24

25 **Abstract**

26 The germline stem cells (GSCs) are critical for gametogenesis throughout the adult life. Stem  
27 cell identity is maintained by local signals from a specialized microenvironment called the  
28 niche. However, it is unclear how systemic signals regulate stem cell activity in response to  
29 environmental cues. In our previous article, we reported that mating stimulates GSC  
30 proliferation in female *Drosophila*. The mating-induced GSC proliferation is mediated by  
31 ovarian ecdysteroids, whose biosynthesis is positively controlled by Sex peptide signaling.  
32 Here, we characterized the post-eclosion and post-mating expression pattern of the genes  
33 encoding the ecdysteroidogenic enzymes in the ovary. We further investigated the  
34 biosynthetic functions of the ovarian ecdysteroid in GSC maintenance in the mated females.  
35 We also briefly discuss the regulation of the ecdysteroidogenic enzyme-encoding genes and  
36 the subsequent ecdysteroid biosynthesis in the ovary of the adult *Drosophila*.

37

## 38 Introduction

39           In many animals, sperm and egg production requires a robust stem cell system that  
40 balances self-renewal with differentiation.<sup>1</sup> Germline stem cells (GSCs) produce progeny germ  
41 cells that differentiate into gametes and replicate themselves to maintain the generative cell  
42 population. The balance between self-renewal and differentiation of GSCs is important because  
43 perturbation of this balance causes germ cell depletion, infertility or tumorigenesis.<sup>1,2</sup> GSCs are  
44 maintained by a specialized microenvironment called the niche.<sup>3</sup> The niche provides local  
45 signals to maintain stem cell identity.<sup>4</sup> Furthermore, GSC number is also controlled by systemic  
46 signals, including the insect steroid hormone ecdysteroids,<sup>5-11</sup> which are also known as  
47 “molting hormones”. In the larval stage, ecdysteroids are biosynthesized from dietary  
48 cholesterol through several catalyzed steps in the specialized endocrine organ called the  
49 prothoracic gland. Recently, molecular studies have identified several ecdysteroidogenic  
50 enzymes such as Noppera-bo,<sup>12-14</sup> Neverland,<sup>15-17</sup> Non-molting glossy/Shroud,<sup>18</sup>  
51 CYP307A1/Spook,<sup>19,20</sup> CYP307A2/Spookier,<sup>19</sup> CYP306A1/Phantom,<sup>21,22</sup>  
52 CYP302A1/Disembodied,<sup>23-25</sup> CYP315A1/Shadow,<sup>24</sup> and CYP314A1/Shade<sup>26</sup> (Fig. 1A).  
53 Molecular genetics has revealed that ecdysteroid signaling is indeed active in adult insects, and  
54 is involved in controlling multiple steps during adult oogenesis, including egg chamber  
55 development and vitellogenesis,<sup>27,28</sup> follicle growth and survival,<sup>9,29</sup> and stem cell niche  
56 formation.<sup>9</sup> In addition, certain genes encoding the ecdysteroidogenic enzymes are required for  
57 egg development after stage 8,<sup>19,26</sup> egg production,<sup>30</sup> and border cell migration.<sup>31</sup>

58           It is well-documented that for the regulation of molting and metamorphosis, the  
59 biosynthesis and signaling of ecdysteroids are coordinately modulated in response to various  
60 environmental cues such as nutrition, photoperiod, and temperature.<sup>32,33</sup> Therefore, it is  
61 possible that the environmental cues are also reflected in egg production processes such as in  
62 the control of GSC number. However, the mechanism by which ecdysteroids regulate GSCs in

63 response to environmental cues is unclear.

64           One of the major environmental cues that affect egg production is the mating  
65 stimulus. In the *Drosophila* female, mating induces dramatic changes in reproductive behavior  
66 such as increased egg laying and decreased mating behavior.<sup>34,35</sup> The post-mating response is  
67 triggered by the male's Sex peptide (SP), which is present in the seminal fluid and transferred to  
68 the female during copulation.<sup>36-38</sup> Because mating functions as a switch for reproductive  
69 activation, the demand for gametes increases during mating to generate more offspring.  
70 Therefore, it is possible that mating modulates GSC activity to activate gametogenesis and  
71 increase the supply of eggs. This is indeed the case, as our previous study has demonstrated that  
72 GSC number increases in response to mating.<sup>30</sup> Moreover, we also found that the  
73 mating-induced GSC increase is mediated by ovarian ecdysteroids.<sup>30</sup> In contrast, the underlying  
74 mechanisms that control ovarian ecdysteroid biosynthesis in virgin and mated females are still  
75 unknown.

76           In this Extra View, we extend our previous findings by characterizing the expression  
77 pattern of the ecdysteroidogenic enzyme-encoding genes in the ovary in the post-eclosed and  
78 post-mated periods. In addition, we show that ovarian ecdysteroid biosynthesis has a long-term  
79 effect on GSC maintenance in the mated female flies.

80

81 Results and Discussion

## 82 **Expression of ecdysteroidogenic enzyme-encoding genes in the ovary of virgin** 83 **females**

84 In our original paper, we have demonstrated that ovarian ecdysteroid biosynthesis is activated  
85 by mating stimuli, and the level of the ovarian ecdysteroid in the mated females is significantly  
86 higher than that in the virgin females.<sup>30</sup> In addition, our data suggest that this activation, at least  
87 in part, results from transcriptional up-regulation of ecdysteroidogenic enzyme-encoding

88 genes.<sup>30</sup> Moreover, several previous studies have reported that the ovarian ecdysteroid is  
89 detected in virgin females.<sup>39,40</sup> Especially, Tu et al. describe the changes in ecdysteroid level in  
90 the wild type ovary 0–48 hours after eclosion without mating. Interestingly, a peak in the levels  
91 of the ovarian ecdysteroid is observed in virgin female flies approximately 18 hours after  
92 eclosion, which may be required for initiating oogenesis.<sup>40</sup> This observation suggests that the  
93 expression of the genes encoding the ecdysteroidogenic enzymes fluctuate temporally even in  
94 virgin females. However, this scenario has not yet been tested.

95 We therefore investigated the transcription pattern of the ecdysteroidogenic  
96 enzyme-encoding genes, including *noppera-bo* (*nobo*), *neverland* (*nvd*), *shroud* (*sro*), *spook*  
97 (*spo*), *phantom* (*phm*), *disembodied* (*dib*), *shadow* (*sad*), and *shade* (*shd*) (Fig. 1A) in virgin  
98 females. The ovaries of the virgin females were dissected at 3-hour intervals within the first 6 to  
99 27 hours post-eclosion. We observed that the expression levels of certain genes, namely, *nobo*,  
100 *nvd*, *sro*, and *phm*, gradually decreased after eclosion, while there was no significant change in  
101 the temporal expression of *dib* and *sad* (Fig. 1B). However, we observed a significant increase  
102 in the *spo* and *shd* mRNA abundance at 15–21 hours post-eclosion (Fig. 1B). Taken together,  
103 most of the genes were highly expressed until 18 hours after eclosion. We speculate that the  
104 expression of the ecdysteroidogenic enzyme-encoding genes might be a preparation to achieve  
105 the highest level of ovarian ecdysteroids at 18 hours post-eclosion.<sup>40</sup> In contrast, most of the  
106 genes involved in biosynthesis showed lower expression levels 18–21 hours after eclosion and  
107 later, when the virgin females had lower ecdysteroid levels in the ovary.<sup>40</sup> These results suggest  
108 that the ecdysteroidogenic enzyme-encoding gene expression is regulated not only in the mated  
109 females but also in the virgin females, implying that unknown tropic stimuli, other than the  
110 mating stimuli, may be involved in controlling the ovarian ecdysteroid biosynthesis in the  
111 post-eclosion period. However, it should be noted that the physiological relevance of the  
112 temporal change in individual ecdysteroidogenic enzyme-coding genes is unclear so far.

113

114 **Sex peptide and its receptor up-regulate the expression of the**  
115 **ecdysteroidogenic enzyme-encoding genes differently.**

116 We have previously found that the mating-induced ecdysteroid biosynthesis is mediated by the  
117 male-derived SP and its receptor SPR, the components of a canonical neuronal pathway that  
118 induces a post-mating behavioral switch in females.<sup>30,37,41,42</sup> Moreover, we have described that  
119 flies with a loss of SPR function exhibit significant reduction in *nvd* and *phm* expression.<sup>30</sup> To  
120 further investigate how SP signaling affects the expression of the ecdysteroidogenic  
121 enzyme-encoding genes in the ovary, we examined their expression levels in wild-type female  
122 flies that were mated with the *SP* null mutant males (the ligand mutant).<sup>41</sup> We found that the  
123 female flies that mated with the control males showed increased expression of certain  
124 ecdysteroidogenic enzyme-encoding genes, including *sro*, *spo*, *phm*, *sad*, and *shd*, compared to  
125 those in the virgin female flies (Fig. 1C). However, mating with the *SP* null mutant males did  
126 not induce any increase in transcript levels of most of the genes except for *spo* (Fig. 1C). These  
127 results suggest that mating up-regulates the transcription of the ecdysteroidogenic  
128 enzyme-encoding genes in the ovary via SP from the male's seminal fluid. In addition, it is  
129 noteworthy that SP appears to influence the expression of more ecdysteroidogenic  
130 enzyme-encoding genes than SPR.<sup>30</sup> These results imply that SP might affect the expression of  
131 the ecdysteroidogenic enzyme-encoding genes in the ovary via both the SPR-dependent  
132 pathway and an unknown SPR-independent pathway.

133

134 **Ovarian ecdysteroid biosynthesis and GSC maintenance**

135 While our previous study has revealed an indispensable role of ecdysteroids in GSC  
136 proliferation within 24 hours after mating, other studies have demonstrated that the ovarian  
137 ecdysteroid signaling and its downstream cascade are essential for many aspects of

138 oogenesis,<sup>9,27-29,43</sup> particularly GSC maintenance,<sup>5-10</sup> over a week and more after mating.  
139 Therefore, we examined the effect of ecdysteroid biosynthesis on oogenesis, including stem  
140 cell regulation, after mating and over a longer period post-mating. We have previously reported  
141 that mating increases GSC number and this increase is maintained after 6 days from the first  
142 mating.<sup>30</sup> To confirm the role of the ovarian ecdysteroid in GSC maintenance for over a week,  
143 we dissected ovaries from 2-week-old females at 1 week after mating (Fig. 2A).

144 To generate the ovary in which ecdysteroid biosynthesis is impaired, we knocked down  
145 *nvd*, which encodes the ecdysteroidogenic enzyme responsible for catalyzing the first step of  
146 the ecdysteroid biosynthesis pathway,<sup>16,17</sup> by transgenic RNA interference (RNAi) with the  
147 *c587-GAL4* driver. While the *c587-GAL4* driver is known to be active in adult ovarian somatic  
148 cells, including escort cells and follicle cells, but not in nurse cells, we have previously found  
149 that the *c587-GAL4*-driven *nvd* RNAi (*c587>nvd* RNAi) efficiently leads to a significant  
150 reduction of NVD protein levels in both follicle and nurse cells for unknown reasons.<sup>30</sup> In  
151 addition, we have reported that *c587>nvd* RNAi leads to reduction in ovarian ecdysteroid  
152 levels compared to those in control animals.<sup>30</sup>

153 In the experimental flies that underwent the mating protocol shown in Fig. 2A, we  
154 found that the *c587>nvd* RNAi female flies had significantly less GSCs (1.90 GSCs on  
155 average) compared to that in the control female flies (2.13 GSCs on average) (Fig. 2D, left). To  
156 eliminate the possibility of developmental defects in oogenesis caused by this genotype  
157 (*c587-GAL4* is already active in somatic cells at the larval stage),<sup>44</sup> we confirmed that the  
158 number of GSCs in the female flies were not affected by the *c587>nvd* RNAi condition 1 day  
159 after eclosion compared to those in the control flies (Fig. 2D, right). Second, there were no  
160 differences in GSC number between the *c587>nvd* RNAi and control pre-mating flies, which  
161 were at 1 week after eclosion (Fig. 2D, right). These results suggested that *c587>nvd* RNAi  
162 does not affect GSC establishment during either pre-adult oogenesis or pre-mating ovarian

163 maturation. In other words, our data strongly support our hypothesis that ovarian ecdysteroid  
164 biosynthesis in the adult stage is required for GSC maintenance in the mated females. We also  
165 tested whether ecdysteroid biosynthesis affects the process of germ cell differentiation in the  
166 germarium. However, we did not observe any changes in the number of germ cells in the  
167 cystoblast, 2-cell cyst, 4-cell cyst, 8-cell cyst, and 16-cell cyst (Fig. 2B) in the *c587>nvd* RNAi  
168 female flies (Fig. 2E). In addition, the number of egg chambers in each stage (Fig. 2C) was not  
169 affected by the down-regulation of *nvd* in the ovary (Fig. 2F). Taken together, ovarian  
170 ecdysteroid biosynthesis controls the number of GSC, but not the number of differentiating  
171 germ cells and stage of the egg chamber.

172         We next examined whether the GSC maintenance phenotype in the *c587>nvd* RNAi is  
173 caused by a reduction in ovarian ecdysteroid levels. We measured the ovarian ecdysteroid  
174 levels in the *c587>nvd* RNAi female flies. We found that knocking down of *nvd* resulted in  
175 reduced ovarian ecdysteroid levels compared to that in the control female flies (Fig. 2G). To  
176 confirm whether this reduction is caused by a decrease of NVD enzymatic activity, we  
177 performed a transgenic rescue experiment in the *c587>nvd* RNAi background. As expected, the  
178 levels of the ovarian ecdysteroid were restored upon overexpression of the wild-type *nvd*  
179 ortholog of the silkworm *Bombyx mori* (*nvd-Bm[wt]*), but not its enzymatically dead form  
180 (*nvd-Bm[H109A]*) (Fig. 2G), suggesting that the reduction in ecdysteroid level is not caused by  
181 any off-target effects of the transgenic RNAi. Consistent with this data, the GSC phenotype in  
182 the *c587>nvd* RNAi flies was also rescued by co-expression of the wild-type *nvd-Bm*, but not  
183 the enzyme-dead form (Fig. 2H). To further investigate the role of ecdysteroid on the regulation  
184 of GSC maintenance, we performed a feeding rescue experiment using 7-dehydrocholesterol  
185 (7dC), the downstream metabolite generated by NVD. We found that the *c587>nvd* RNAi  
186 females fed with 7dC did not show a significant decrease in GSC number than the control  
187 female flies. (Fig. 2I). In addition, the GSC number in *c587>nvd* RNAi flies was rescued by the

188 oral administration of 20-hydroxyecdysone (20E), the biologically active ecdysteroid. These  
189 data suggest that ovarian ecdysteroid biosynthesis plays an important role in controlling GSC  
190 proliferation and long-term GSC maintenance in the mated female flies (Fig. 3).

191

## 192 Outlook

193 In conjunction with our previous study,<sup>30</sup> our data suggest that ecdysteroid biosynthesis in the  
194 ovary is differentially regulated in the different life-stages of the female adult fly, including the  
195 post-eclosion and pre-mating stage, the post-mating early stage, and the post-mating late stage  
196 (Fig. 3). In every stage, ecdysteroid biosynthesis plays essential roles in controlling oogenesis,  
197 especially GSC proliferation and/or maintenance. We have confirmed that  
198 ecdysteroid-dependent GSC proliferation in the post-mating stage is controlled by the SP-SPR  
199 signaling pathway, which stimulates the ovarian ecdysteroid biosynthesis via regulation of the  
200 expression of the ecdysteroidogenic enzyme-encoding genes. In contrast, the identity of the  
201 genes and signaling pathways that influence the expression of the enzyme-encoding genes and  
202 the subsequent ecdysteroid biosynthesis in the ovary are unclear. Moreover, the cause of the  
203 fluctuation in ovarian ecdysteroid biosynthesis during the female adult lifespan is not yet clear.  
204 This is in contrast to the fluctuation of ecdysteroid titer that is observed during the embryonic,  
205 larval, and pupal development.<sup>32,33,45</sup> It should be remembered that studies on the role of steroid  
206 hormone biosynthesis in sexual maturation and gametogenesis in the postnatal stage of  
207 mammals has received more attention.<sup>46</sup> In this sense, further studies on ovarian ecdysteroid  
208 biosynthesis in *Drosophila* and other insects would be intriguing to comprehensively  
209 understand the roles of steroid hormone biosynthesis across the animal phyla in the future.

210

## 211 Materials and Methods

212 The flies were raised on cornmeal-agar-yeast media at 25°C. *yw* was used as the control strain.  
213 *SP<sup>0</sup>* and *SP<sup>A</sup>* (ref. <sup>41</sup>) were gifts from Nobuaki Tanaka (Hokkaido University, Japan).  
214 *c587-GAL4* <sup>47,48</sup> was a gift from Hiroko Sano (Kurume University, Japan). Other strains used  
215 were *UAS-nvd-IR*, *UAS-nvd-Bm [wt]*, *UAS-nvd-Bm [H190A]* (ref. <sup>16</sup>). Staining of GSCs with  
216 the 1B1 antibody,<sup>49</sup> quantitative reverse transcription-polymerase chain reaction, and  
217 ecdysteroid measurements were performed as previously described.<sup>30</sup>

218

#### 219 Disclosure of Potential Conflicts of Interest

220 No potential conflicts of interest were disclosed.

221

#### 222 Acknowledgments

223 We thank Reiko Kise, Maki Kashikawa-Yoshida, and Yuko Shimada-Niwa for their technical  
224 support and Katsuo Furukubo-Tokunaga for allowing us to use his microscope. We are also  
225 grateful to Toshiro Aigaki, Nobuaki Tanaka, Hiroko Sano, and the Developmental Studies  
226 Hybridoma Bank for stocks and reagents. TA is a recipient of the research fellowship for young  
227 scientists from the Japan Society for the Promotion of Science. This work was supported by a  
228 grant to TA from the JSPS KAKENHI grant number 15J00652 and by grants to RN from the  
229 MEXT KAKENHI grant number 23116701 (on Innovative Areas ‘Regulatory Mechanism of  
230 Gamete Stem Cells’) and 16H04792 as well as by the JST/PRESTO.

404 Figure legends

405 **Figure 1.** Transcriptional regulation of ecdysteroidogenic enzyme genes in the ovary.

406 (A) The ecdysteroid biosynthesis pathway. Cholesterol is converted into 20-hydroxyecdysone  
407 (active form of ecdysone) by several ecdysteroidogenic enzymes (Shown in bold). (B)

408 Temporal changes in ecdysteroidogenic enzyme genes in virgin female flies in post-eclosion  
409 period (n=4). Most of the genes showed higher expression levels at 6 hours or 15–21 hours

410 post-eclosion (*nobo*, *nvd*, *sro*, *spo*, *phm*, and *shd*). (C) Relative changes in ecdysteroidogenic

411 enzyme gene expression in ovary. Ovaries were dissected from age-matched virgin and mated

412 females at 16 hours post-mating. Some genes showed significant increase in mated female flies

413 compared to virgin female flies (*sro*, *spo*, *phm*, *sad*, and *shd*). These increased expressions after  
414 mating were suppressed when female flies mated with *SP* null male flies (except for *spo*).

415 Values are presented as the mean with standard error of the mean in B. For statistical analysis,

416 t-test with Holm's correction was used for B, Student's t-test was used for C. \*\*\* $P \leq 0.001$ , \*\* $P$

417  $\leq 0.01$ , \* $P \leq 0.05$ , NS, non-significant ( $P > 0.05$ ).

418

419 **Figure 2.** The role of ecdysteroid biosynthesis on the regulation of GSC maintenance.

420 (A) Protocol for all experiments in this figure. One-week-old females were mated with males

421 and used for the assay, 1 week after mating. (B) *Drosophila* germarium. Germline stem cell

422 (GSC) resides in a niche, comprising somatic cells called cap cells, terminal filament, and

423 escort stem cells. GSCs are identifiable by their typical spectrosome morphology and their

424 location (adjacent to the niche cells). GSC produces one self-renewing daughter and one

425 cystoblast (CB) that differentiates into a germline cyst. The cystoblast divides four times with

426 incomplete cytokinesis (2 cc: 2-cell cyst, 4 cc: 4-cell cyst, 8cc: 8-cell cyst and 16 cc: 16-cell

427 cyst). (C) *Drosophila* ovary is composed of 15–20 ovarioles. The continuous developing egg

428 chamber is divided into 14 stages. (D) Left: Frequencies of germaria containing zero, one, two

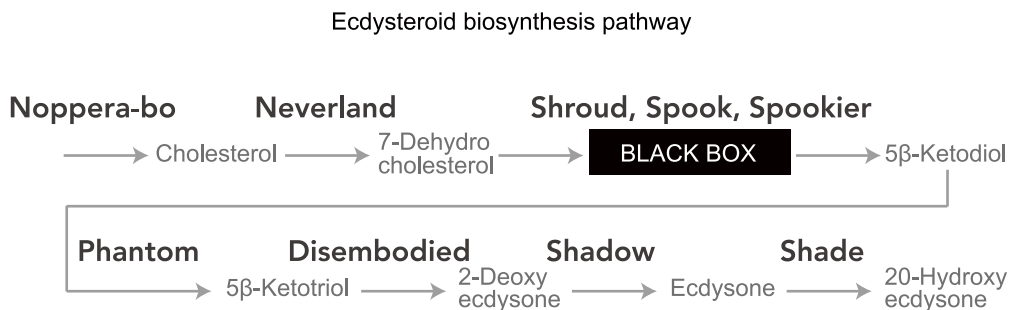

429 and three GSCs (left y-axis), and average number of GSCs per ovarium (right y-axis) in  
430 mated females. Ovarian *neverland* (*nvd*) knockdown in ovarian somatic cells (escort cells and  
431 follicle cells, using *c587-GAL4*) reduced average GSC number as compared to the control ( $P =$   
432 0.006145). Right: Temporal change in GSC number in virgin females (1-day-old and  
433 1-week-old) and mated females (2-week-old), ( $n \geq 94$ ). (E and F) The average number of  
434 germline cyst (E) and egg chamber in each stage (F) was not changed in ovarian *nvd* RNAi  
435 female flies (*c587>nvd RNAi*). (G) *UAS-nvd-Bm [wt]* and *UAS-nvd-Bm [H190A]* were used for  
436 overexpressing the wild-type form and enzymatic inactive form of *Bombyx mori nvd* transgenes,  
437 respectively. Ovarian ecdysteroid decreased in *c587>nvd RNAi* female flies as compared to the  
438 control flies ( $P = 0.0233$ ). This reduction was restored by overexpressing *UAS-nvd-Bm [wt]* but  
439 not *UAS-nvd-Bm [H190A]*. (H) GSC phenotype in *c587>nvd RNAi* animals was restored by  
440 overexpressing *UAS-nvd-Bm [wt]* but not *UAS-nvd-Bm [H190A]*. (I) GSC phenotype in  
441 *c587>nvd RNAi* flies was rescued by oral administration of 20E or 7dC. Values are presented as  
442 the mean with standard error of the mean in G. The numbers of samples examined are indicated  
443 in parentheses in D, E, F, H and I. For statistical analysis, Wilcoxon rank sum test was used for  
444 D, E and F. t-test with Holm's correction was used for G. Steel-Dwass test was used for H and I.  
445 \*\*\* $P \leq 0.001$ , \*\* $P \leq 0.01$ , \* $P \leq 0.05$ , NS, non-significant ( $P > 0.05$ ).

446  
447 **Figure 3.** Model for this study. Ecdysteroid biosynthesis in the ovary is differentially regulated  
448 in different adult life stages, including the post-eclosion and pre-mated stage (upper column),  
449 the post-mating early stage, and the post-mating late stage (lower column). In post-eclosion  
450 stage, ecdysteroidogenic enzyme gene expression is regulated by unknown tropic stimuli and  
451 may be involved in controlling the ovarian ecdysteroid biosynthesis to initiate oogenesis. In  
452 post-mated early stage, SP stimulates ecdysteroid biosynthesis via up-regulation of

453 biosynthesis enzyme gene expression, which control GSC proliferation. Ovarian ecdysteroid  
454 biosynthesis is also required for GSC maintenance in post-mated late stages.
