# in Opx, 74-83% with TiO_2 ranges from 0.2-0.4% (Fig. 5.6 A), Cr_2O_3 from 0.01-0.2% (Fig. 5.6 B) and Al_2O_3 from1-1.5% (Fig. 5.6 A). The major element are also showing a relationship with values of Mg#. TiO_2, Cr_2O_3 and Al_2O_3 increases with increasing Mg# of Opx.

Hole J orhtoyroxene are present very few in amount. But has much higher value than samples from ODP leg 147 and rubbles. TiO_2 values for Hole J orthopyroxene has a range from 0.2-0.5% (Fig. 5.6 A), Cr_2O_3 its 0.01-0.6% (Fig. 5.6 B) and Al_2O_3 1-1.2% with 82-84% of Mg# (Fig. 5.6 C).

A large scatter in TiO_2 present in Opx in Hole P ol-gabbro and opx-ol gabbro (0.2-0.85%) with narrow range of Mg# (83-87%) (Fig. 5.6 A). Also Cr_2O_3 having large scratter from 0.01-0.6% (Fig. 5.6 B) and Al_2O_3 with 1-2.5% (Fig. 5.6 C). One sample consist total range of TiO_2 with almost no variation in Mg#. This feature is particular in case of Hole P, and is thus very different from Hole J chemistry.

Comparison with previous gabbroic lithounit from EPR data show a trend of decreasing Mg# with increasing TiO_2 and decreasing Al_2O_3 (Fig. 5.6 D). A very few opx analysis make this comparison difficult but make this present study more obvious as there are very few previous work done with opx-bearing lithologies from lower crust.

5.2.5: Spinel:

In the triangular plot (Fig 5.7 A), is the spinel chemistry shows mostly Fe-chromite to Al-chromite composition and a few Cr-spinel in Hole P gabbros. There is a trend present from Al-chromite to iron enrichment for both of ol gabbros and opx-ol gabbros.

Spinel TiO_2 vs Fo content of coexisting olivine of hole P showing a narrow values for Fo content rather they have vertical trend in wide range of TiO_2 from 0.02-2.6% (Fig: 5.7 B).

Cr# vs Mg# of Hole P Ol-gabbro and opx-Ol gabbro shows a trend with increasing Mg# with decreasing Cr# (Fig: 5.7 C).

(B) TiO2 Spinel vs. Fo content of coexisting olivine Opx bearing lithogies show vertical trend of TiO2 variation, (C) Mg# Vs Cr# of Hole P lithologies with two samples from Upper gabbro.

5.3. Trace element:

5.3.1. Plagioclase:

Plagioclase trace element concentrations are given in Annex. The opx-ol gabbro samples from Hole P and J shows same trace element pattern for Chondrite Normalized, N-MORB normalized and Primitive mantle Normalized pattern, with positive europium anomaly with decreasing concentration from LREE to HREE (Fig 5.8 A). The concentration of primitive mantle normalized value of Cerium, Praseodymium, Lead and Neodymium vs. anorthite content of plagioclase show increasing trend with increasing anorthite (Fig. 5.9 A, B, C, D). Only one sample from Hole P having very differnent concentration and this sample is also highly enrich in Ti concentration.

5.3.2. Olivine:

Olivine in opx-ol gabbro samples from Hole P and J shows same trace element pattern for Chondrite Normalized, N-MORB normalized and Primitive mantle Normalized pattern. Only two samples from Hole P are showing higher enrichment of REE and are out of main data cloud, those are marked as blue line. The concentration of Chondrite normalized value of Hole P are compared with troctolite data from Exp. 345, and it the enriched samples and a few samples from general data cloud are showing same composition of troctolite. Only one sample from Hole P having very different concentration and this sample is also highly enrich in Ti concentration. Olivine has very steep in HREE slope in general, such that concentrations in Ytterbium, Thulium, Erbium, Holmium And Terbium. Cerium, Zirconium, Srontium also strongly depleted. The concentration primitive mantle normalized concentration of Lutetium, Ytterbium and Holmium vs. Fo content of olivine shows no correlation rather higher value of REE has Lower value of Fo content in Hole P olivine (Fig. 5.9 E, F, G)

5.3.3. Clinopyroxene:

Clinopyroxene in opx-ol gabbro samples from Hole P and J shows little differnt trace element pattern for Chondrite Normalized, N-MORB normalized and Primitive mantle Normalized pattern. Hole P sample are showing two types REE pattern, one, having higher europium anomaly marked as red and other samples have relatively low europium anomaly. The last samples are same as Hole J samples with almost flat Eu anomaly (Fig 5.8 C). Other than these the pattern is general. The concentration primitive mantle normalized concentration of Eu/Eu* vs. Mg# of coexisting clinopyroxene shows linear trend with increament of Mg#. Other than this, Ytterbium, Titanium and Zirconium has no such correlation rather higher value of REE has Lower value of Mg# content in Hole P clinopyroxene (Fig. 5.9 H, I, J)

5.3.4. Orthopyroxene:

Orthopyroxene in opx-ol gabbro samples from Hole P and J shows same trace element pattern for Chondrite Normalized, N-MORB normalized and Primitive mantle Normalized pattern, with strong negative europium anomaly with increasing concentration from LREE to HREE (Fig 5.8 D). Only two point from same sample shows very high enrichment, which are also high in titanium concentration. The concentration of primitive mantle normalized value of Cerium, Praseodymium, Neodymium and Zirconium vs. Mg# content of orthopyroxene show no correlation (Fig. 5.9 L, M, N, O). Only one sample from Hole P having very different concentration, which is also highly, enrich in Ti concentration.

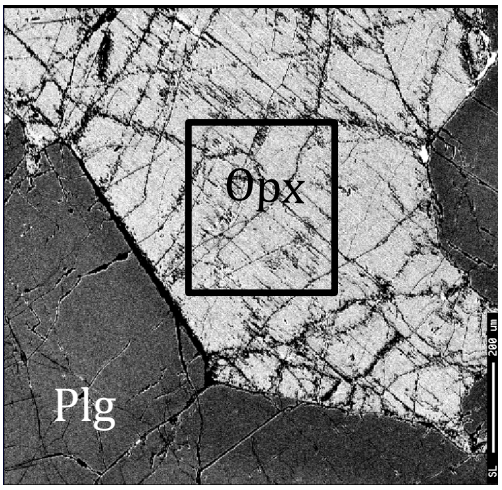
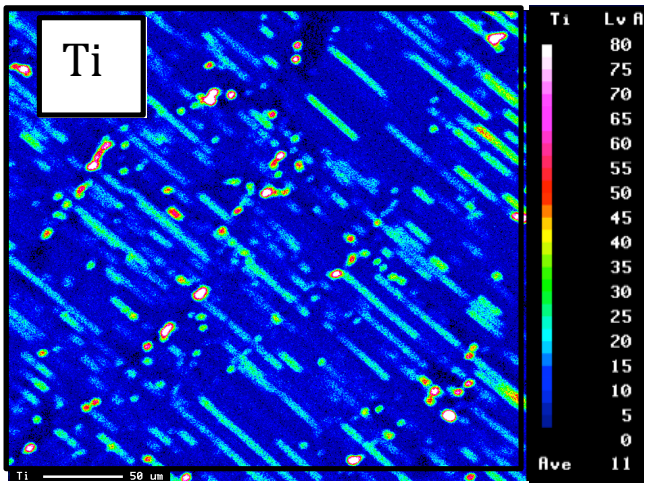
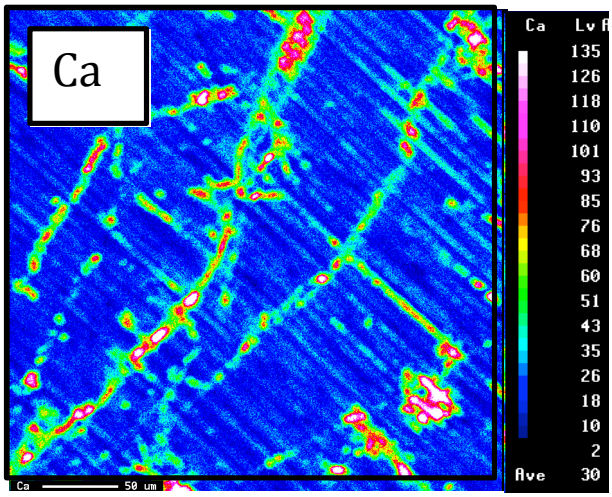
Table 2: Representative trace element composition of olivine (Ol), plagioclase (Plg), clinopyroxene (Cpx) and orthopyroxene (Opx), detail data are given in appendix part.

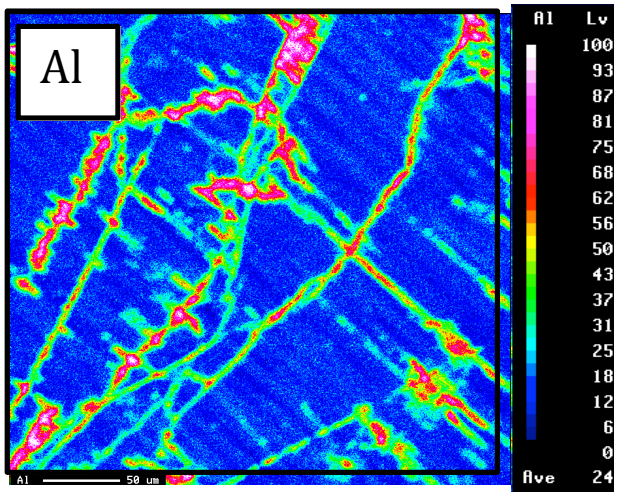
5.4. Elemental mapping of Orthopyroxene:

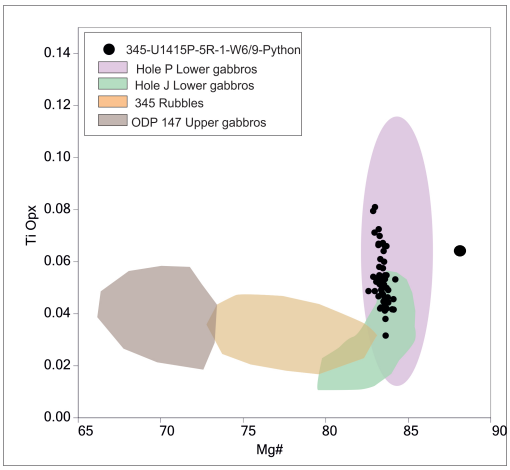
We did elemental mapping of opx in a single sample (345-U1415P-5R-1-W6/9-Python). We represent three elements mapping, Ca, Al, Ti (Fig 5.10). This one sample consist Ti 0.3-0.8%, Ca 0.15-0.6% and Al 0.18-0.32% (Fig 5.10). The enrichment zones in Al and Ca representing secondary amphibole crystallization along the fracture. Ca and Ti show enrichment lamellas. Ti rich lamellas are not corresponding to Ca rich lamellas; rather they follow the structure of orthopyroxene. Some of the points are showing enriched TiO_2, these are alteration grains. In this sample Ti have a range from 0.2-0.8, and so the higher values are corresponding to the lamella and the lower values are correspond to the background orthopyroxene.

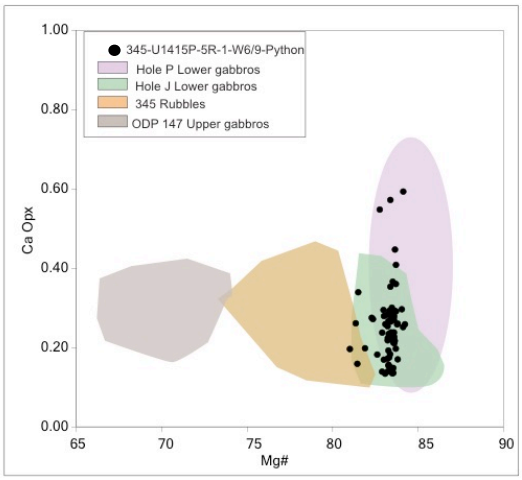












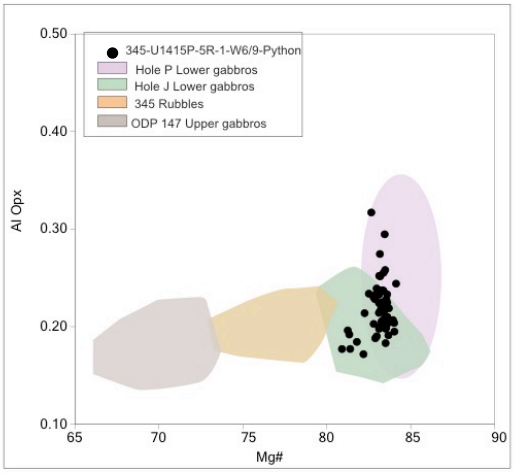


Figure 5.1. Elemental mapping of a single orthopyroxene crystal: Ti, Ca, Al considered for mapping to see the alteration pattern and signature of crystallization of Opx rather secondary precipitation. Three Variation diagram of Ti, Ca and Al vs. Mg# are the analysis of single sample where elemental mapping was performed.

5.5. Calculated liquid in equillibrium:

The distribution of major and rare earth elements (REEs) between these major rock-forming minerals and basaltic melts is important to the interpretation of origin and evolution of mafic and ultramafic igneous rocks.

Here we have calculated the liquid in equilibrium with the major mineral phases of clinopyroxene and orthopyroxene to compare their equilibrium liquid composition for troctolite, ol-gabbro, opx-ol gabbro from Hole P and Hole J; rubbles and upper gabbro.

In case of Hole P ol-gabbro and opx-ol gabbro, melt in equilibrium with clinopyroxene have TiO_2 value ranges from 0.2-3% with narrow scatter of Mg#, 60-70% (Fig 5.11 A). The higher value observed in troctolitic rock melt in equilibrium, with Mg# 70-80% and lower TiO_2 composition varies between 0.5-2%. Hole J ol-gabbro and opx-ol gabbro, TiO_2 of melt having lower concentration that is below 3% with Mg# 55-66%. Troctolitc melt covering a range of Mg# 55-70% with TiO_2 from0.3-2.2%. Like Hole J gabbros, similar concentration of TiO_2 can observed from upper gabbro sample with TiO_2 0.2-2% (Fig 5.11 B).

Hole P melt in equilibrium with orthopyroxene have very high range in TiO_2 value, from 1-7% with narrow scatter of Mg#, 50-60%(Fig 5.11 C). Hole J TiO_2 of melt having lower concentration ranges, 1-5% with Mg# 50-55%. Rubbles having TiO_2, 2-4% with Mg# 35-45%. Upper gabbros are much enrich in TiO_2, 3-5% with lower value of Mg#, 30-40% (Fig 5.11 D).

We also calculate melt in equilibrium with the REE elements for plagioclase, olivine, clinopyroxene and orthopyroxene. Hole P clinopyroxene REE melt in equilibrium, normalized in N-MORB has flat trend, with negative europium anomaly (Fig. 5.11A). Two types of melt in equilibrium with olivine can be observed. The blue lines are very enriched in terms of HREE than the main data cloud (Fig. 5.11A). Orthopyroxene melt in equilibrium has very strong Europium anomaly, with less flat trend than clinopyroxene and

having high enrichment in HREE (Fig 5.11B). Melt equilibrium with plagioclase has lower value of HREE, just reverse as olivine (Fig 5.11B).

Hole J, melt in equilibrium with REE concentration of clinopyroxene has flat trend, with almost low europium anomaly (Fig 5.11C). Opx melt in equilibrium has negative europium anomaly with slight enrichment in HREE (Fig 5.11C). Ol melt in equilibrium is also having same value as HoleP main data cloud (Fig 5.11C).

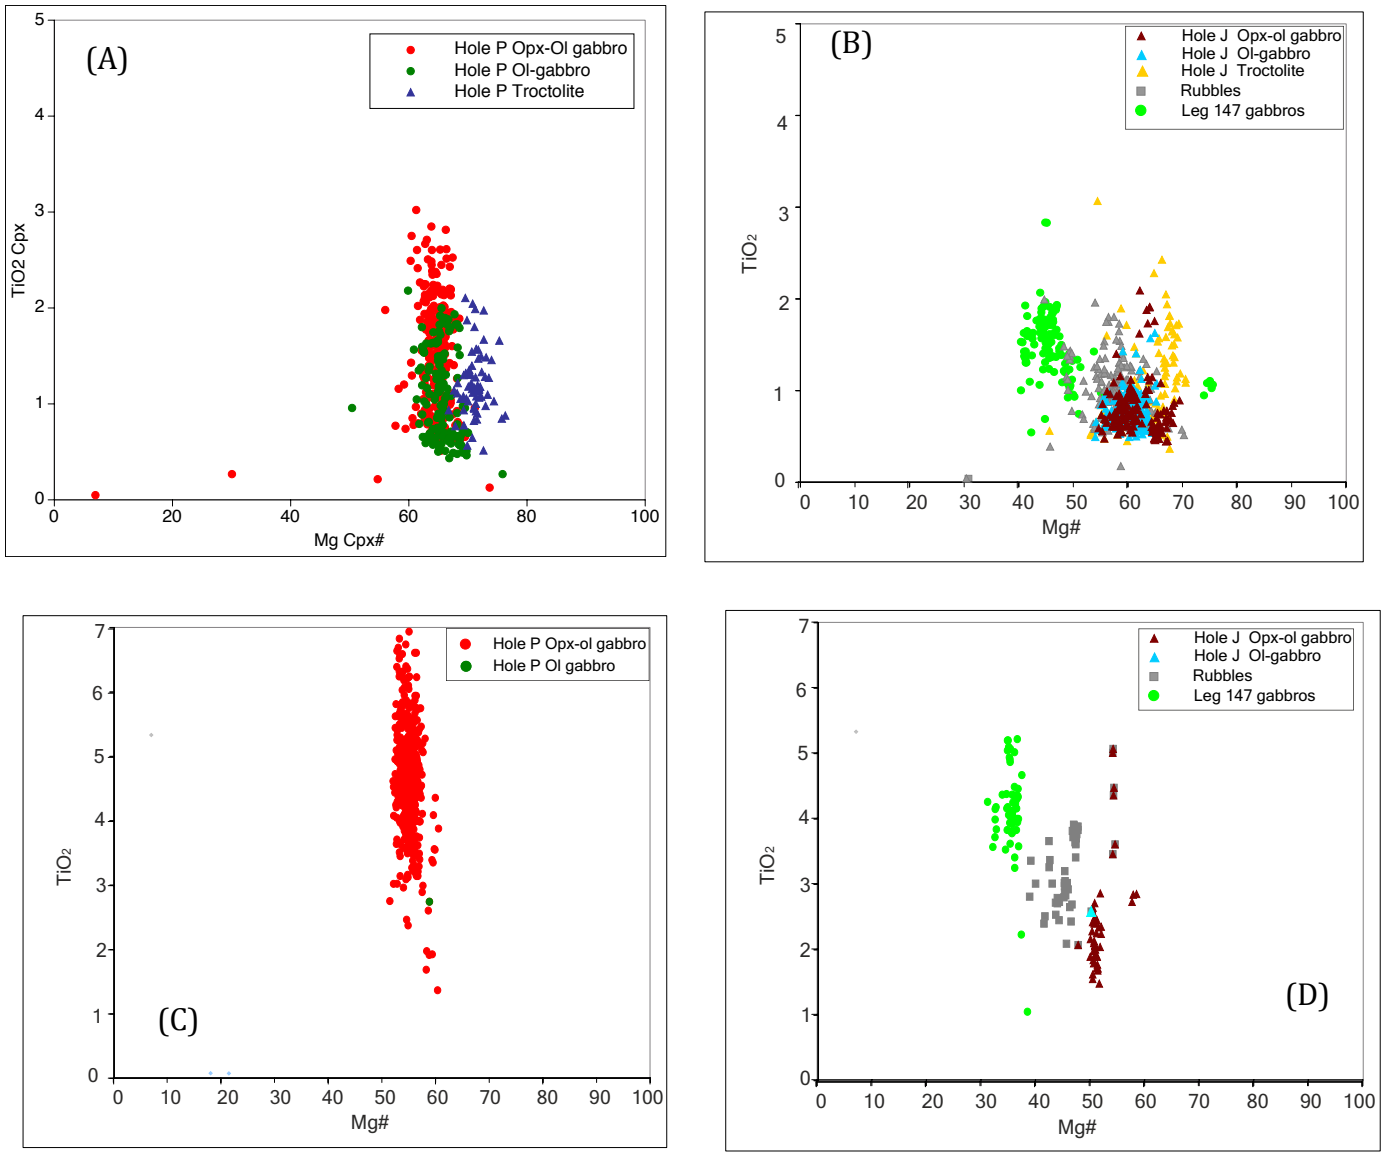

Figure 5.11: Melt in equilibrium with Clinopyroxene (A) for Hole P and (B) for Hole J; and with Orthopyroxene (C) for Hole P and (D) for Hole J using the calculation method by Bédard,2010, with the KD values of corresponding elements for particular mineral phases .

Chapter 6

6. Discussion

6.1. Petrogenesis of gabbros at EPR

6.1.1. Upper gabbros

Upper crustal gabbros recovered during Leg 147 and rubbles during IODP Exp. 345 are collected from different sites.

The upper gabbros collected during ODP Leg 147 represent the most differentiated terms of our sampling. Olivine bearing lihtologies are more primitive with a Cpx Mg# higher than in gabbronorites. Rubbles sampled at the top of Holes J and P during IODP Exp. 345 show a chemistry partially recovering Hole J and P chemical fields, and located at the most differentiated side of these zones. They globally show intermediate characteristics between upper gabbros and Hole P and J (Fig. 5.3, 5.4 and 5.6). We can then infer that rubbles are actually not fallen from the uppermost part of the crust but from some intermediate level above the lower gabbros drilled during IODP Exp. 345 and relatively close to them.

Olivine bearing sample are in every cases more primitive than olivine-free samples, the presence or absence of Opx itself and mafic minerals chemistry seem to be independent as olivine bearing samples show the highest Mg# whether Opx are present or not (Fig. 5.3, 5.4, 5.6). This point to a genesis in Opx independent from fractional crystallization process in primitive facies. Opx bearing olivine gabbros have mostly a mineral chemical composition similar to that observed in Opx free olivine gabbros (Fig. 5.3, 5.4, 5.6). Opx chemistry ranges from primitive (Mg# > 85%) in Hole J Opx bearing olivine gabbros to differentiated (Mg# < 70%) in upper gabbros gabbronorites, showing that Opx is possibly crystallizing at any step during magma differentiation in Hess Deep gabbros.

On the other hand, when olivine is absent, gabbronorites show more differentiated chemistries than gabbros. This suggests that when the magma reached the Ol-out limit, the crystallization of Opx is linked to differentiation and this mineral will appear only after the crystallization process is quite advanced and SiO_2 increased enough in the magma to allow its formation.

From liquid in equilibrium diagram (Fig. 6.4 A, B), we can see that the upper gabbros crystallized from a melt with compositions very similar to EPR MORB. Then the parental melt composition was likely a pure MORB and local crystallization processes in the magmatic mush probably acquired the scatter in Cpx and Opx chemistries.

Previous studies on upper Hess Deep gabbros showed that hydrothermal fluid flowed throughout the entire gabbroic sequence and alteration was dominated by pervasive fluid flow along grain boundaries, microfractures, and fractures. These upper gabbros show that incipient flow occurred at amphibolite facies (average temperature = 720°C) conditions and is manifested by amphibole veins that display no preferred orientation (Manning et al., 1996; Coogan et al., 2002a) and replacement of pyroxene by amphibole-dominated assemblages (Früh-Green et al., 1996; Gillis, 1995; Kirchner and Gillis, 2012). Whole-rock samples unaffected by a lower temperature stage of brittle deformation are depleted in δ18O relative to fresh values (Agrinier et al., 1995; Lécuyer and Reynard, 1996) and show minor enrichment in 87Sr/86Sr (Lécuyer and Grau, 1996; Kirchner and Gillis, 2012). Calculated fluid/rock ratios using both isotopic systems range from 0.1 to 1 (Lécuyer and Grau, 1996; Lécuyer and Reynard, 1996; Kirchner and Gillis, 2012). The rate of cooling of the shallow-level gabbros is rapid (1,000 to 60,000°C/m.y.) and comparable to the upper gabbro section in the Oman ophiolite (Coogan et al., 2007; Faak et al., 2011).

Effects of Cocos-Nazca rifting reported in the gabbros which are exposed along the intraridge rift cooled to ~450°C, they became influenced by the creating a dense array of east–west tensile fractures filled with greenschist to zeolite facies assemblages and local cataclasis cemented with the same assemblage (Früh-Green et al., 1996; Manning and MacLeod, 1996). The Cocos-Nazca rifting influence was mainly post-magmatic and influenced the cooling rate and the hydrothermal temperature. Primary magmatic processes appear to have mainly occurred at the East Pacific Rise.

6.1.2. The lower sequence (Holes J and P)

The study of the lower gabbroic section was the main purpose of this project. We will see that the gabbros from Hole J resulted from complex crystallization processes in a magmatic mush and that the chemistry of the gabbros from Hole P show the existence of an enriched mantle source beneath EPR.

6.1.2.1. Crystallization in a mush:

Textural relationships in olivine-rich gabbros indicate that clinopyroxene crystallized after a melt that was in disequilibrium with primitive plagioclase, and olivine (Fig 4.8D). However, Fe-Mg chemical equilibrium is observed (Fig. 5.5), showing chemical Ol/Cpx re-equilibration during crystallization. This is compatible with the very low cooling rate calculated by Faak and Gillis (2016). These observations suggest that the crystallization of the gabbros occurred as a multi-stage (at least two stages) process and sub-solidus re-equilibration: crystallization fo Pl and Ol, assimilation/crystallization for clinopyroxene with chemical equilibration with Ol, and subsolidus re-equilibration.

Assimilation of olivine induces changes in the crystallizing melt composition (Lissenberg and Dick, 2008). The addition of an olivine component in the melt may explain the particularly high contents in compatible and refractory elements, such as Mg or Ni (Fig. 5.3) and Mg# buffering observed in particular in Hole P Opx bearing gabbros (see following sections).

Olivine and high Mg# clinopyroxenes are in Fe-Mg equilibrium in olivine-rich rich gabbros and in neighbouring samples, in a way similar to what is described in the troctolites sampled at the Kane Megamullion (Fig. 6.2, Lissenberg and Dick, 2008). This

indicates that elemental reequilibration occurs between melts and partially assimilated minerals in the olivine-rich intervals. The continuous melt/mineral chemical reequilibration produces geochemical trends analogue to those predicted by equilibrium crystallization models, for compatible elements such as Ni. This suggests that separation of melts and minerals (both wall rock and newly crystallized grains) is slow compared to the time-scale(s) over which Mg-Fe and Ni diffusive re-equilibration occurs. This is also can be confirmed from the recrystalline texture of plagioclase (Fig 4.8 C). Also from Ce vs. An plagioclase shows increasing percentage of An in terms of Ce (Fig. 5.9 A), and has a linear relationship, which also suggests fractional crystallization of plagioclase in a system from a single batch of melt. This result is compatible with recent result obtained by Faak and Gillis (Geology, 2016) on Hess Deep gabbros, and its documented the cooling rate is $0.005\text{-}0.0001^{0}$ per year.

Figs. 5.3,5.4 and 5.6 show that Gabbros in Hole J are in chemical continuity with rubbles and upper gabbros drilled during ODP Leg. 147. Some scatter in Cpx TiO_2 content of troctolites can be explained by the low modal proportion of Cpx in troctolites. Cpx chemistry is then modified by subsolidus reaction with the modally dominant olivine or the Cpx parental melt did already reacted with olivine leading to Mg# increase before Cpx crystallization. This process can also explain Ti enrichment in some Cpx in olivine rich gabbros but Cpx chemisry is mainly constrained in a trend compatible with MORB differentiation, and the Cpx parental melt has a chemistry very similar to MORB produced at EPR (Fig. 6.5 A). This shows that Hole J, rubbles, upper gabbros are all linked to the same MORB parental melt by a fractional crystallization trend. The most differentiated terms were produced at the top section as the lower section is primitive. This general evolution is in contrast to the strong lithological diversity observed along 110m in Hole J and in the cores obtained at the top of the section (Fig. 5.1). This suggest that fractional crystallization was the dominant process in the whole column as local processes leading to

variation in the crystallization order and modal composition act in margin and led to only limited chemical variation.

6.1.2.2. Origin of olivine:

All samples from Hole J and P show high Fo value of in Olivine (Fig. 5.1 and 5.2), which suggests primitive parental melt (Fo content always over 80). The most primitive samples shown on the plot Olv Fo vs NiO are troctolites in Hole P (Fig. 5.3A). Opx bearing lithologies show a narrow scatter of olivine Fo, between 83 and 85% and are regrouped after troctolites, which is also a lower value than what is observed in troctolite, but still very high for Opx-bearing gabbroic cumulates.

We found two groups types of olivine in Hole P: when the liquid in equilibrium of REE elements is compared with EPR MORB (Fig. 6.1). Some Ol are very enriched in HREE and are out of the main cloud. They are subrounded in shape, showing resorption figures and are then probably left from an original rock after extensive melt-rock reaction. These olivines may be relics of mantle as it was suggested by previous research (Drouin et.al 2009) on Atlantis Massif. However, in the case of Hole P olivines, subrounded crystals do not show any deformation structure, like subgrain boundary or kink band. Moreover, olivine richer in HREE have a rather low Fo content (Fig. 5.8), which is in contradiction with a mantle origin. On the other hand, their chemistry is very similar to olivine chemistry in the troctolites layer located right below the gabbros (Akizawa et al, unpublished data) suggesting that they may be relic from troctolites rather than peridotites. Other olivine from the major group, show a melt composition compatible with MORB and in equilibrium with Cpx and Plg. These olivines are present as various texture, from subrounded to skeletal.

Olivine from Hole J have a chemistry very similar to EPR MORB, and are also in equilibrium with other minerals (Fig. 5.4 and 5.8).

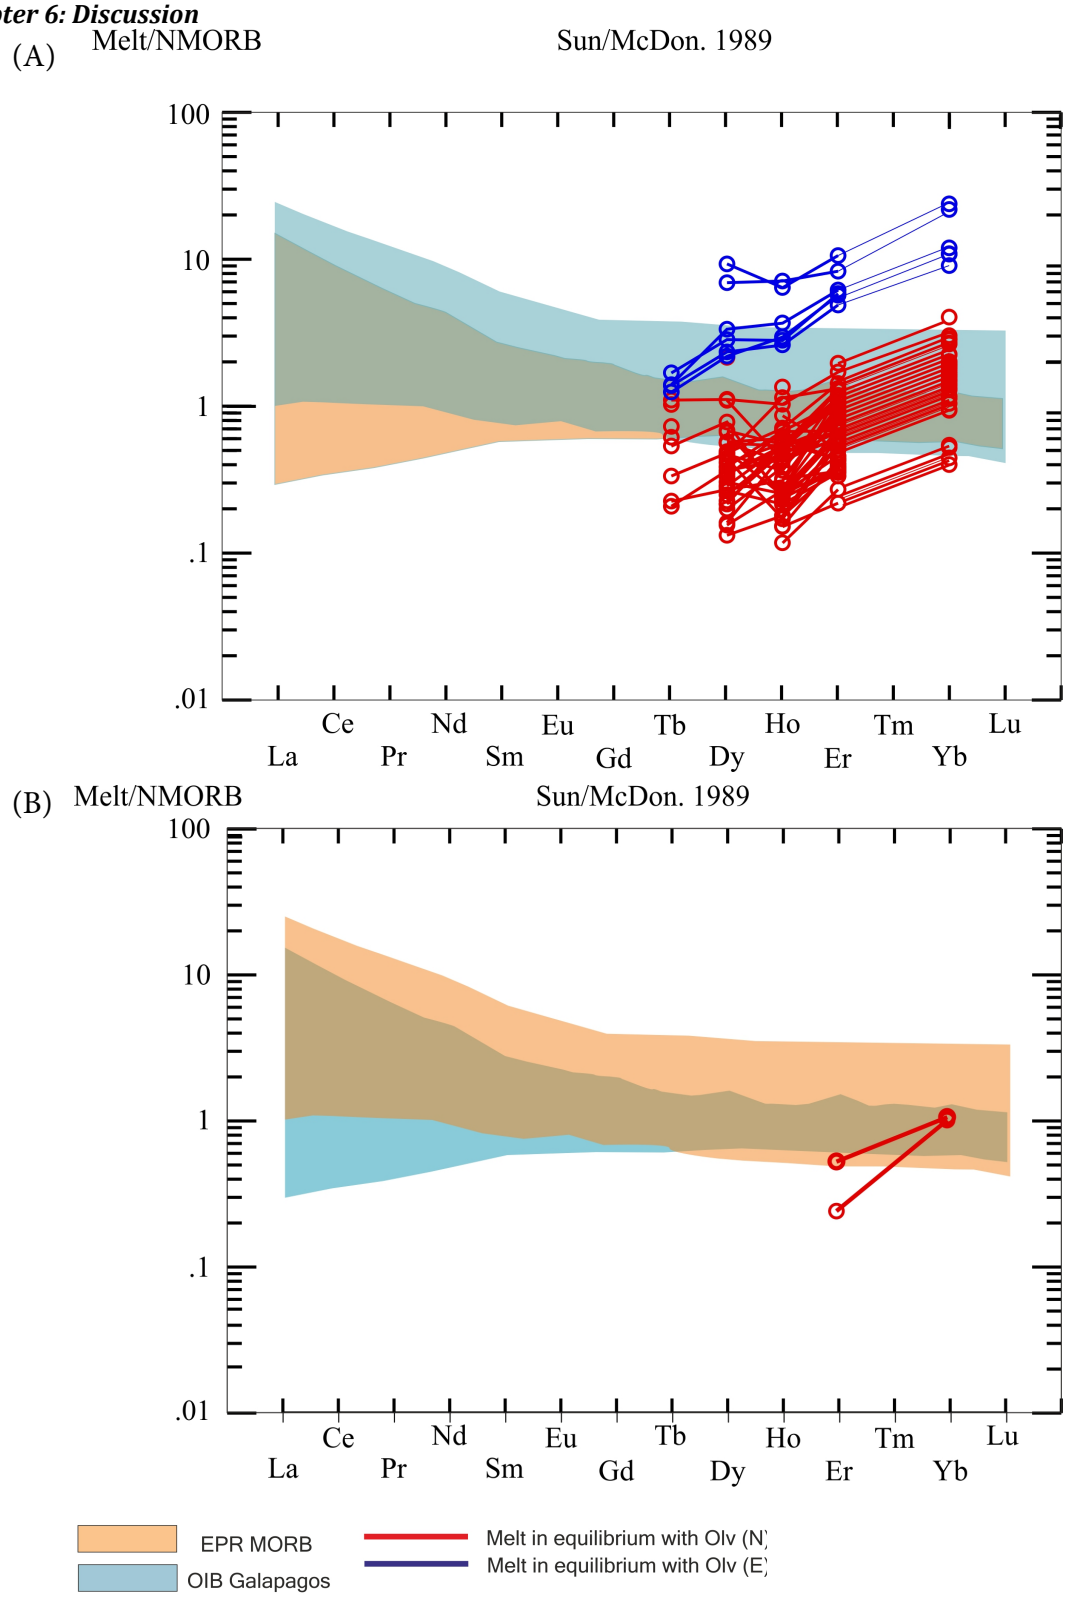

Figure 6.1 Liquid in equilibrium of REE element of olivine in Hole J (A) and Hole P(B) the blue line marked as enriched type and red line as main data cloud.

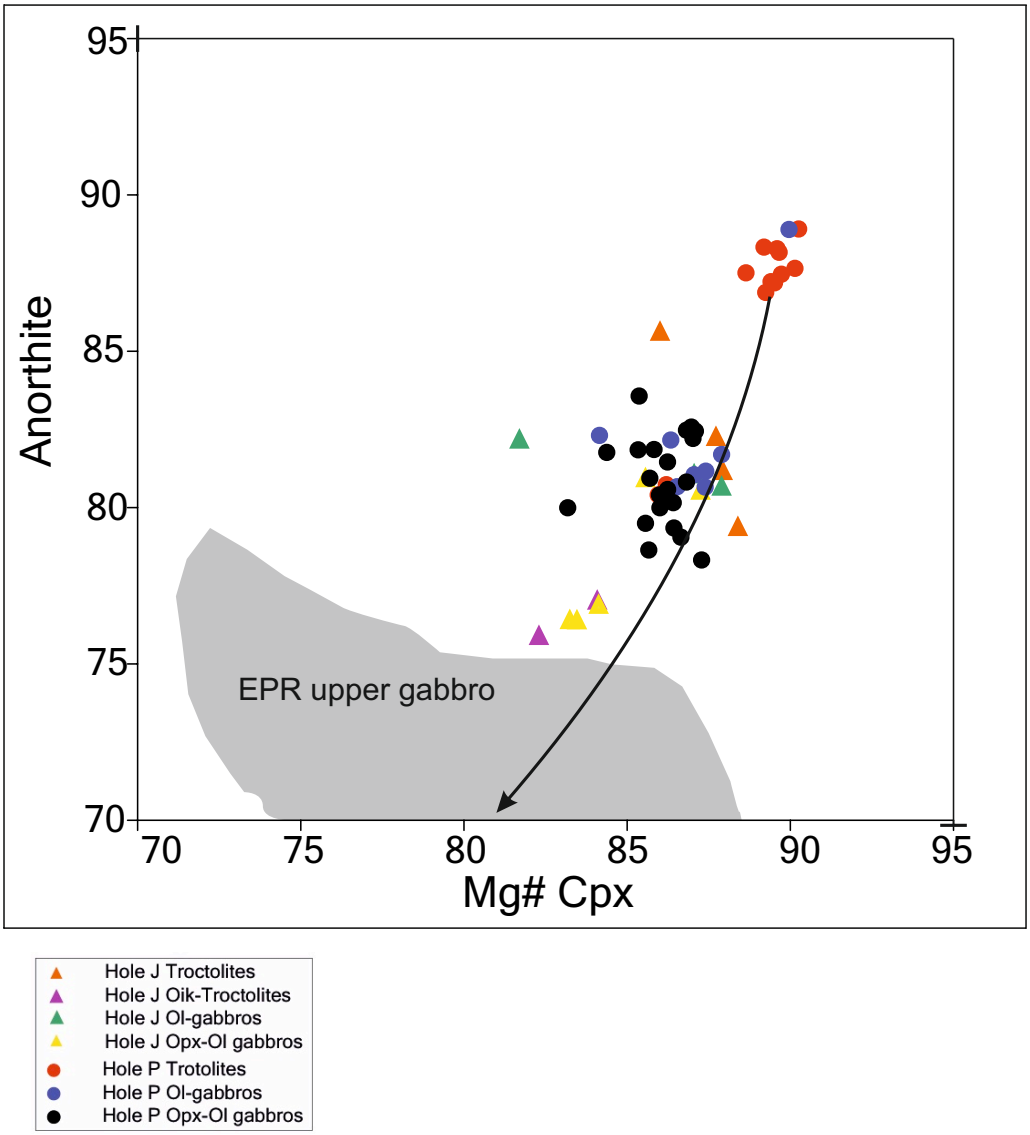

Figure 6.2. An vs. Mg# Cpx from Different holes and different rock types showing evolution trend of Hole J gabbros towards EPR MORB)

6.1.2.3. Hole J:

The downhole variation of olivine gabbro of Hole J, which detailed section is given in Fig. 5.1, show a pronounced differences between mineral compositions from rocks located at the top and at the bottom of the section. The differences between Mg# are pronounced in Cpx, Opx, Ol, and the anorthite content of Plg between gabbros located at the bottom of the section and those at the top. Mineral chemistries show a relative trend with Olv, Cpx and Opx Mg# decreasing with depth. The concentration modal proportion of Opx in Hole J is very less low compared to Hole P (less than 2%). The large chemical scatter observed in Cpx can be the expression of their presence as chemically zoned oikocryst throughout Hole J.

The petrographic observations show that the crystallization sequence starts with Ol+Plg then Cpx crystallizes into system. The poikilitic texture of most of the Cpx showed that they probably crystallized late from some kind of trapped melt. Orthopyroxene in Hole J is present in few samples at low modal percentage.

Olivine Fo content is higher in Hole J samples than in upper gabbros, but are much evolved than Hole P gabbros. In the variation diagram showing of olivine Fo vs NiO (Fig 5.3), shows a continuous evolution trend from Hole J gabbro to upper gabbro, suggesting a continuous differentiation link from the bottom to the top of the section. The variation in TiO_2 with Mg# in Cpx and Opx chemistry shows same results, with variation in Mg# with TiO_2 concentration (Fig. 5.4, 5.6). The plot anorthite in Plg vs. Mg# in Cpx shows that Hole J gabbros are located in a trend of fractionation from the troctolites towards EPR upper gabbro (Fig. 6.2) and have then an intermediate composition between primitive and differentiated crustal lithologies. The chemical evolution with depth of Ol and Plg suggest that upper, lower and intermediate gabbros are globally linked by a fractional crystallization trend and local dispersion is probably local crystallization processes leading

to the formation of the last crystals. Poikilitic Cpx are zoned and represent the last magma crystallizing during the last steps of cooling..

Fo content is higher in Hole J samples than in upper gabbro. The variation diagrams showing olivine Fo vs NiO (Fig 5.3) and Cpx/Opx chemistry (Fig. 5.4 and 5.6) show an evolution trend from Hole J gabbro to upper gabbro, suggesting again a global MORB fractional crystallization trend from Hole J to upper gabbros.

Liquids in equilibrium with Cpx and Opx (TiO2 vs Mg#, see Fig. 6.3 and 6.5) show that the melts in equilibrium with Hole J gabbros had the same composition as EPR MORB. The REE pattern for all the phases shows also compositions comparable to with EPR MORB. Hole J gabbros are then in equilibrium with the most typical MORB melt emitted at EPR. These observations suggest that the parental melt was a MORB type melt, and that the gabbros formed by crystallization in a magmatic mush largely in equilibrium with MORB and that the chemical variations in the various crystals from sample to sample are probably due to large scale fractional crystallization process, whereas the scatter within one single sample is inherited from local crystallization processes after closure of melt migration within the mush.

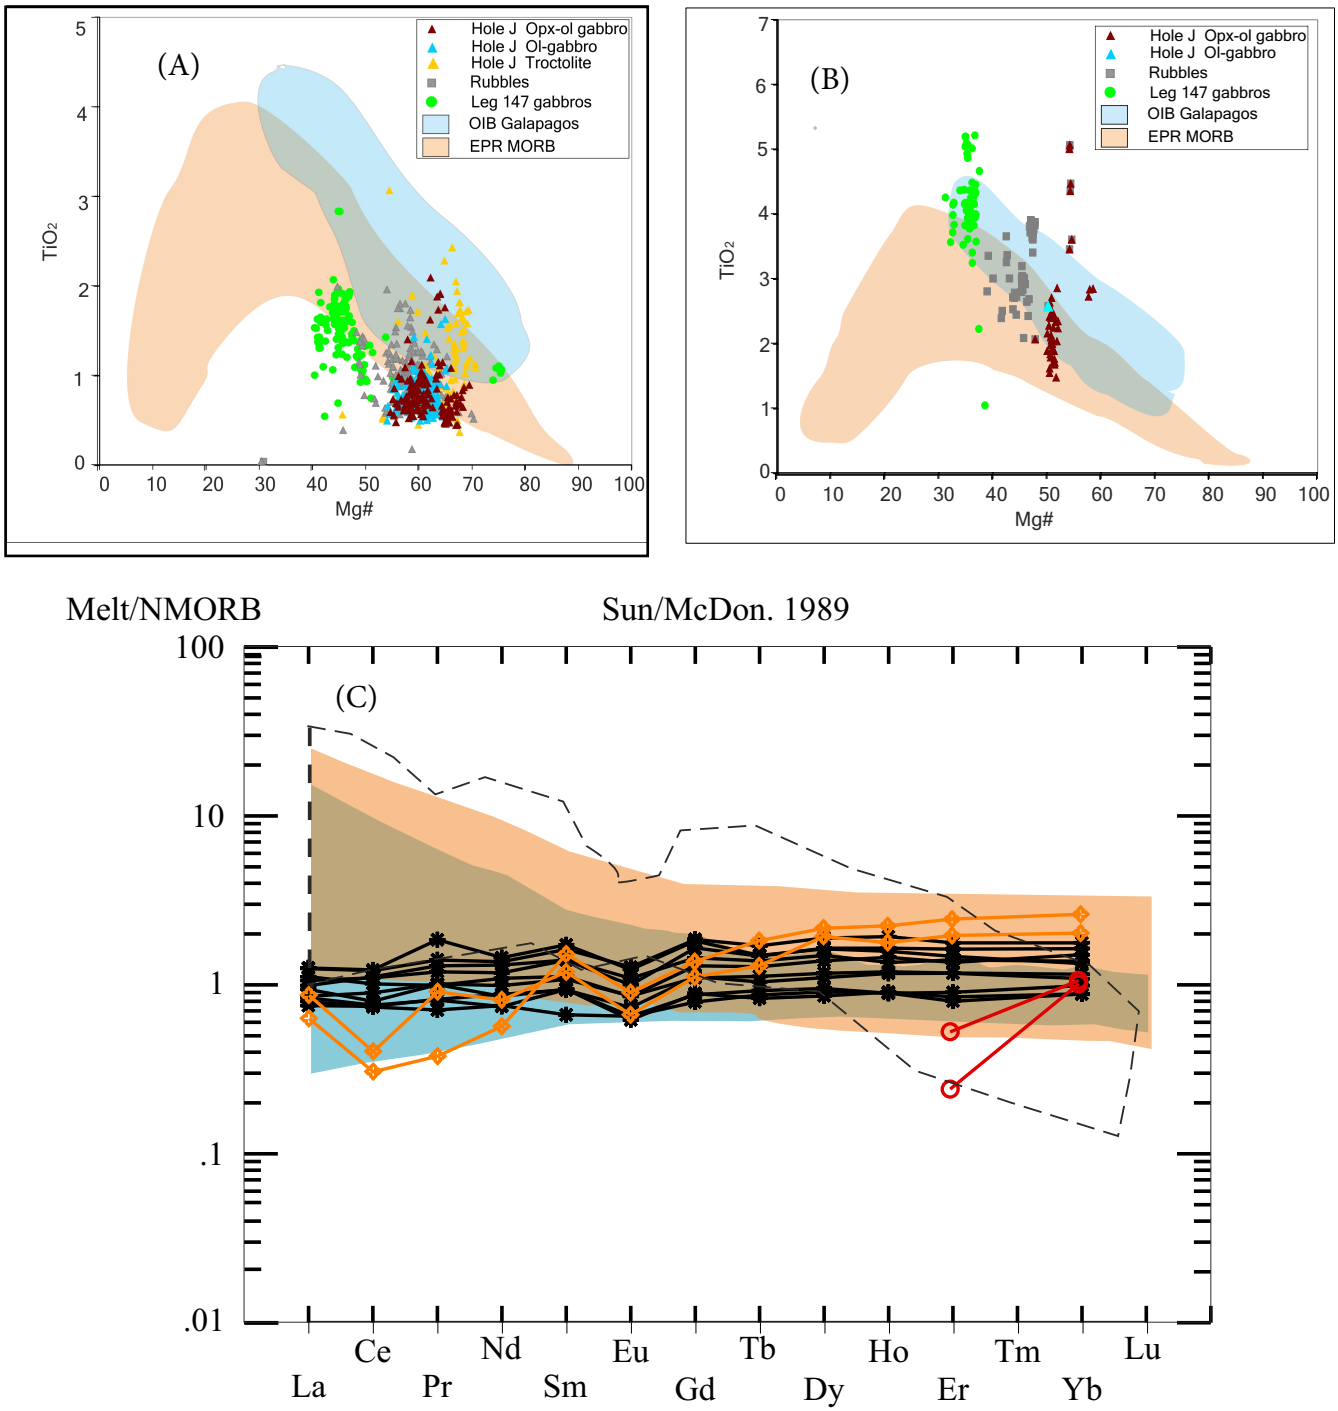

Figure 6.3. (A) Liquid in equilibrium of TiO2 vs Mg# for clinopyroxene and orthopyroxene in A and B respectively (B) Liquid in equilibrium of REE element for clinopyroxene, olivine, orthopyroxene and plagioclase in comparison with EPR MORB and OIB Galapagos type melt

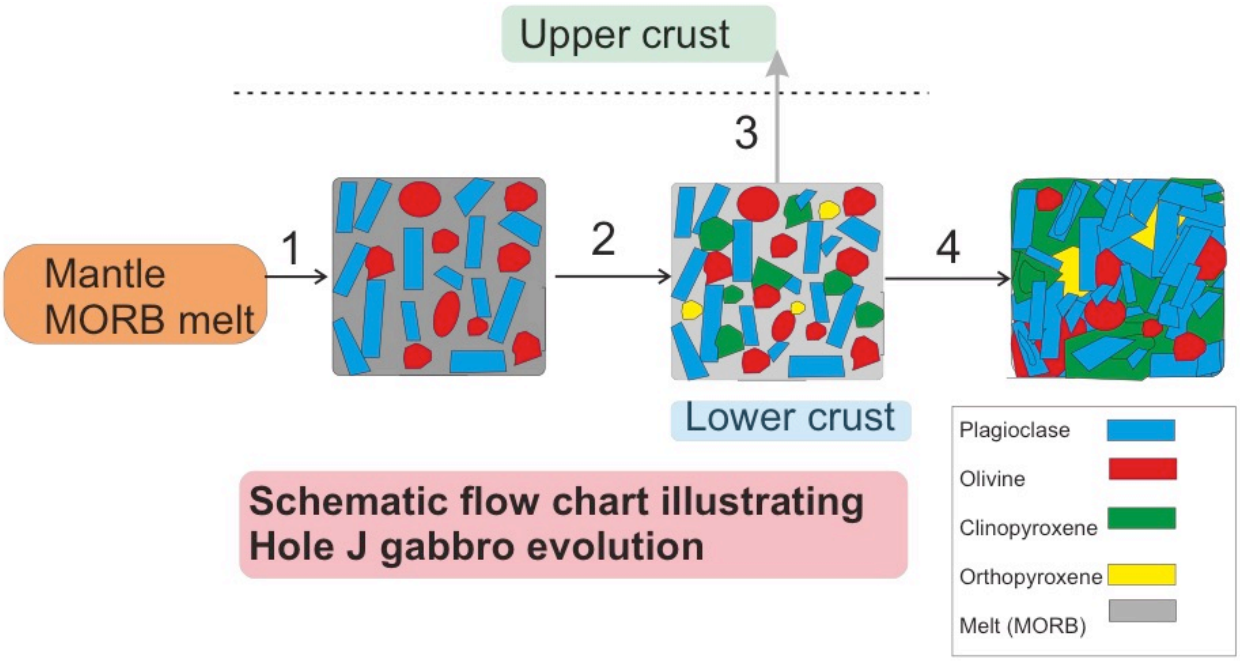

Figure 6.4: Evolution model of the Hess Deep lower crust: Hole J. First Fractional crystallization OF morb type melt form a mush, with crystallization of olivine and plagioclase, then thr gabbroic mush continue crystallization with nucleation of clinopyroxene and orthopyroxene. At this stage some melt may be extracted out to the upper crust and at last stage orthopyroxene and clinopyroxene crystallize as poikilitic texture.

6.1.2.2. Hole P:

The chemical evolution with depth for the main mineral content in Hole P shows is linked to the presence of two contrasted lithological series (Fig. 5.2). The first series was drilled from the bottom to about 70 mbsf, it is composed of troctolites with variable modal amount of olivine. Its chemistry is primitive, with high Mg# for mafic minerals, and high An content in Plg. Above 70 mbsf, olivine gabbros and Opx-bearing olivine-gabbros make the second series. Although it is represented by Opx bearing lithologies which is less primitive than troctolite and exhibit lower Mg# in mafic minerals and lower An content in Plg, mineral chemical characteristics are still quite primitive. Anorthite content in Plg is more scattered in the Opx bearing lithology gabbros than in troctolites, which points to stronger zoning in Plg in the gabbros. Two different vertical Mg# trends corresponding with the two series show that if Mg# is linked with the lithological facies, there is no clear evolution of the differentiation degree with depth within a given lithological facies (Fig. 5.2). The narrow Mg# scatter in a single sample for Ol and Opx suggest that the magma was Mg/(Mg+Fe) buffered for the formation of these minerals. In contrast the wider scatter for Cpx outline a stronger zoning for this mineral probably in relation to its textural appearance as poikilitic crystal. Local and late crystallization processes probably affected Cpx during the final stages of crystallization. In the Opx bearing gabbros the highest Opx Mg# are observed in the uppermost 20 m, together with higher TiO_2, Cr_2O_3 and Al_2O_3 content. This suggest that a rather primitive magma was present at the top of the section, whether directly injected or resulting from the reaction of the magma in the magmatic chamber with primitive walls.

Orthopyroxene and clinopyroxene both have high concentrations in Cr, Al and Ti along with high value of Mg#. These concentrations are higher than what could be expected from the fractional crystallization of a MORB melt (Fig. 5.2 B). Spinel TiO_2 vs Fo content of the coexisting olivine show that melt-rock reaction clearly occurred in association with

fractional crystallization (Fig. 6.5 D). Dick and Natland (1996) showed that melt-rock reaction predominated in Hess Deep troctolite crystallization. Fo value for Ol is buffered around 87-88% as mantle value is around 90-91%. They deduced that mantle-melt reaction led to some drop together with buffering in Mg#. Moreover, the presence of inherited olivines from a mantle slab in oceanic deep troctolites has already been described at Atlantis Massif (Drouin et al. 2009 and Suhr et al. 2008). Troctolites located at the bottom of Hole P show similar value for Ol forsterite content and no evolution with depth (around 87-88%, see Fig. 5.2), pointing to a similar formation dominated by melt-rock reaction involving a MORB melt and mantle wall rock. However, Fo value for olivine in Opx-bearing gabbros is buffered at lower values, between 83-86%, which seems to indicate a more differentiated buffer. Moreover, olivine show no deformation texture like kink band, suggesting that they originally crystallized from a melt and were not inherited from mantle. However, subrounded shape clearly shows that olivine resorption and melt-rock reaction did occur during Opx bearing gabbro formation and explain the Mg# buffering for all mafic minerals.

The trace element content in some olivine is enriched in HREE (Fig. 6.1) and show significant differences with the main composition in other olivine which is about one order lower. This olivine show subrounded texture that may have been acquired by a certain degree of resorption resulting from the reaction with a melt. HREE content in Ol does not show any significant evolution with its Fo content (Fig. 5.9), which is compatible with the crystallization from a buffered melt, however the highest HREE content are observed in olivine with rather low Mg#. The relatively low value in Fo (in comparison with mantle values) and high HREE concentration in the most differentiated olivine seems to rule out a possible mantle origin for resorbed olivines. On the other hand, the chemistry of enriched olivine is very similar to that of olivines from the troctolite layer located below the Opx-bearing gabbros in Hole P (Akizawa et al., personal communication). This points to a

possible troctolitic buffer and olivine inherited from troctolite after melt-rock reaction during the formation of Opx-bearing lithologies above the troctolite layer. This hypothesis is also compatible with the large Mg# scatter in Cpx and An scatter in Plg, those minerals being partly crystallized in the troctolites before being reacted with the Opx-bearing gabbros parental melt.

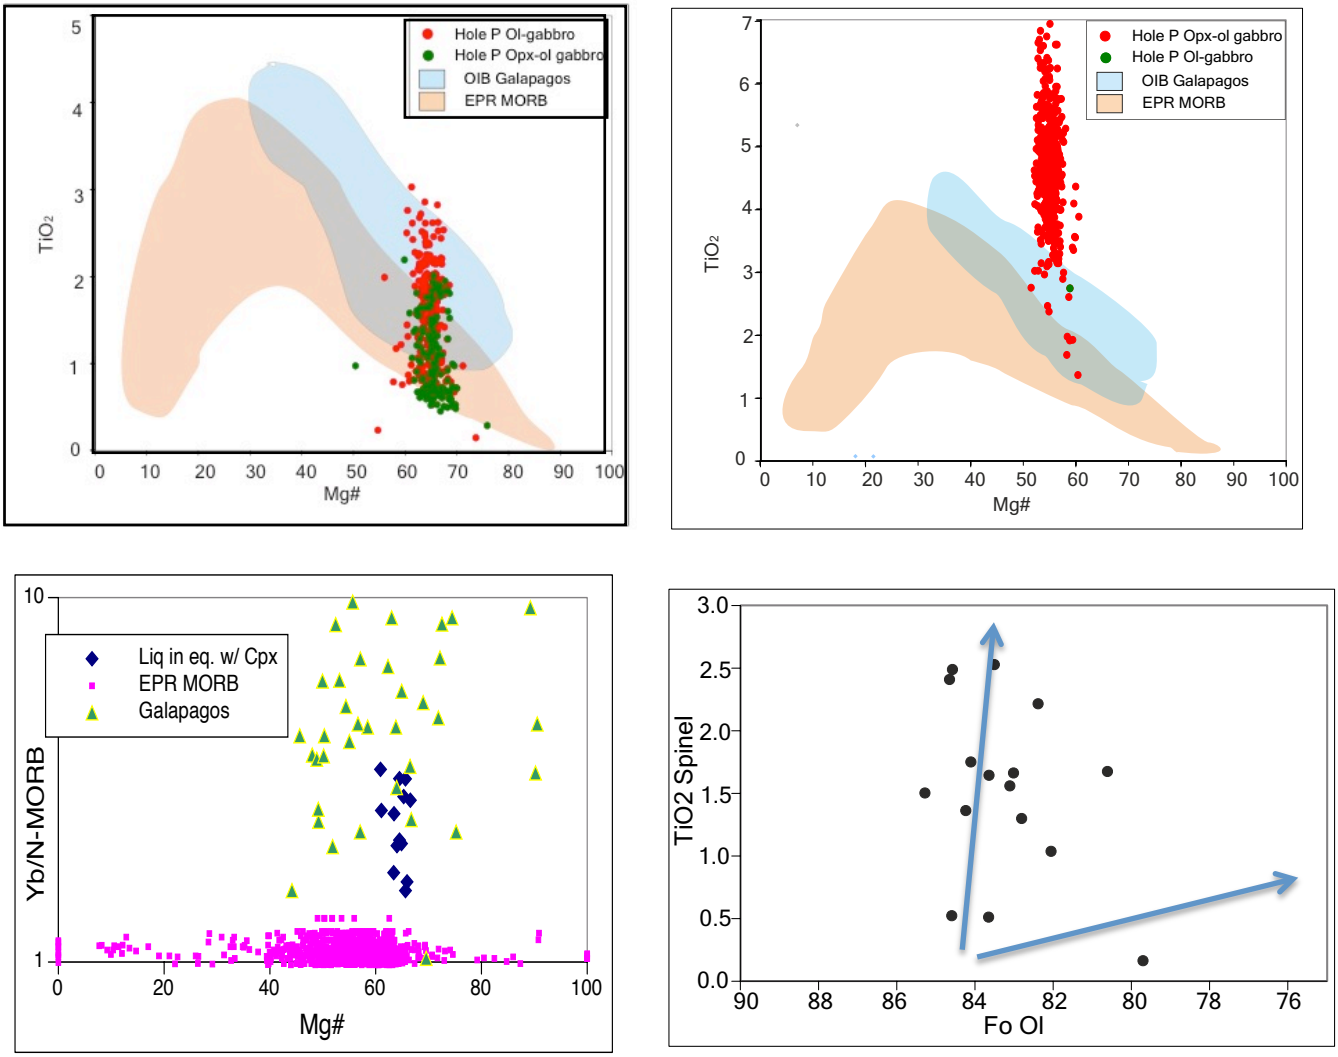

Figure 6.5 Liquid in equilibrium of TiO2 vs Mg# for clinopyroxene and orthopyroxene in A and B respectively, (C)Liquid in equilibrium with Yb comaperd with EPR MORB and galapagos glass (D) Hole P gabbros, Weight percent TiO2 spinel plotted against the forsterite content of coexisting olivine. Shown for comparison are the approximate trends for meltrock reaction, where Mg# is buffered, and without fractional crystallization (Dick and Natland, 1996)

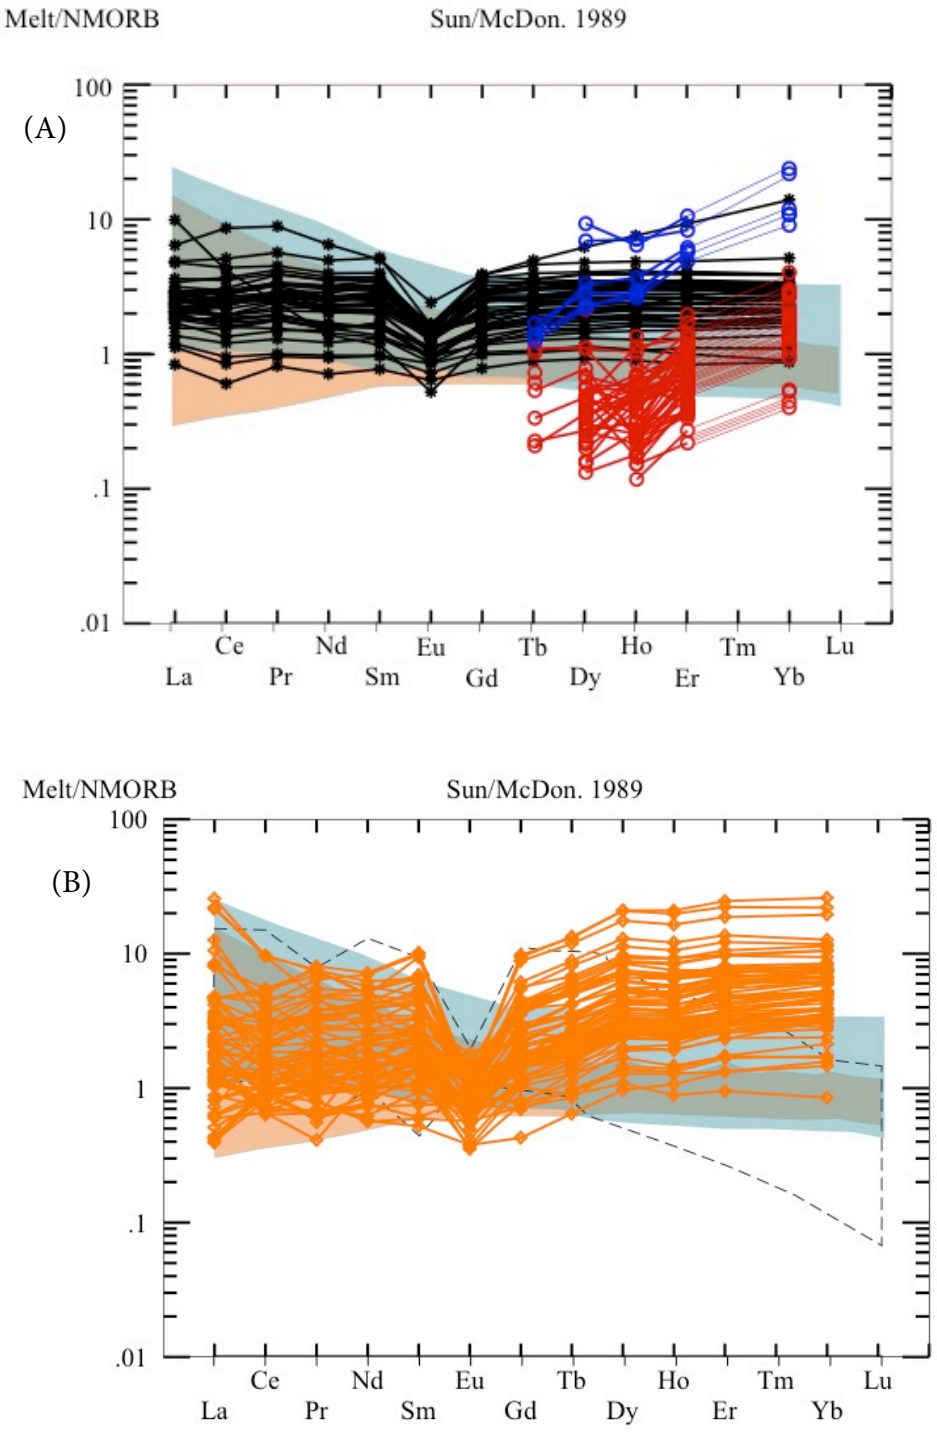

Figure 6.6. (A) Liquid in equilibrium of REE element for clinopyroxene and olivine and (B) orthopyroxene and plagioclase in comparisons with EPR MORB and OIB Galapagos type melt

6.2. Enriched component in mantle source:

Melts in equilibrium with gabbros from Hole J show a MORB like chemistry making a continuous trend with the melts in equilibrium with upper gabbros (Fig. 6.3). In Hess Deep lower gabbros, Cpx occur as oikocrysts that enclose, and therefore overgrew, early crystallized olivine and plagioclase. Cpx are then precipitated as late interstitial grains between olivine and plagioclase. This indicates that gabbro crystallization followed the normal fractionation trend for MORB, with clinopyroxene saturation following olivine+plagioclase.

In Hole P gabbros, the poikilitic texture of Cpx outline a high temperature crystallization where Ol and Plg co-crystallized and pyroxenes came later and where trapped in melt pockets. Orthopyroxene occur as poikilitic, prismatic and interfingered with Cpx. Thus Opx crystallized together with Cpx but sometimes slightly earlier as shown by the existence of prismatic Opx included in poikilitic Cpx. High pressure early clinopyroxene fractionation would lower the Mg# of the melt significantly by the time it saturates in plagioclase, leading to lower clinopyroxene Mg# at a given plagioclase anorthite content. Finally, the TiO_2 and Cr_2O_3 contents of the oikocrysts differ from those expected from fractionation of a MORB melt (Fig. 6.5). The melt in equilibrium with the oikocrysts has TiO_2 concentrations as high as evolved melts in equilibrium with MORB but a primitive Mg#. On the other hand, Orthopyroxene also has higher Mg# and extremely high TiO_2 content. In a MORB crystallization sequence, orthopyroxene crystallize late and should have lower Mg#, higher incompatible elements concentrations. In Hess Deep gabbros however, Cpx and Opx Mg# stay in the primitive range. The TiO_2 and REE contents largely exceed any values obtained by differentiation from MORB or OIB enriched melts (Fig. 6.5). The chemistry of the melts in equilibrium with Cpx is in between the MORB and Galapagos OIB chemical domains. On the Other hand, TiO_2 and REE concentrations in the melts in equilibrium with Opx exceeds the highest values recorded in Galapagos

enriched melts, even the most differentiated (Fig. 6.5). This indicates that the clinopyroxene and orthopyroxene could not have been produced by extensive fractionation of a MORB under equilibrium conditions. High TiO_2 and REE contents of the parental melts indicate an enriched source for Hole P Opx-bearing gabbros.

The two main candidates for the enriched source are:

1- Deep mantle enriched source coming from the Galapagos hot spot and contaminating EPR westward to Hess Deep;

2- An eclogite-pyroxenitic source present in the mantle below EPR at the time of Hess Deep gabbros genesis.

A weak degree of contamination from the Hawaii hot spot was detected in EPR basaltic glasses (Niu et al.,1999) but Hess Deep basalts seems to be of purely MORB nature without any chemical evidence of enriched melt (Batiza et al, 1992). Primitive melt from hot spots has enriched chemical characteristics that make a good candidate for the mixing melt and a contamination by the relatively close Galapagos hot spot cannot be totally excluded. However, geophysical data showed that the Galapagos plume tends to migrate southward and gets away from any potential Hess Deep source (Villagómez et al. 2014). The ubiquitous presence of Opx in Hole P gabbros, as well as olivine resorption textures, suggest that the enriched melt was rich in Si. The high Mg# of all mafic minerals is an evidence showing that this melt was also primitive. High-Si primitive melt are likely to be formed by the melting of pyroxenite as, on the other hand, picritic olivine-saturated melts should be emitted from the melting of a deep mantle source. Thus, in Hess Deep gabbro case, a pyroxenitic source was probably present in the mantle 20 Ma ago.

6.3. Origin of Orthopyroxene

We have already seen that Opx bearing gabbros in Hole P crystallized from a melt buffered in Mg# by reaction of a MORB melt with the crystallizing underlying troctolite, this process leading to enrichment in Ti, Cr and Al. Whereas orthopyroxene in Hole J has a lower modal abundance and a very comparable chemical signature with EPR MORB. Evolution of Opx chemistry with depth in Hole P (Fig: 5.2) show that large scatters are observed for TiO_2, Al_2O_3, Cr_2O_3 as one single sample cover about the whole range of concentration (Fig. 5.10). In accordance with the slight increase in Mg# at the uppermost 20m, TiO_2 slightly decreases and Cr_2O_3 and Al_2O_3 increase. Cr_2O_3 significantly increase at the top section. Which also implies more enriched melt injection in the upper section.

Opx elemental mapping shows enriched zones in Al and Ca representing secondary amphibole crystallization along Opx fractures and some Ca-rich exsolution lamellas, corresponding to slow cooling event (Fig. 5.10). Ti rich lamellas are also present and are parrallel to the Opx crystallographic structures but do not correspond to the Ca rich lamellas, implying that they are not related to Ti local enrichment due to exsolution during cooling but are more probably of magmatic origin. The origin of these Ti-rich lamellas are puzzling, as it is unusual for magma inherited chemical characteristic to be included within exsolution-like structures. It is possible to imagine that small increment of Ti and Si-rich magma, produced by the melting of the pyroxenitic source, may have been injected in the crystallizing mush, leading to a enrichment pic in Ti while increased Si would put the magma on the Opx cotectic leading to the sporadic crystallization of unusually Ti-rich Opx. However, instead Ti diffusion rate is quite slow, subsolidus exsolution cannot be excluded without detailed crystallographic study. It has to be noted that out of the Ti-rich lamellas, the TiO_2 average content in Opx (blue background in Fig 5.10, and see Fig 6.7 for Opx average composition) is still higher than any Opx crystallizing from Galapagos or MORB magma could be.

The generation of Opx in Hole P is driven by melt-rock reaction process buffering the Mg#; mixing of MORB with an pyroxenitic enriched melt leading to enrichment in Ti, Cr and Al; and crystallization in a mush leading to the formation of poikilitic Cpx and prismatic to poikilitic Opx.

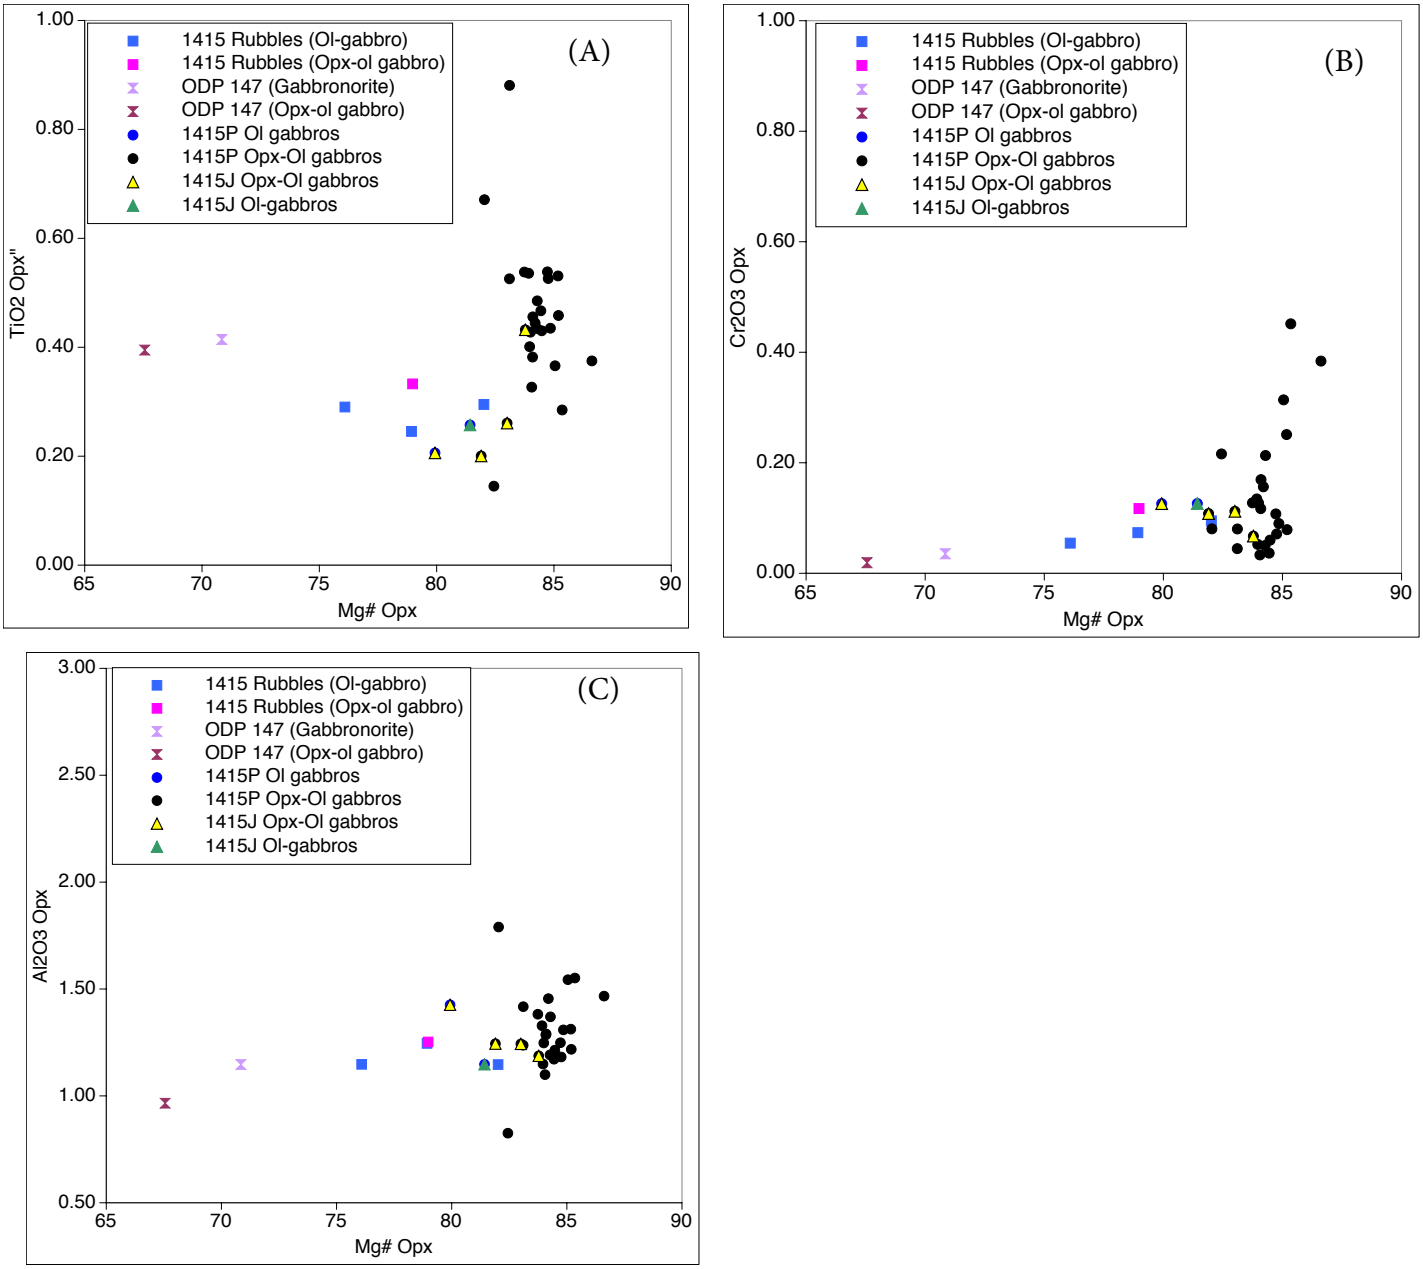

Figure 6.7: Average Opx chemistry for each samplse from upper gabbros from ODP Leg 147, rubbles from Exp. 345, Ol-gabbro and Opx-ol gabbro from Hole U1415J and Hole U1415P (A) TiO_2 vs.Mg#, (B) Cr_2O_3 vs Mg# (C) Al_2O_3 vs. Mg#

6.4. Non-Extracted melt from lower crust:

Previous studies showed from petrological and geophysical evidence that two paired magma lenses are present at two levels beneath the East pacific Rise. The first is located about 1.5 km below the sea floor, its existence was already shown by seismic reflection techniques nearly three decades ago (e.g., Ludwig et al., 1980; Herron et al., 1980). It is widespread and considered to reside just beneath the base of sheeted dikes (Kent et al., 1993), it is emitting all the magma that is expressed at the surface and that makes the basaltic layer. The location of the upper melt lenses at fast-spreading ridges is controlled by a permeability barrier, the barrier blocks upward flow of buoyant magma and corresponds to a conductive boundary layer (Natland and Dick, 2009). Cracking under over-pressure in the magma lens is the only process which can allow the melt to be extracted from the lens.

Seismic refraction results published by Garmany (1989) showed that the lower melt lens is located at the base of the crust, just above the mantle. This result was later confirmed using compliance techniques by Crawford et al. (1999). These studies showed that both lenses are thin (50–100 m), narrow (1–1.5 km), axially centered, and mostly molten. The rocks in between the two lenses are nearly solid, with no more than 2.5–18% melt, at least at the time the geophysical experiments were conducted - the variance depending on model parameters (Natland and Dick 2009). This lens will emit almost no magma in the upper crust but rather form primitive olivine-rich gabbros in-situ. The non-extraction of magma from the deep lens would be explained by it picritic composition. Picritic magma are heavier than a MORB melt crystallizing gabbros and then sink below the MORB mush (Natland and Dick 2009).

At the time of Hess Deep gabbros genesis, the melting of a pyroxenitic source below EPR would lead to the emission of a primitive Ti, Cr and REE enriched primitive melt. This

melt is richer in Si and then lighter than MORB or picritic melts. However, it is also more viscous and is less likely to be extracted from a crystal-rich mush. The pyroxenitic melt would then contaminate the picritic melt lens, which is rich in olivine and crystallizing troctolite. The contamination would lead to increase of Si content in the interstitial magma, pulling it out of the olivine stability field and in the enstatite field. Opx then crystallize as Ol is progressively resorbed. These two processes act in a reverse way than the contamination, the resorption of Ol and crystallization of Opx lowering the Si content of the magma, Ol will be a liquidus phase and then crystallize again. Incremental contamination by several injection events would move the chemistry of the magma over the Ol-Opx stability field boundary and allow concurrent crystallization of both phases in an environment buffered in Mg# thanks to the high concentration in olivine of the starting picritic melt. Each batch of pyroxenitic melt will lead to pic enrichment in Ti, Cr, REE that are expressed in the enriched lamellas in Opx.

Here it is noted that the composition of Hole P, Cpx show chemistry inherited from this mixing process, while the Hole J and the upper gabbros chemistry can be explained by pure crystallization from a MORB. In other hand Hole P Opx shows very different characteristic, we can assume that as late crystalline phase Opx crystallize from more differentiated and chemically buffered melt that react with the crystalline mush. Only 200m away Hole J Opx shows different chemistry and can be formed by crystallization from a MORB melt.

So either the gabbros acted as a significant chemical and physical filter preventing the contaminated magma to rise up to the basalts, or other process resulted in the blockage of some magma fractions in the deeper crustal level.

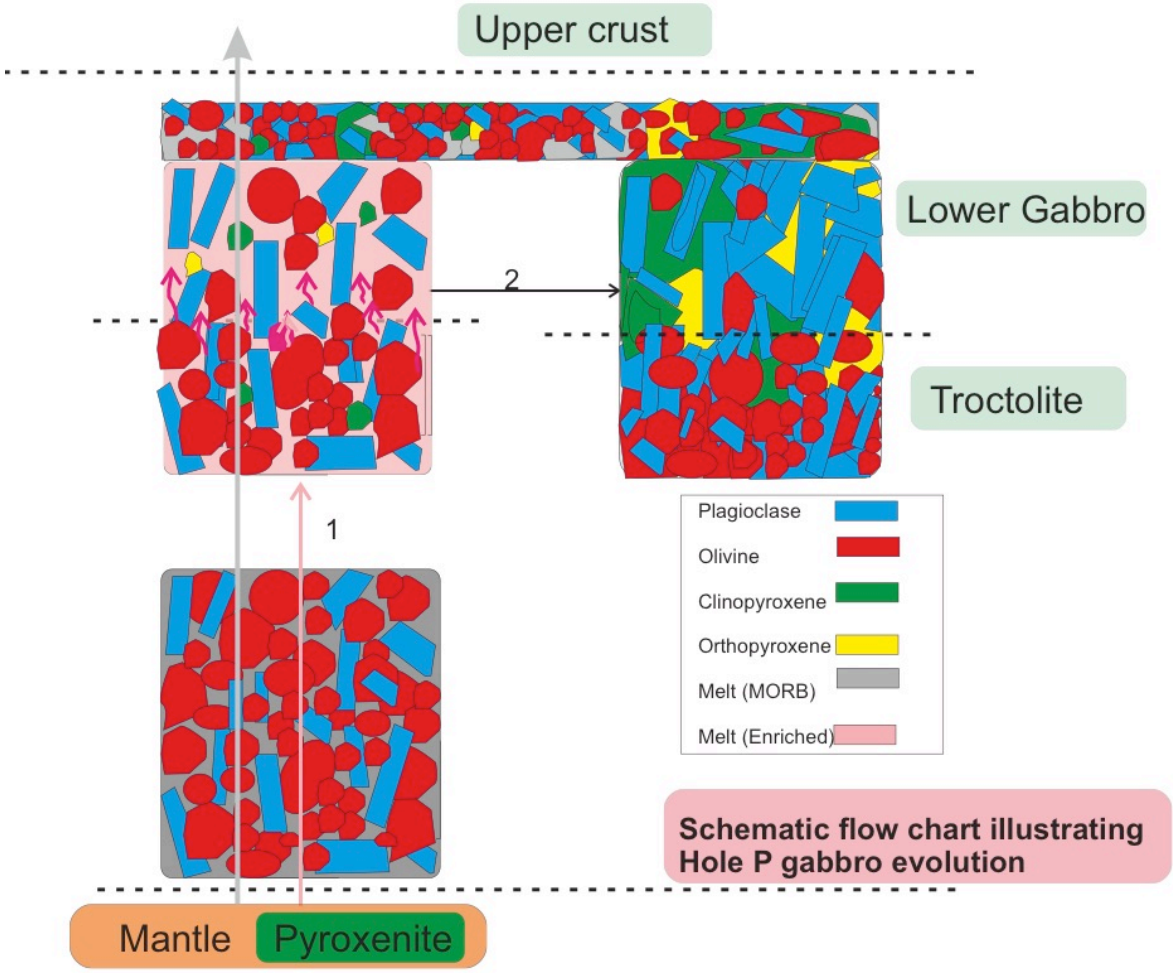

Figure 6.8: Evolution model of the Hess Deep lower crust: Hole P . First crystallization of a troctolitic mush with high Mg#, then injection of silica and trace element enriched melt comes into the mush and mixing with the interstitial melt that lead olivine to resorb. Lighter melt expel at the top of the melt lense and started nucleating clinopyroxene and orthopyroxene. Olivine resorption buffered Mg# so that the last crystal here clinopyroxene, but mostly orthopyroxene are highly enriched in the trace element with high Mg#.

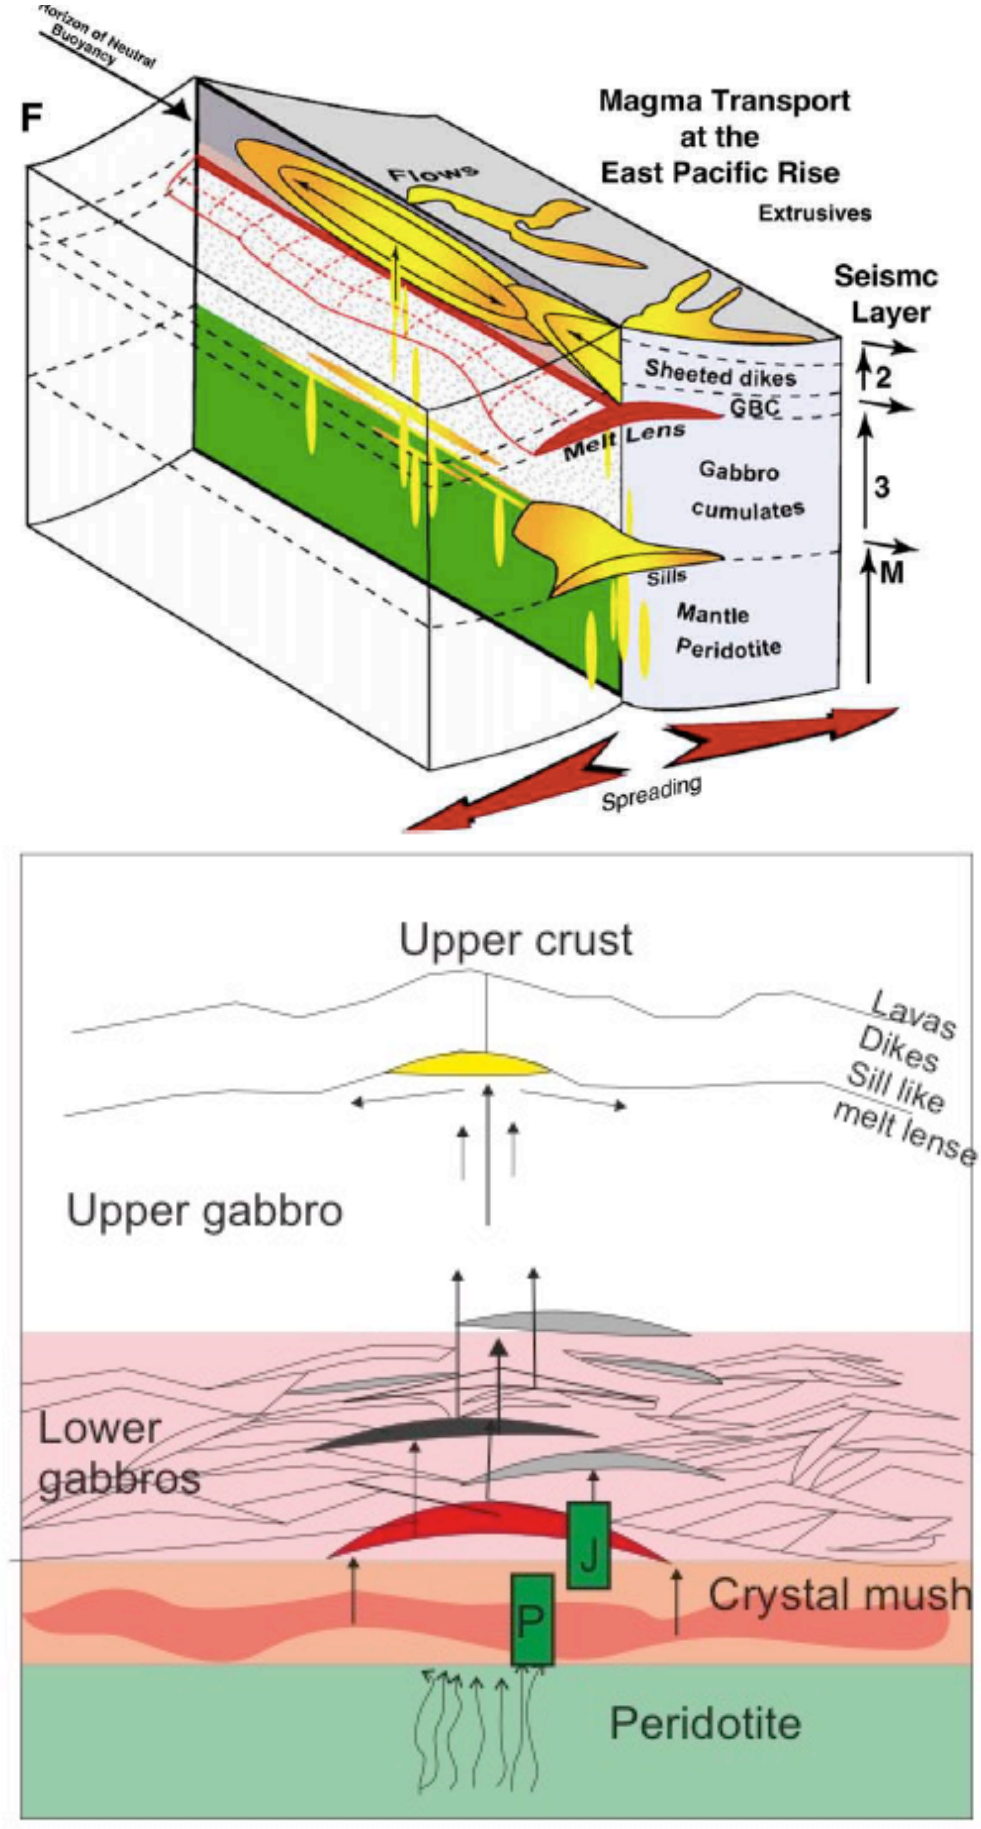

Figure 6.9: Diagram shows upper melt lense and lower melt lense presence beneath the EPR. Therefore the crystalline mush of layer 3 gabbros, act as a filter to explede the enriched magma from lower level to upper crustal level. Figure taken from Natland and Dick, 2009.

Chapter 7

7. Conclusion

Most studies about EPR indicated a MORB source for all basalts and a similar MORB source was also documented for Hess Deep upper gabbros (ODP Leg 147 report).

Our study showed that gabbros from Hole J are compatible with this model. However, although it is located only 110 m away from Hole J, Hole P gabbros show radically different chemical signature.

Two major events were involved in gabbro formation in Hess deep:

1) Crystallization of a MORB melt in a mush leading to formation of Hole J gabbros and upper gabbro;

2) Contamination from a Ti, Zr, REE, Si rich source, leading to the local crystallization of highly Ti, Al, Cr-enriched Opx and Cpx in Hole P.

The crystallization process implied melt buffered Mg#, by olivine resorption from Ol-rich troctolites formed in a deep picritic magma chamber. Troctolite present just below the Opx bearing gabbro have the same trace element characteristic as EPR lower crustal gabbro and EPR basaltic glass.

The best candidate for the enriched melt source is eclogitic layers in the mantle as suggested by the enrichment in Si together with incompatible elements. However, contamination by some melt similar to those emitted at the Galapagos hot spot cannot be totally ruled out on our chemical study basis.

This Si and incompatible elements enrichment was not found in the EPR basalts, suggesting that some melt may not be extracted from the magma chamber and completely crystallize in situ. We showed that the gabbroic mush may act as a chemical filter between

the mantle and basalts and only a certain type of magma will go through this filter to be emitted at the surface. This filter results in the blockage of some magma fractions in the deeper crustal levels and, in this case, prevents the contaminating primitive melts to be expelled out to the basaltic layer.

In this study case, non-extraction of light silica rich melts can be partly explained by a higher viscosity that prevent any trapped melt to escape from a crystal-rich mush. The amount of poikilitic crystals in studied samples suggest a maximum porosity of 25%. But as Cpx started to crystallize from a MORB mush before contamination, the porosity was probably lower at the mixing point so that the mush may have reach the permeability allowing to less viscous MORB melt to be expelled but not the viscous Si-rich melt in equilibrium with Opx. For the Opx richest gabbros, the relatively low amount of poikilitic Opx suggest a porosity level of 5 to 6% on average and lower than 15% in every cases.

Acknowledgments

First I would like to thank each and every one who has constantly supported me during this tenure. Without you, my thesis would never be completed. I had tried to acknowledge you all, if I had missed some one, I owe you an apology.

I am particularly indebted to my supervisor, Dr. Marie Python, for guiding me in every possible academic and non-academic aspect. Undoubtedly, you played the most crucial role to make this project possible. I do not have enough vocabulary to express my gratitude for the way you guided and supported me and allowed me to pursue research topics independently.

I am grateful to Prof. Toru Takeshita in Hokkaido University for his continuous encouragement and constructive criticism. I would also like to express my sincere thanks to Dr. Maeda Jin-ichiro, Dr. Makoto Kawamura, Dr. Jun Kameda in Hokkaido University, for pointing out the problem of my work, and gave me suitable suggestions in 6G seminars.

I appreciate the kind of support I had received from Prof. Marguerite Godard in University of Montpellier during my one-month stay there to use LA-ICPMS facility. The discussions with her were very effective and helped me build the final models of my thesis.

I would particularly like to thank my Masters' supervisor Dr Biswajit Ghosh for believing in my potential and recommending me for this PhD curriculum. I would also like to take the opportunity to thank Dr. Tapas Bhattyacharya (my M.Sc instructor) and Dr. Pinaki Bandopadhaya for their constant support and encouragements.

Special thank goes to Dr. Norikatsu Akizawa of Kyoto University for helpful discussion.

How I can acknowledge the members of Laboratory Hokkaido University! Especially Mr. Kohei Yamashita, Dr. Ayumi Okamoto, Mr. Keisuke Ishige (a recent doctor)! Without you guys I could not survive. You are the real reason that made me feel the lab, Hokkaido and Japan just like.my home. I would also like to thank every other members of Geotectonic group as well as Natural history science faculty for making my research life so smooth.

I also like to thank our educational affair section members, specifically Toko Kaneta san, Hiroko Hori san and Mari Igarashi san, without your help and support either in academic or nonacademic matter it would be almost impossible for me to sustain in new environment.

I cannot say thanks my fellow PhD colleague, my big brother Mr. Shivaji Saha, because it would be a humiliation. You had been a constant source of my smile, the every moments I spend with you are the cherished one.

I appreciate spending great time with Jagriti Mishra, Chetna Sharma, Rahul Jog, Sristi Dasgupta, Santoshi Saha, who are now just like a part of my family. The way supported me when I was homesick; you took care of mine when I was ill, made me realize that you are my true friend.

Much loves and many thanks to Mr. Debaditya Bandyopadhyay for supporting me in every possible means and encouraging me, especially during the hard time. Your sincere limitless support and understanding cannot be thanked enough.

Sincere gratitude, love, and respect for my parents, my sister, brother-in-law, my special Uncle and Aunty (Kaku and Kakima) and lots of love to my little angel - niece for supporting and help during all the years. I really appreciate that they having faith on me and always beside me. Without their support I would not have been able to finish this project.
