4
5

6 27
7

8 28 **Aim**
9

10
11 29 Recent epidemiological studies indicate increases in hospital food allergy-related
12
13 30 anaphylaxis admission rates in Australian and New Zealand. The aim of the study
14
15 31 was to examine whether non-IgE mediated food allergy might have increased in
16
17 32 parallel.
18
19

20 33 **Methods**
21

22
23 34 We analysed childhood hospital admissions rates by ICD 10 codes for allergic
24
25 35 gastroenteritis (AG) and infective gastroenteritis in Australia and New Zealand
26
27 36 between June 1998 and July 2014.
28
29

30 37 **Results**
31

32
33 38 In Australia most AG-related admissions (73%) occurred in those aged <1 year
34
35 39 and increased by 7.3%/year (95%CI 5.5-9.3, P<0.0001) from 6.8 to 26.5/10⁵
36
37 40 population. Similar trends were observed for New Zealand; 81% of admissions
38
39 41 occurred in those aged <1 year and increased by 9.4%/year (95%CI 5.5-9.3,
40
41 42 P<0.0001) from 7.2 to 30.7/10⁵ population. By contrast there were no significant
42
43 43 changes in AG-related admission rates in the older patients and infective
44
45 44 gastroenteritis admissions fell in both countries in those aged < 1 year; Australia
46
47 45 by 4.4%/year (95%CI 4.3-4.6, P<0.0001) and in New Zealand by 5.8%/year
48
49 46 (95%CI 5.4-6.2, P<0.0001).

56
57
58
59
60

1
2
3 **48 Conclusions**
4

5 49 We observed a four-fold increase in AG-related admission rates in two countries
6
7 50 with known high rates of IgE-mediated food allergy/anaphylaxis. If confirmed by
8
9 51 other studies, it will be of interest to determine if factors thought to contribute to
10
11 52 the increase in IgE-mediated FA⁸ might also play a role in non-IgE mediated
12
13
14 53 gastroenterological FA syndromes.
15
16

17 54

18
19 55

20
21 **56 What is known on this topic**
22

- 23
24 57 • IgE-mediated childhood food allergy has increased over the last 20 years in
25
26 58 Australia and New Zealand.
27
28 59 • It is unknown whether non-IgE-mediated food allergy has increased as well.
29

30 60

31
32
33 **61 What this paper adds**
34

- 35 62 • Hospital admissions for allergic gastroenteritis (but not infective
36
37 63 gastroenteritis) increased four-fold between 1998 and 2014.
38
39 64 • If this represents a true increase (and not greater recognition), it remains
40
41 65 uncertain whether the same risk factors for IgE-mediated food allergy are
42
43 66 relevant for non-IgE-mediated food allergy.

67 Introduction

68 Epidemiological data (e.g. hospitalization rates) indicate that IgE-mediated food
69 allergy (FA) and anaphylaxis has increased over the past 2 decades^{1,2}. With the
70 possible exception of eosinophilic esophagitis³ and coeliac disease, it is unclear
71 whether other non-IgE mediated FA may have increased as well. “Allergic
72 gastroenteritis” (AG) as classified under the International Statistical
73 Classification of Diseases (ICD-10) encompasses a number of non-IgE mediated
74 allergic conditions, including food protein-induced enterocolitis syndrome
75 (FPIES), eosinophilic enteritis and colitis, food protein-induced enteropathy,
76 “other allergic dietetic gastroenteritis and colitis”, food hypersensitivity enteritis
77 and colitis (but specifically not eosinophilic oesophagitis or coeliac disease). We
78 sought to determine whether AG-related paediatric hospital admission rates
79 have increased in parallel with increases in food-related IgE-mediated
80 anaphylaxis in Australia and New Zealand

82 Methodology

83 We obtained ICD-10 classified hospital admissions data, as collected by the
84 Australian Institute of Health and Welfare and the New Zealand Ministry of
85 Health. Hospital admissions between July 1998 (Australia) or July 2000 (New
86 Zealand) to June 2014 attributed to AG (K52.2) were examined. Infective
87 gastroenteritis admissions (A0 to A9) and all cause admissions (available for
88 Australia only) were examined as comparators to control for any trend for
89 overall increased hospitalisation for gastrointestinal disorders that may have
90 confounded analysis. Age ranges of < 1 year, 1-4 years and 5-14 years were
91 selected to facilitate comparison with other admissions-related studies². More

1
2
3 92 detailed codes for FPIES (K52.21), food protein-induced enteropathy (K52.22) or
4
5 93 the term “other allergic dietetic gastroenteritis and colitis” (K52.29) were
6
7
8 94 unavailable from the institutions providing data (AIHW, NZ MoH). Data are
9
10 95 expressed as rates/10⁵ population using concurrent national population data².
11
12 96 Time trends were analyzed using Poisson regression with year as a continuous
13
14 97 predictor and total population as exposure variable. Analysis was performed
15
16 98 using SAS 9.3 statistical software. The Human Research and Ethics committee of
17
18 99 Calvary Bruce/Calvary John James Private Hospitals, Canberra, Australia
19
20
21 100 approved the study.
22
23
24
25
26
27

28 **Results**

29
30
31 103 Hospital admissions for AG increased over the study period in Australia and New
32
33 104 Zealand. In Australia most AG-related admissions (73%) occurred in those aged
34
35 105 <1 year with slight male predominance (58%) and increased by 7.3%/year
36
37 106 (95%CI 5.5-9.3, P<0.0001) from 6.8 to 26.5/10⁵ population (**Table 1, Figure 1A**).
38
39

40
41 107 Similar trends were observed in New Zealand AG-related admissions; 81%
42
43 108 occurred in those aged <1 year with slight male predominance (59%) and
44
45 109 increased by 9.4%/year (95%CI 5.5-9.3, P<0.0001) from 7.2 to 30.7/10⁵
46
47 110 population (**Figure 1B**). By contrast there were no significant changes in AG-
48
49 111 related admission rates in the two older age groups in either country (**Table 1**).
50
51

52
53 112 When infective gastroenteritis admissions were examined as comparators, these
54
55 113 decreased in Australia by 4.4%/year (95%CI 4.3-4.6, P<0.0001) and in New
56
57 114 Zealand by 5.8%/year (95%CI 5.4-6.2, P<0.0001) in those aged <1 year. In
58
59
60

1
2
3 115 Australia there was a minor decrease in all-cause admissions of 0.1%/year
4
5 116 (95%CI 0-0.1, P=0.0001).
6
7

8 117 **Discussion**

9
10 118 We report a 4-fold increase in AG-related hospital admission rates for AG in
11
12 119 Australia and New Zealand in infants aged <1 year between 1998/99 and
13
14 120 2013/14. These trends ([with slight male predominance and very similar rates](#)
15
16 121 [between the two countries](#)) could not be explained by increases in overall
17
18 122 hospitalization rates, or consistent changes in admission rates for potentially
19
20 123 mimicking conditions such as infective gastroenteritis ~~admissions~~[admissions](#).
21
22 124 [which decreased over the period of observation \(likely related to update of](#)
23
24 125 [rotavirus immunization\)](#). AG-related admissions were almost absent in older
25
26 126 Australasian age groups.
27
28
29
30

31 127
32
33 128 Many epidemiological studies rely upon ICD coding to track changes in rates of
34
35 129 disease, or changes of distribution and burden of diseases within populations. In
36
37 130 addition to the many potential caveats involved in using coding data of this
38
39 131 nature³ there are as yet unresolved questions about exactly what the K52.2 ICD
40
41 132 code represents in practice and how coders are interpreting admissions data to
42
43 133 make this decision about the admission. [Accurate coding also relies upon the](#)
44
45 134 [diagnostic expertise of the health professionals making the diagnosis during the](#)
46
47 135 [hospital admission.](#) The code is designed to identify food protein-induced
48
49 136 enterocolitis syndrome (FPIES), eosinophilic enteritis and colitis, food protein-
50
51 137 induced enteropathy, food hypersensitivity enteritis and colitis but specifically
52
53 138 not eosinophilic oesophagitis or coeliac disease. While it would have been
54
55
56
57
58
59
60

1
2
3 139 informative to examine more detailed disease specific codes, such data is not
4
5 140 available for Australia or New Zealand at this time.
6

7
8 141

9
10 142 Overall, our data suggest a possible increase in non-IgE-mediated FA related
11
12 143 disorders such as has been already reported with eosinophilic esophagitis
13
14 144 diagnostic rates³ and is consistent with reports of increasing FPIES presentations
15
16 145 to large allergy referral centres in Australia⁴ and Italy⁵ although not the USA⁶.

17
18 146 While it is interesting to speculate that the increases in infant AG admissions
19
20 147 might represent FPIES, with increases in infants presenting with the profuse
21
22 148 vomiting, pallor and hypotension characteristic of FPIES requiring admission
23
24 149 (rather than emergency department assessment and discharge), such
25
26 150 conclusions are precluded by the limitations of coding data and thus inability to
27
28 151 differentiate from other related conditions (eg. food induced enteropathy with
29
30 152 failure to thrive) or mimicking conditions (infective gastroenteritis). The
31
32 153 observation that rates of admission for AG in both countries for the <1 year age
33
34 154 group were very similar is supportive of the possibility that the majority of these
35
36 155 cases represent FPIES. If the increase in AG is confirmed by other studies, and
37
38 156 not an solely an artefact of improved recognition of disorders such as FPIES⁷ and
39
40 157 coding, it will be of interest to determine if factors thought to contribute to the
41
42 158 increase in IgE-mediated FA⁸ might also play a role in non-IgE mediated
43
44 159 gastroenterological FA syndromes.
