243 **ABSTRACT**
244
245
246
247

248 **BACKGROUND:** Underlying mechanisms behind the hypothesized relationship between
249 periodontal disease (PD) and coronary heart disease (CHD) have been insufficiently
250 explored. We evaluated associations between self-reported tooth loss, a marker of PD, and
251 prognostic biomarkers in 15,456 (97%) patients with stable CHD in the global STABILITY
252 trial.
253
254
255
256
257

258 **METHODS AND RESULTS:** Baseline blood samples were obtained and patients reported
259 their number of teeth according to the following tooth loss levels: “26–32 (All)” [lowest
260 level], “20–25”, “15–19”, “1–14”, and “No Teeth” [highest level]. Linear and Cox regression
261 models assessed associations between tooth loss levels, biomarker levels and the relationship
262 between tooth loss levels and outcomes, respectively.
263
264
265
266
267
268

269 After multivariable adjustment, the relative biomarker increase between the
270 highest and the lowest tooth loss level was: high-sensitivity C-reactive protein 1.21 (95%
271 confidence interval, 1.14-1.29), interleukin 6 1.14 (1.10-1.18), lipoprotein-associated
272 phospholipase A₂ activity 1.05 (1.03-1.06), growth differentiation factor 15 1.11 (1.08-1.14),
273 and N-terminal pro-B-type natriuretic peptide (NT-proBNP) 1.18 (1.11-1.25). No association
274 was detected for high-sensitivity troponin T 1.02 (0.98-1.05). Some attenuation of the
275 relationship between tooth loss and outcomes resulted from the addition of biomarkers to the
276 multivariable analysis, of which NT-proBNP had the biggest impact.
277
278
279
280
281
282
283
284
285

286 **CONCLUSIONS:** A graded and independent association between tooth loss and several
287 prognostic biomarkers was observed, suggesting that tooth loss and its underlying
288 mechanisms may be involved in multiple pathophysiological pathways also implicated in the
289 development and prognosis of CHD. The association between tooth loss and cardiovascular

363
364 **1. INTRODUCTION**
365

366 There is a growing body of evidence favouring an independent association between oral
367 health and coronary heart disease (CHD) [1–3]. We have recently reported an association
368 between tooth loss and cardiovascular (CV) outcomes, but not myocardial infarction (MI), in
369 a chronic CHD population [4]. In the literature, the hypothesized relationship between dental
370 disease and CV disease is often attributed to deleterious effects of periodontal disease (PD), a
371 highly prevalent chronic inflammatory condition ranging from early gingivitis to end-stage
372 tooth loss, on the atherosclerotic process but the specific mechanistic nature of such a
373 relationship remains elusive and debated [5].
374
375
376
377
378
379
380
381
382

383 Pathophysiological information on multiple aspects of etiology and progression
384 of CV disease is reflected by several biomarkers, many of which also have robust capabilities
385 of predicting prognosis [6–11]. Thus, associations between markers of PD, biomarkers and
386 CV outcomes could provide further insights about possible mechanisms connecting PD and
387 CV disease. However, such existing observations mainly stem from smaller populations and
388 are limited to selected inflammatory markers such as C-reactive protein and interleukin-6
389 [12,13], whereas reported associations with other important biomarkers are either scarce or
390 non-existent.
391
392
393
394
395
396
397
398

399 We evaluated associations between self-reported tooth loss, a marker of oral
400 disease and PD, and a wide range of prognostic biomarkers, including high-sensitivity
401 C-reactive protein (hs-CRP), interleukin-6 (IL-6), lipoprotein-associated phospholipase A₂
402 activity (Lp-PLA₂), growth differentiation factor 15 (GDF-15), high-sensitivity troponin T
403 (hs-Troponin T) and N-terminal pro-B-type natriuretic peptide (NT-proBNP) in a large global
404 CHD population. Further, we assessed the influence of these biomarkers on the ability of
405 self-reported tooth loss to predict CV outcomes.

2. METHODS

2.1. Study population

The STabilization of Atherosclerotic plaque By Initiation of darapLadIb TherapY (STABILITY) study evaluated the efficacy of darapladib, an oral inhibitor of lipoprotein-associated phospholipase A₂ activity (Lp-PLA₂) compared to placebo in addition to optimal medical treatment in 15,828 participants from 39 countries with stable CHD, defined as prior myocardial infarction (MI), prior coronary revascularization (percutaneous coronary intervention or coronary artery bypass grafting), or multivessel CHD without revascularization. At least one additional enrichment criterion was required: age ≥ 60 years; diabetes mellitus requiring pharmacotherapy; high-density lipoprotein cholesterol < 1.03 mmol/L; current or previous smoker defined as ≥ 5 cigarettes per day on average; moderate renal dysfunction (estimated glomerular filtration rate ≥ 30 and < 60 mL/min/1.73 m² or urine albumin:creatinine ratio ≥ 30 mg albumin/g creatinine); or polyvascular disease (co-existing disease in at least two arterial territories). Patients with an estimated glomerular filtration rate < 30 mL/min/1.73 m² were excluded [14]. After a median follow-up of 3.7 years, no difference in major adverse cardiovascular events (MACE, i.e. first occurrence of CV death, myocardial infarction or stroke) was observed for patients randomized to darapladib compared to placebo [15]. The ethics committees of each participating country approved the study and all patients provided written informed consent prior to inclusion. The STABILITY trial was performed in accordance with the Declaration of Helsinki.

2.2. Data collection

At baseline, 15,456 (97%) patients reported their number of teeth according to the following categories: “26–32 (All teeth)”, “20–25”, “15–19”, “1–14”, and “No Teeth”. For the purposes

481
482
483 of this report, these categories are termed tooth loss levels with 26-32 teeth corresponding to
484
485 the lowest level and no teeth, the highest level.
486

487
488 Blood samples for routine laboratory tests and storage for later analyses were
489
490 obtained in all 15,456 patients at baseline and prognostic biomarker analyses were performed
491
492 in the majority of patients. Plasma aliquots were stored at -70°C until biochemical analysis.
493
494 All routine biochemical and hs-CRP analyses were performed at a central laboratory with
495
496 standardized methods (Quest Diagnostics Clinical Laboratories, Inc., Valencia, California,
497
498 USA). Plasma concentrations of hs-CRP were analyzed using a particle-enhanced
499
500 immunonephelometry assay, *CardioPhase*® hsCRP, Siemens Healthcare. Plasma
501
502 concentrations of high-sensitivity IL-6 were analyzed using an ELISA technique, R&D
503
504 Systems Inc., Minneapolis, MN, U.S.A. Lp-PLA₂ activity was measured in an automated
505
506 enzyme assay system (PLAC® Test for Lp-PLA₂ Activity, diaDexus, San Francisco, CA,
507
508 USA). The other biomarker assays were performed at the UCR Laboratory at Uppsala
509
510 University, Uppsala, Sweden, GDF-15 was measured with the GDF-15 precommercial assay
511
512 (Roche Diagnostics, Penzberg, Germany), composed of a monoclonal mouse antibody for
513
514 capture and a monoclonal mouse antibody fragment, [F(ab')₂], for detection in a sandwich
515
516 assay format. Detection was based on an electrochemiluminescence immunoassay using a
517
518 ruthenium (II) complex label. Levels of hs-Troponin T and NT-proBNP were also determined
519
520 by electrochemiluminescence (Roche Diagnostics, Penzberg, Germany). The Cobas
521
522 Analytics e601 was used for the Roche immunoassays.
523
524
525
526
527

528 **2.3. Statistical analysis**

529
530 Baseline variables are presented as mean, standard deviation and percentages. Baseline
531
532 biomarker levels are presented as median and interquartile range. Baseline biomarker levels
533
534 by tooth loss level were compared using the Kruskal-Wallis tests.
535
536
537

541
542
543 To determine associations between tooth loss levels and biomarker levels, each
544 biomarker was modelled as a function of tooth loss level (five levels). All biomarkers were
545 analyzed on a log-transformed scale using linear models. Geometric mean ratios are presented
546 with 95% confidence intervals (CI) with the lowest tooth loss level (26-32 teeth) as
547 reference, and according to three adjustment models. Model 1 adjusted for randomized
548 treatment. Model 2 adjusted for Model 1 and prior MI, prior coronary revascularization,
549 multi-vessel CHD, age, sex, geographic region, diabetes mellitus, hypertension, renal
550 dysfunction, body mass index, smoking (current, former or never), systolic blood pressure
551 and polyvascular disease. Model 3 adjusted for Model 2 and estimated glomerular filtration
552 rate (according to The Chronic Kidney Disease Epidemiology Collaboration equation,
553 replacing significant renal dysfunction) [16], hemoglobin, white blood cells, low-density
554 lipoprotein cholesterol, high-density lipoprotein cholesterol and triglycerides. Cox
555 proportional hazards models were used to calculate hazard ratios for MACE, CV death and
556 stroke in relation to tooth loss levels, adjusting for biomarkers in addition to a previously
557 reported multivariable model [4], co-variables of which are also listed in Table 3. In these
558 models, all biomarkers except Lp-PLA₂ activity were added after log-transformation. The
559 association between tooth loss and MI has previously been found to be absent in this cohort
560 and was not re-analysed in the present analysis.

3. RESULTS

3.1. Baseline characteristics and associations with biomarkers

Patients with higher tooth loss levels were older, were more likely to be female and had a greater CV risk factor burden, particularly a higher prevalence of smoking, diabetes mellitus, hypertension and impaired renal function compared to those with lower tooth loss levels (Table 1). Patients with more tooth loss had progressively higher baseline levels of hs-CRP, IL-6, Lp-PLA₂ activity, GDF-15, hs-Troponin T and NT-proBNP (Table 2). As demonstrated in Figure 1, higher tooth loss levels were associated with progressively greater relative increases for all prognostic biomarkers in relation to the lowest tooth loss level in Model 1. After multivariable adjustment the association remained statistically significant for all biomarkers, except for hs-Troponin T.

3.2. Tooth loss and outcomes

Table 3 demonstrates the association between a one-level increase in tooth loss and the risk of MACE, CV death and stroke according to the three adjustment models after a median follow-up of 3.7 years. The data up until Model 2 have been previously presented [4] showing a relative risk increase of 1.06, 1.17 and 1.14 for MACE, CV death and for stroke, respectively, for every one-level increase in tooth loss. The subsequent addition of biomarkers, individually and in groups, only attenuated the results slightly. Nevertheless, the addition of IL-6 and NT-proBNP rendered the association with MACE non-significant. Despite adjustment for all biomarkers and other co-variables, the association between tooth loss and CV death and stroke persisted.

4. DISCUSSION

We found that tooth loss, a marker of PD, was associated with higher levels of several CV biomarkers indicating a potential relationship between tooth loss and several pathophysiological mechanisms relevant to CV morbidity and mortality, including inflammation, cellular integrity and myocardial dysfunction [6,7,9,17]. Adjustment for the biomarkers somewhat attenuated the risk of adverse outcome, signalling a potential relevance of the pathways they represent in the relationship between tooth loss and increased CV risk. However, much of the risk increase remained, suggesting that other and presently unknown mechanisms could be of importance, although confounding cannot be excluded.

The host-mediated inflammatory response to PD constitutes the most commonly proposed mechanism linking oral disease with CHD and CV disease [18], mainly based on evidence from smaller studies of moderate associations between various measures of PD and elevation of inflammatory markers [12,13,19] and studies showing reductions of CRP and IL-6 levels after PD treatment [20]. This is the first study to corroborate these findings on a large scale in a global CHD population, including both upstream and downstream inflammatory markers, with comprehensive adjustment and with tooth loss as the exposure measure. Moreover, the association with Lp-PLA₂ activity, previously only assessed in small patient populations [21], could represent an additional alternative and independent inflammatory link [22]. However, our findings could represent a challenge to the inflammation hypothesis as the highest levels of inflammatory markers were observed among the edentulous, who are most likely rid of oral substrates for inflammation. This could indicate that intrinsic factors and not PD explain the inflammatory activity, for instance pro-inflammatory genetic traits and epigenetic modifications common to both advanced PD and CHD [23,24]. However, it is also conceivable that many years' exposure to chronic oral inflammation could instigate a secondary response in other locations, e.g.

721
722
723 atherosclerosis in blood vessels, which in turn could promote or maintain an elevated
724
725 systemic inflammatory response.
726

727 Associations with biomarkers that reflect other than inflammatory processes
728
729 could suggest a relevance of alternative pathophysiological pathways in the tooth loss-CV
730
731 disease relationship. The association with GDF-15 for instance, has not been previously
732
733 described and could partly reflect a relationship between tooth loss and inflammation but also
734
735 other harmful mechanisms [17] of relevance to several cardiac afflictions, including MI and
736
737 heart failure, to which GDF-15 has been previously associated [25,26]. An independent
738
739 association with cardiac biomarkers could support a more specific link between tooth loss, its
740
741 antecedents, and cardiac pathology. This was previously investigated in a small study where
742
743 44 patients with clinical evidence of PD had higher levels of troponin and NT-proBNP
744
745 compared to controls, however these associations were unadjusted [27]. The association with
746
747 NT-proBNP in our study suggests a relationship between tooth loss and baseline cardiac
748
749 dysfunction that persisted after adjustment for traditional important heart failure determinants,
750
751 including prior MI, hypertension and diabetes. Cross-reactivity between periodontal
752
753 and myocardial antigens and chronic toll-like receptor activation have been
754
755 suggested as potential mechanisms linking chronic infection, e.g. PD, to heart failure [28].
756
757 Furthermore, a recent study demonstrated a greater burden of PD among patients with
758
759 advanced HF awaiting heart transplantation compared to controls without HF. However, the
760
761 observed differences were attenuated to non-significance after adjustment for markers of oral
762
763 hygiene, race and 25- hydroxyvitamin D levels [29]. Overall, data on the role of PD in the
764
765 pathophysiology of heart failure is largely lacking but the results from our present study and
766
767 other studies are interesting from a hypothesis generating perspective and should be explored
768
769 further.
770
771
772

773
774 Conversely to the association with NT-proBNP, tooth loss did not appear to be related to
775
776
777

781 mechanisms generating elevated levels of troponin [30], which is an interesting finding
782
783 concurrent with the absent association between tooth loss and MI in this population [4].
784
785
786

787 In contrast to the absent MI association we recently reported a significant
788 association between tooth loss and MACE, CV death and stroke. Although the demonstrated
789 risk increases were relatively modest between adjacent tooth loss levels, they were more
790 substantial and likely to be clinically relevant when comparing patients with severe or
791 complete tooth loss to those with little or no tooth loss, particularly for CV death and stroke
792 [4]. In the present analysis, we added biomarkers to the previous outcomes model to assess
793 their influence on the demonstrated relationship between tooth loss and prognosis. Of the
794 inflammatory markers, IL-6, an upstream marker, attenuated the results the most and
795 eliminated the MACE association, supporting the hypothesis of inflammation as a mediator in
796 the PD-CV outcomes relationship further. However, for most of the biomarkers, resulting
797 attenuations were relatively small. The addition of NT-proBNP had the most pronounced
798 attenuating effect on the risk of adverse outcome, indicating a prognostic relevance of the
799 observed relationship between tooth loss and baseline myocardial dysfunction. The fact that a
800 significant portion of the increased risk for CV death and stroke persisted despite full
801 adjustment implies that alternate and presently unidentified pathways could be involved. The
802 observation of stronger associations for CV death and stroke compared to MI further suggests
803 that such pathways may be other than atherosclerotic and inflammatory, which is also
804 consistent with the associations to biomarkers reflecting other than primarily inflammatory
805 mechanisms, including GDF-15 and NT-proBNP. While the additional adjustment for
806 biomarkers could lead to underestimation of the true influence of tooth loss on prognosis by
807 removing effects of potential intermediate pathways, it also likely lessens the impact of
808 residual confounding, which is undoubtedly a considerable obstacle when assessing causality.
809 Nevertheless, as our findings are purely observational, causality cannot be inferred and they

832
833
834
835
836
837

841
842
843 may in fact be a product of long-term influence by causal factors common to both tooth loss
844
845 and CV disease.
846

847 From a prediction perspective and irrespective of causality, the observations
848
849 show promise for the potential use of self-reported tooth loss as a prognostication tool in
850
851 chronic CHD. Given its ability to predict several important outcomes combined with other
852
853 qualities, including its straightforward obtainability and affordability, the clinical predictive
854
855 utility of self-reported tooth loss should be explored further.
856
857

858 859 **4.1. Study limitations**

860
861 Self-reported tooth loss was the sole marker of PD in this analysis and the use of additional
862
863 exposure measures, e.g. clinical, could have provided better information regarding the
864
865 underlying etiology of tooth loss in the individual subjects. However, the literature generally
866
867 exhibits a lack of consistency in the use of PD definitions [5] and PD has been shown to be
868
869 the most common cause of tooth loss in older populations [31], although other causes, most
870
871 importantly caries, must be acknowledged. Moreover, self-reported tooth loss has been
872
873 validated against number of teeth on clinical examination with concurring results [32]. The
874
875 cross-sectional multivariable analysis of the association between tooth loss and biomarker
876
877 levels did not include markers of socioeconomic status, which could be important
878
879 confounders. Finally, the analysis does not specifically disclose the nature of the observed
880
881 associations, i.e. whether tooth loss and its underlying mechanisms increases CV risk or vice
882
883 versa, or if the two conditions are driven by a common etiology.
884
885
886
887
888
889

890 **4.2. Conclusion**

891
892 Self-reported tooth loss was associated with progressively higher levels of several prognostic
893
894 CV biomarkers suggesting possible involvement of tooth loss-generating mechanisms,
895
896
897
898
899
900

901
902
903 including PD, in multiple pathophysiological pathways relevant to both CHD development
904
905 and prognosis. Adjustment for a wide range of CV risk factors, socioeconomic status and
906
907 biomarkers eliminated the association with MACE but the association with CV death and
908
909 stroke persisted.

Author Agreement Form – International Journal of Cardiology

Manuscript Title: Associations between Tooth Loss and Prognostic Biomarkers and the Risk for Cardiovascular Events in Patients with Stable Coronary Heart Disease

List of all Authors: Ola Vedin, MD, PhD; Emil Hagström, MD, PhD; Ollie Östlund, PhD; Alvaro Avezum, MD, PhD; Andrzej Budaj, MD, PhD; Marcus D. Flather, MBBS; Robert A. Harrington, MD; Wolfgang Koenig, MD; Joseph Soffer, MD; Agneta Siegbahn, MD, PhD; Philippe Gabriel Steg, MD; Ralph A. H. Stewart, MD; Lars Wallentin, MD, PhD; Harvey D. White, MB, ChB, DSc; Claes Held, MD, PhD.

Corresponding Author: Ola Vedin

This statement is to certify that all authors have seen and approved the manuscript being submitted, have contributed significantly to the work, attest to the validity and legitimacy of the data and its interpretation, and agree to its submission to the *International Journal of Cardiology*.

We attest that the article is the Authors' original work, has not received prior publication and is not under consideration for publication elsewhere. We adhere to the statement of ethical publishing as appears in the International of Cardiology (citable as: Shewan LG, Rosano GMC, Henein MY, Coats AJS. A statement on ethical standards in publishing scientific articles in the International Journal of Cardiology family of journals. *Int. J. Cardiol.* 170 (2014) 253-254 DOI:10.1016/j.ijcard.2013.11).

On behalf of all Co-Authors, the corresponding Author shall bear full responsibility for the submission. Any changes to the list of authors, including changes in order, additions or removals will require the submission of a new author agreement form approved and signed by all the original and added submitting authors.

All authors are requested to disclose any actual or potential conflict of interest including any financial, personal or other relationships with other people or organizations within three years of beginning the submitted work that could inappropriately influence, or be perceived to influence, their work. If there are no conflicts of interest, the COI should read: "The authors report no relationships that could be construed as a conflict of interest".
