

DICRITICAL LOGARITHMIC FOLIATIONS

FELIPE CANO AND NURIA CORRAL

Abstract

We show the existence of weak logarithmic models for any (dicritical or not) holomorphic foliation \mathcal{F} of $(\mathbb{C}^2, 0)$ without saddle-nodes in its desingularization. The models are written in terms of a representative set of separatrices, whose equisingularity types are controlled by the Milnor number of the foliation.

1. Introduction

In this paper we show the existence of *weak logarithmic models* for any holomorphic foliation \mathcal{F} of $(\mathbb{C}^2, 0)$ without saddle-nodes in its desingularization (these foliations are called *generalized curves* in [2]). If \mathcal{F} is non-dicritical, the existence of a logarithmic model has been proved in [5] and it gives an approximation of \mathcal{F} by a (logarithmic) foliation with linear projective holonomies given by the linear part of the projective holonomies of \mathcal{F} .

The first difference in the dicritical case is the *choice of the separatrices*. Actually, the logarithmic model should be of the form $\eta = 0$ for

$$\eta = \sum_{i=1}^r \lambda_i \frac{df_i}{f_i}$$

that exhibits the separatrices $f_i = 0$. But there are several possible ways to do this. For instance the foliation $d((y - x^2)/(y + x^2)) = 0$ can also be written down as $d(y/x^2) = 0$. We choose a *representative set* \mathcal{S} of separatrices of \mathcal{F} to get explicitly the closed logarithmic form η . In Theorem 5 it is proved that the possible equisingularity types of \mathcal{S} are bounded by a function of the Milnor number of \mathcal{F} . Note also that the

results in this paper would provide a normalized presentation of a pencil of curves, in terms of multivalued functions.

To have a weak logarithmic model \mathcal{L} for \mathcal{F} roughly speaking means that the reduction of the singularities of \mathcal{L} is longer than the one of \mathcal{F} and coincides with it outside a “escape set” of non-singular points for \mathcal{F} placed at dicritical components (*domination of foliations*). The escape set can be chosen to be a singleton at such dicritical components and this determines the residues λ_i . We prove (Theorem 14) that this concept depends in fact only on the \mathbb{C} -divisor (S, λ) and not on the particular logarithmic foliation we take. This is key in the proof of the existence of weak logarithmic models (Theorems 3 and 16) since it serves to “glue” the models by induction.

We end the paper by a list of examples showing the difficulties in order to get a logarithmic model without escape set.

2. Domination of foliations. Representative sets of separatrices

We consider holomorphic singular foliations \mathcal{F} defined on ambient spaces M of dimension two, equipped with a normal crossing divisor $D \subset M$. As usual, we say that a component F of D is *dicritical* if it is generically transversal to \mathcal{F} ; if F is invariant, we say that it is *non-dicritical*.

The reduction of singularities of \mathcal{F} at $P \in M$ can be done relatively to D as follows. Denote $\text{Sing}(\mathcal{F}, D)$ the set of points $Q \in M$ where \mathcal{F} and D do not have normal crossings; that is, either $Q \in \text{Sing } \mathcal{F}$ or $Q \notin \text{Sing } \mathcal{F}$ but the only invariant curve of \mathcal{F} at Q does not have normal crossings with D . In the case $D = \emptyset$, note that $\text{Sing}(\mathcal{F}, \emptyset) = \text{Sing } \mathcal{F}$. We say that $P \in \text{Sing}(\mathcal{F}, D)$ is *simple for* (\mathcal{F}, D) iff $P \in D$, it is a simple singularity in the sense of Seidenberg [10], [12] and each component of D through P is non-dicritical. Then we have

Theorem (Reduction of singularities [3], [12]). *Let (M, P) be the germ of M at P . There is a finite composition of blowing-ups $\pi = \pi_{(\mathcal{F}, D, P)}: M' \rightarrow (M, P)$ such that, if \mathcal{F}' is the transform of \mathcal{F} by π and $D' = \pi^{-1}(D \cup \{P\})$, then any $Q \in \text{Sing}(\mathcal{F}', D')$ is simple and π is minimal in the sense that it cannot be factorized by another morphism with the above property.*

We call $\pi_{(\mathcal{F}, D, P)}$ the *minimal reduction of singularities of* (\mathcal{F}, D) at P . To get it it's enough to blow-up successively the non-simple points in $\text{Sing}(\mathcal{F}, D)$ (the processus stops by similar arguments to the ones

in [12]). Note that if $D = \emptyset$ the reduction $\pi_{(\mathcal{F}, \emptyset, P)}$ is maybe longer than Seidenberg's reduction; the main difference appears because of the tangencies with the created dicritical components. If \mathcal{F} is non-dicritical (each successive blowing-up is non-dicritical) and $D = \emptyset$, we get essentially the same reduction of singularities as Seidenberg. Even if \mathcal{F} is non-dicritical, the dicritical components of the starting divisor D may produce a longer reduction of singularities; unfortunately, we have to keep them in this paper in order to assure coherence in our induction statements.

Notation. Since \mathcal{F}, D and its reduction of singularities will be fixed, in all this paper we keep the notations $\pi = \pi_{(\mathcal{F}, D, P)}$, $E' = \pi^{-1}(P)$, $D' = \pi^{-1}(D \cup \{P\})$ and we denote $\mathcal{F}', \mathcal{L}', \mathcal{G}'$ the transforms of the foliations $\mathcal{F}, \mathcal{L}, \mathcal{G}$ by π . For a germ of analytic curve Γ at P , we will denote by Γ' the strict transform of Γ by π . Also we shall keep the notation $\pi_1: M_1 \rightarrow (M, P)$ for the blowing-up of (M, P) with center P and we will denote $E_1 = \pi_1^{-1}(P)$ the exceptional divisor, $D_1 = \pi_1^{-1}(D \cup \{P\})$ and $\mathcal{F}_1, \mathcal{L}_1, \mathcal{G}_1, \Gamma_1$ the transforms of objects as above.

Let \mathcal{G} be another singular foliation on M and assume that P is a simple singularity for both (\mathcal{F}, D) and (\mathcal{G}, D) . We say that P has same *linear type of singularity* for (\mathcal{F}, D) and (\mathcal{G}, D) if $I_P(\mathcal{F}, F) = I_P(\mathcal{G}, F)$ for any component F of D through P , where $I_P(\mathcal{F}, F)$ is the Camacho-Sad index (see [1]). In this paper we exclude saddle-nodes at the end of the desingularization, that is, we restrict ourselves to *generalized curves* as defined in [2]; in this case, the indices at simple singularities correspond to the two quotients of eigenvalues.

Definition 1. We say that (\mathcal{G}, D) *dominates* (\mathcal{F}, D) at P if:

- (1) The components of D' are simultaneously dicritical or non-dicritical for the transforms \mathcal{F}' and \mathcal{G}' of \mathcal{F}, \mathcal{G} by π .
- (2) For any non-dicritical component F' of D' we have that

$$\text{Sing}(\mathcal{F}', D') \cap F' = \text{Sing}(\mathcal{G}', D') \cap F'$$

and each $Q \in \text{Sing}(\mathcal{F}', D')$ is a simple singularity for (\mathcal{G}', D') with same linear type and same separatrices as for (\mathcal{F}', D') .

Note that in the case $D = \emptyset$ and \mathcal{F} non-dicritical, we get that $\pi_{(\mathcal{F}, \emptyset, P)} = \pi_{(\mathcal{G}, \emptyset, P)}$ and \mathcal{F}, \mathcal{G} have the same set of separatrices.

Definition 2. Let Γ be a separatrix for \mathcal{F} at P not contained in D . Following [2], we say that Γ is *isolated* for (\mathcal{F}, D) if the strict transform Γ' does not cut E' in a \mathcal{F}' -dicritical component. We say that Γ is an

F' -*curvette* for \mathcal{F} if Γ' cuts E' in a \mathcal{F}' -dicritical component F' . A set \mathcal{S} of separatrices of \mathcal{F} at P is *representative* for (\mathcal{F}, D) if it contains the isolated separatrices, the non-dicritical components of D at P and the number of F' -curvettes in \mathcal{S} for each dicritical component F' of E' is equal to $\max\{0, 2 - v_{D'}F'\}$, where the *valence* $v_{D'}F'$ is the number of components of D' that intersect F' (excluding F').

Note that if \mathcal{F} is non-dicritical the only representative set of separatrices for (\mathcal{F}, D) is the set of all separatrices. In the case of a dicritical \mathcal{F} we know that we have infinitely many separatrices. In order to get a logarithmic model we have to choose *finitely many of them*. The representative sets of separatrices give our choice. The idea is to take not too much “curvettes” to assure that the equisingularity types of the chosen set of separatrices remain bounded by the Milnor number of the foliation (Theorem 5).

This paper is devoted to prove the following theorem:

Theorem 3. *Let \mathcal{F} be a generalized curve of $(\mathbb{C}^2, 0)$ and $\mathcal{S} = \{\Gamma^i\}_{i=1}^r$ a representative set of separatrices for \mathcal{F} . Take a local equation $f_i = 0$ of Γ^i for $i = 1, 2, \dots, r$. Then there are $\lambda_i \in \mathbb{C}^*$, $i = 1, 2, \dots, r$, such that if*

$$\eta = \sum_{i=1}^r \lambda_i \frac{df_i}{f_i}$$

the logarithmic foliation $\eta = 0$ dominates \mathcal{F} .

Let us explain with two examples the definition of a representative set of separatrices. Consider the foliation (Suzuki’s example, see [4]) \mathcal{F} defined by $\omega = (2y^2 + x^3)dx - 2xydy = 0$. It has only one isolated separatrix given by $y^2 - x^3 = 0$. Thus it is not possible to construct a logarithmic foliation written only in terms of the isolated separatrices and dominating \mathcal{F} since it will be non-dicritical. To obtain a logarithmic foliation that dominates \mathcal{F} it is enough to consider the foliation $d((y^2 - x^3)/x^2) = 0$. Note that $\mathcal{S} = \{y^2 - x^3 = 0, x = 0\}$ is a representative set of separatrices of \mathcal{F} . The second example is given by the foliations $\mathcal{F}_{p,q}$ defined by $pxdy - qydx = 0$ with $p, q \in \mathbb{N}$. If $p, q \geq 2$ and $\gcd(p, q) = 1$, then the only dicritical component in the reduction of singularities of $\mathcal{F}_{p,q}$ has valence 2. The curvettes of this dicritical component are the curves $y^p - cx^q = 0$ with $c \in \mathbb{C}$. However, the foliation $\mathcal{F}_{p,q}$ is given by $d(y^p/x^q) = 0$ where $\mathcal{S} = \{x = 0, y = 0\}$ are the isolated separatrices and \mathcal{S} is a representative set of separatrices. Note also that the type of equisingularity of the curves $y^p - cx^q = 0$ is not bounded by a function of the Milnor number since $\mu(\mathcal{F}_{p,q}) = 1$.

Let us give now some properties of a representative set of separatrices.

Proposition 4. *Let \mathcal{F} be a generalized curve at $P \in M$, D a normal crossings divisor and $\mathcal{S} = \{\Gamma^i\}_{i=1}^r$ a representative set of separatrices for (\mathcal{F}, D) . Denote by $C_P\mathcal{S} \subset E_1$ the tangent cone of \mathcal{S} . Then we have*

- (1) $\mathcal{S} \neq \emptyset$, that is $r \geq 1$.
- (2) If \mathcal{S} has only one element and it is non-singular at P , then $P \notin \text{Sing } \mathcal{F}$.
- (3) If π_1 is non-dicritical for \mathcal{F} , then $C_P\mathcal{S} = \text{Sing } \mathcal{F}_1 = \text{Sing}(\mathcal{F}_1, D_1)$.
- (4) If π_1 is \mathcal{F} -dicritical, then $\text{Sing}(\mathcal{F}_1, D_1) \subset C_P\mathcal{S}$.
- (5) If π_1 is \mathcal{F} -dicritical, then $C_P\mathcal{S}$ has $\max\{2, v_D E_1\}$ points.

Proof: (1) If \mathcal{F} is non-dicritical, the result follows from [1]. Note also that the arguments in [1] imply that any connected component of the union of non-dicritical components of the exceptional divisor after reduction of singularities will support at least one isolated separatrix of \mathcal{F} , which is necessarily an element of \mathcal{S} . Thus, it remains to consider the case that all the components of the exceptional divisor are dicritical; since two such components do not intersect, there is only one of them, we are in the radial case and \mathcal{S} has two elements.

(2) If \mathcal{F} is non-dicritical, the result follows from [2], since \mathcal{F} has the same reduction of singularities as the set of separatrices. Moreover, if \mathcal{S} has only one element, then \mathcal{F} must be non-dicritical. To see this, note first that \mathcal{F} is not radial, and hence, by the above arguments, the only element of \mathcal{S} is an isolated separatrix of \mathcal{F} , thus there are no “curvettes” in \mathcal{S} . Then, there is a dicritical component F' with valence greater or equal than two. Now F' cuts at least two connected components of the union of non-dicritical components. This implies the existence of at least two elements in \mathcal{S} in view of the arguments in (1).

(3) It is evident that $C_P\mathcal{S} \subset \text{Sing } \mathcal{F}_1$, since \mathcal{F}_1 has at least two separatrices at the points in $C_P\mathcal{S}$: the exceptional divisor E_1 and the strict transform of an element of \mathcal{S} . To see that $\text{Sing } \mathcal{F}_1 = \text{Sing}(\mathcal{F}_1, D_1)$, take a point $Q \notin \text{Sing } \mathcal{F}_1$, then either $D_1 = E_1$ locally at Q or $D_1 = E_1 \cup F$ and in both cases we have the normal crossings property, since E_1 is invariant. It remains to show that if $Q \notin C_P\mathcal{S}$, then $Q \notin \text{Sing } \mathcal{F}_1$, but this follows from (2) since the only separatrix of \mathcal{F}_1 at Q is the exceptional divisor E_1 .

(4) Take $Q \in \text{Sing}(\mathcal{F}_1, D_1)$. Since E_1 is dicritical, then Q is not a simple singularity for (\mathcal{F}_1, D_1) and thus the reduction of singularities continues through Q . By (1), we get an element of \mathcal{S} passing through Q .

(5) We have that

$$C_P\mathcal{S} = C_P\{E_1\text{-curvettes in } \mathcal{S}\} \cup C_P D \cup \text{Sing}(\mathcal{F}_1, D_1).$$

Moreover, since the points in $\text{Sing}(\mathcal{F}_1, D_1)$ are not simple singularities, we get that the valence $v_D E_1$ is equal to the number of points in $C_P D \cup \text{Sing}(\mathcal{F}_1, D_1)$. The result follows noting that if $v_D E_1 \geq 2$ there are no E_1 -curvettes in \mathcal{S} . \square

Theorem 5. *There is a finite set $\mathcal{E}(\mu)$ for each integer number $\mu \geq 0$ such that the following property holds. Denote by $\mu_P \mathcal{F}$ the Milnor number of \mathcal{F} . Then the equisingularity type of \mathcal{S} is in $\mathcal{E}(\mu_P \mathcal{F})$, for any generalized curve \mathcal{F} and a normal crossings divisor D at $P \in M$, where $\mathcal{S} = \{\Gamma^i\}_{i=1}^r$ is any representative set of separatrices for (\mathcal{F}, D) .*

Proof: By a theorem in [6], the equisingularity types of the union S^* of isolated separatrices and non-dicritical components of D are bounded (in the sense of the statement) by a function of the Milnor number. Now, to get the equisingularity type of a representative set of separatrices we have just to add at most one (or two arrows in the radial case) arrow to the terminal vertices of the dual graphs representing each equisingularity type for S^* . \square

3. Closed logarithmic forms and \mathbb{C} -divisors

Consider a non-empty finite set $\mathcal{S} = \{\Gamma^i\}_{i=1}^r$ of germs of irreducible curves at (M, P) and take a list $\lambda = \{\lambda_i\}_{i=1}^r$ with $\lambda_i \in \mathbb{C}^*$. The pair $\mathcal{D} = (\mathcal{S}, \lambda)$ is called a \mathbb{C} -divisor at P and its *support* is $\text{Supp } \mathcal{D} = \cup_{i=1}^r \Gamma^i$. Write $m_i = \nu_P \Gamma^i$ the multiplicity of Γ^i at P . We say that P is *non-singular* for \mathcal{D} if $r = 1$ and $m_1 = 1$. We say that P is a *simple singularity* for \mathcal{D} if $r = 2$ and $m_1 = m_2 = 1$, the curves Γ^1 and Γ^2 have distinct tangents and $\lambda_1/\lambda_2 \notin \mathbb{Q}_{<0}$. More generally, these definitions can be made relative to a normal crossings divisor $D \subset M$ as follows. We say that P is *non-singular* for (\mathcal{D}, D) if it is non-singular for \mathcal{D} and Γ^1 has normal crossings with D and we say that it is a *simple singularity* for (\mathcal{D}, D) if it is a simple singularity for \mathcal{D} and $\emptyset \neq D \subset \Gamma^1 \cup \Gamma^2$.

Let us define the transform $\mathcal{D}_Q = (\mathcal{S}_Q, \lambda_Q)$ of \mathcal{D} at a point $Q \in E_1$ under the blowing-up $\pi_1: M_1 \rightarrow (M, P)$. Denote I_Q the set of indices defined by the property that $Q \in \Gamma_1^i$ for $i \in I_Q$ and put $\lambda_0 = \sum_{i=1}^r m_i \lambda_i$. Then

$$\begin{aligned} \mathcal{S}_Q &= \{\Gamma_1^i\}_{i \in I_Q}, \quad \lambda_Q = \{\lambda_i\}_{i \in I_Q}, & \text{if } \lambda_0 = 0. \\ \mathcal{S}_Q &= \{\Gamma_1^0 = E_1\} \cup \{\Gamma_1^i\}_{i \in I_Q}, \quad \lambda_Q = \{\lambda_0\} \cup \{\lambda_i\}_{i \in I_Q}, & \text{if } \lambda_0 \neq 0. \end{aligned}$$

Note that if $\mathcal{S}_Q = \emptyset$ then $Q \notin \text{Supp } \mathcal{D}_Q$. This construction can be iterated by blowing-up at points in the support. To be precise, we say that a finite composition of blowing-ups $\sigma: M^* \rightarrow (M, P)$ is a \mathcal{D} -admissible

morphism if the centers of the blowing-ups are in the support of the corresponding transformed \mathbb{C} -divisors. Moreover, we have a reduction of singularities as follows

Proposition 6. *Let $\mathcal{D} = (\mathcal{S}, \lambda)$ be a \mathbb{C} -divisor and D a normal crossings divisor on (M, P) . There is a \mathcal{D} -admissible morphism $\tilde{\pi} = \pi_{(\mathcal{D}, D, P)}: \tilde{M} \rightarrow (M, P)$ such that any point $Q \in \text{Supp } \mathcal{D}_{\tilde{\pi}}$ in the support of the transformed \mathbb{C} -divisor is non-singular or simple for $(\mathcal{D}_{\tilde{\pi}}, \tilde{D})$, where $\tilde{D} = \tilde{\pi}^{-1}(\{P\} \cup D)$ and $\tilde{\pi}$ is minimal in the sense that it cannot be factorized by another morphism with the above property.*

The proof is a consequence of the reduction of singularities of curves and Euclides' algorithm, very similar (but simpler) to the proof in [12].

Consider reduced equations $f_i = 0$ of Γ^i for $i = 1, 2, \dots, r$ and put $f = f_1 f_2 \cdots f_r$. We say that a closed meromorphic 1-form η is (\mathcal{S}, λ) -logarithmic if

$$\eta = \sum_{i=1}^r \lambda_i \frac{df_i}{f_i} + \alpha,$$

where α is holomorphic. In particular α is closed and hence $\alpha = dh$. In fact, we can write $\eta = \sum_{i=1}^r \lambda_i df_i^* / f_i^*$ for suitable local equations $f_i^* = 0$ of each Γ^i (to see this, put $\alpha = du/u$, where $u(P) \neq 0$). Note that if η is (\mathcal{S}, λ) -logarithmic, then $\pi_1^* \eta$ is $(\mathcal{S}_Q, \lambda_Q)$ -logarithmic at $Q \in E_1$.

Definition 7. We say that $\mathcal{D} = (\mathcal{S}, \lambda)$ is a 1-faithful \mathbb{C} -divisor at P if there is a \mathcal{D} -logarithmic 1-form η such that

$$\nu_P(f\eta) = m - 1,$$

where $m = \nu_P f = \sum_{i=1}^r m_i$. (A direct computation shows that this will be then true for any \mathcal{D} -logarithmic 1-form). We say that \mathcal{D} is faithful if its transform is 1-faithful at any point of the support after any \mathcal{D} -admissible morphism.

The non-singular points and the simple singularities are persistent under blowing-up and also the \mathbb{C} -divisor is faithful at this kind of points. Thus in order to verify the faithfulness of \mathcal{D} is enough to verify the 1-faithfulness at the intermediary points in the reduction of singularities.

Lemma 8. *Consider the \mathbb{C} -divisor $\mathcal{D} = (\mathcal{S}, \lambda)$ and let η be a \mathcal{D} -logarithmic 1-form. Denote by \mathcal{L}^η the foliation $\eta = 0$. Put $\lambda_0 = \sum_{i=1}^r m_i \lambda_i$, as above.*

- a) *If $\lambda_0 \neq 0$, then π_1 is non-dicritical for \mathcal{L}^η and \mathcal{D} is 1-faithful.*
- b) *If $\lambda_0 = 0$ and \mathcal{D} is 1-faithful, then π_1 is dicritical for \mathcal{L}^η .*

Proof: First, let us recall that if a foliation \mathcal{G} is given at P by $\omega = 0$, where $\omega = a(x, y)dx + b(x, y)dy$ is a germ of holomorphic form of order t , then π_1 is dicritical for \mathcal{G} if and only if $x\text{In}^t a + y\text{In}^t b = 0$, where $\text{In}^t a$, $\text{In}^t b$ denote the parts of degree t of a , b (here a and b are not necessarily without common factor). Now the part a) of the lemma is an immediate computation, since $f\eta$ is a holomorphic 1-form that gives \mathcal{L}^η . To prove part b), it is enough to note that the fact that \mathcal{D} is 1-faithful means that the initial part of $f\eta$ has degree $m - 1$ and then the condition $\lambda_0 = 0$ is equivalent to the dicriticalness of π_1 . \square

As a consequence, if $\lambda_0 = 0$ and π_1 is non-dicritical, the divisor \mathcal{D} fails to be 1-faithful.

Example 9. Taking $\mathcal{S} = \{y - x^2 = 0, y + x^2 = 0\}$ and $\lambda = (1, -1)$ we get a non 1-faithful $\mathcal{D} = (\mathcal{S}, \lambda)$. In fact $\lambda_0 = 0$ and π_1 is non-dicritical for the foliation $d((y - x^2)/(y + x^2)) = 0$. Note that the same foliation is given by $d(y/x^2) = 0$ and this presentation is faithful. More generally, if the curves of \mathcal{S} have all the same tangent and $\lambda_0 = 0$, we have a non-dicritical blowing-up, as we show next.

Proposition 10. *Assume that the curves of $\mathcal{S} = \{\Gamma^i\}_{i=1}^r$ have all the same tangent at P and that $\lambda_0 = 0$. Take any (\mathcal{S}, λ) -logarithmic form η . Then π_1 is non-dicritical for the logarithmic foliation \mathcal{L} given by $\eta = 0$.*

Proof: Put $f_i(x, y) = y^{m_i} + h_i(x, y)$ with $\nu_P(h_i) > m_i$ for $i = 1, 2, \dots, r$. Take coordinates (u, v) in the second chart of the blowing-up such that $\pi_1(u, v) = (uv, v)$. We can write $f_i = f_i(uv, v) = v^{m_i}(1 + F_i(u, v))$ with $F_i(u, 0) = 0$ and then we have

$$\frac{df_i}{f_i} = m_i \frac{dv}{v} + \frac{dF_i}{1 + F_i},$$

$$\pi_1^* \eta = \sum_{i=1}^r \lambda_i \frac{dF_i}{1 + F_i} = A(u, v) \frac{du}{u} + B(u, v) \frac{dv}{v}.$$

Let us put $M = \max\{k: v^k \text{ divides } A \text{ and } B\}$, $A(u, v) = v^M \tilde{A}(u, v)$ and $B(u, v) = v^M \tilde{B}(u, v)$. To show that $v = 0$ is invariant by $\pi_1^* \eta = 0$ is enough to verify that $\tilde{B}(u, 0) \neq 0$. Since $\pi_1^* \eta$ is a closed form, we have

$$v \frac{\partial A}{\partial v} = u \frac{\partial B}{\partial u}.$$

If v^k divides B , it must also divide $u\partial B/\partial u$ and consequently v^k divides $v\partial A/\partial v$. The hypothesis over the F_i imply that $A(u, 0) = 0$ and thus v^k divides A . We conclude that $M = \max\{k: v^k \text{ divides } B\}$ and then $\tilde{B}(u, 0) \neq 0$. \square

Remark 11 (Mattei). This proof corresponds to the fact that a multi-valued or meromorphic function in $\mathbb{P}_{\mathbb{C}}^1$ with at most either one zero or one pole is constant.

Corollary 12. *Let $\mathcal{D} = (\mathcal{S}, \lambda)$ be 1-faithful. Then $\text{Supp } \mathcal{D}_{\pi_1}$ has at least two points in the exceptional divisor E_1 of the first blowing-up π_1 . As a consequence, if \mathcal{D} is faithful and $\sigma: M^* \rightarrow (M, P)$ is any \mathcal{D} -admissible morphism, then each component F^* of $E^* = \sigma^{-1}(P)$ has at least two points in $\text{Supp } \mathcal{D}_{\sigma}$.*

In the next proposition we recover the relationship between non-dicritical components and support components.

Proposition 13. *Let $\mathcal{D} = (\mathcal{S}, \lambda)$ be a faithful \mathbb{C} -divisor, consider a \mathcal{D} -logarithmic form η , and the corresponding foliation \mathcal{L}^{η} . Let $\sigma: M^* \rightarrow (M, P)$ be any \mathcal{D} -admissible morphism. Then a component F^* of $E^* = \sigma^{-1}(P)$ is non-dicritical for the transform $\mathcal{L}_{\sigma}^{\eta}$ if and only if F^* is contained in the support of the transformed \mathbb{C} -divisor \mathcal{D}_{σ} .*

Proof: It follows just applying the properties of 1-faithfulness at each center in the sequence of blowing-ups. \square

4. Existence of weak logarithmic models

In this section, we consider a generalized curve \mathcal{F} at P , a normal crossings divisor $D \subset M$ and a representative set of separatrices $\mathcal{S} = \{\Gamma^i\}_{i=1}^r$ for (\mathcal{F}, D) at P . We say that a \mathbb{C} -divisor $\mathcal{D} = (\mathcal{S}, \lambda)$ is a *weak logarithmic model* for (\mathcal{F}, D) at P , relatively to \mathcal{S} if and only if we have the following properties:

- (1) \mathcal{D} is faithful.
- (2) $\pi_{(\mathcal{D}, D, P)} = \pi_{(\mathcal{F}, D, P)}$.
- (3) Put $\pi = \pi_{(\mathcal{F}, D, P)}: M' \rightarrow (M, P)$. Then any component F' of E' is dicritical for \mathcal{F}' if and only if F' is not contained in the support $\text{Supp } \mathcal{D}_{\pi}$.
- (4) Any point $Q \in \text{Sing}(\mathcal{F}', D')$ is in the support $\text{Supp } \mathcal{D}_{\pi}$ and the quotient of residues $-\lambda_Q^2/\lambda_Q^1$ is the quotient of the eigenvalues of \mathcal{F}' at Q .

The fact that $\mathcal{D} = (\mathcal{S}, \lambda)$ is a weak logarithmic model for (\mathcal{F}, D) depends only on the projective class $[\lambda] \in \mathbb{P}_{\mathbb{C}}^{r-1}$. Note that $P \in \text{Supp } \mathcal{D}$. Moreover, the definition is compatible with the blowing-ups in the following sense. Take any point $Q \in E_1$ in the support $\text{Supp } \mathcal{D}_{\pi_1}$, then \mathcal{D}_{π_1} is a weak logarithmic model for (\mathcal{F}_1, D_1) at Q .

Theorem 14. *Assume that $\mathcal{D} = (\mathcal{S}, \lambda)$ is a weak logarithmic model for (\mathcal{F}, D) at P , take any \mathcal{D} -logarithmic form η and let \mathcal{L}^η be the foliation $\eta = 0$. Then (\mathcal{L}^η, D) dominates (\mathcal{F}, D) at P .*

Proof: Let us do induction on the number $N_P(\mathcal{F}, D)$ of blowing-ups needed to desingularize (\mathcal{F}, D) at P . Let us consider the case $N_P(\mathcal{F}, D) = 0$. Assume first that $P \notin \text{Sing } \mathcal{F}$. Then the set \mathcal{S} has only one element Γ that is non-singular at P . Take coordinates x, y such that $\Gamma = \{x = 0\}$ and $D \subset \{xy = 0\}$. Note that $\mathcal{D} = (\mathcal{S}, \{\lambda_1\})$ and $x\eta = dx + x\alpha$, for a closed holomorphic form α . Then obviously (\mathcal{L}^η, D) dominates (\mathcal{F}, D) at P . Assume now that $P \in \text{Sing } \mathcal{F}$. Then up to a choice of coordinates we have that $\mathcal{S} = \{\Gamma_1, \Gamma_2\}$, with $\Gamma_1 = \{x = 0\}$, $\Gamma_2 = \{y = 0\}$ and $\Gamma_1 \subset D \subset \Gamma_1 \cup \Gamma_2$. Moreover $-\lambda_2/\lambda_1 \notin \mathbb{Q}_{>0}$ is the quotient of eigenvalues for \mathcal{F} . Then $xy\eta = \lambda_1 y dx + \lambda_2 x dy + xy\alpha$, for a closed holomorphic form α . Then P is a simple singularity for (\mathcal{L}^η, D) with separatrices $xy = 0$ and same quotient of eigenvalues as \mathcal{F} ; the domination is straightforward.

Let us do the induction step. Assume first that π_1 is non-dicritical for \mathcal{F} . Hence $\lambda_0 \neq 0$ and π_1 is non-dicritical for \mathcal{L}^η . Note also that $E_1 \subset \text{Supp } \mathcal{D}_{\pi_1}$. Take a component F of D , to verify if F is dicritical or not for \mathcal{L}^η is enough to do it for the strict transform F_1 of F with respect to \mathcal{L}_1^η ; this one and the rest of the conditions for the domination property can be verified at the points $Q \in E_1$ and this is given by the induction hypothesis.

Assume now that π_1 is dicritical for \mathcal{F} . Then $\lambda_0 = 0$ and in view of the faithfulness π_1 is dicritical for \mathcal{L}^η . Moreover $\text{Supp } \mathcal{D}_{\pi_1} \cap E_1 = C_P \mathcal{S}$. Take a component F of D , if F is non-dicritical for \mathcal{F} , then $F \in \mathcal{S}$ and hence F is non-dicritical for \mathcal{L}^η . Assume that F is dicritical for \mathcal{F} and put $Q_1 = F_1 \cap E_1$, then $Q_1 \in \text{Sing}(\mathcal{F}_1, D_1) \subset C_P \mathcal{S} = \text{Supp } \mathcal{D}_{\pi_1} \cap E_1$ (in view of Proposition 4-(4)). Applying induction hypothesis to Q_1 we deduce that F_1 is dicritical for \mathcal{L}_1^η and hence F is dicritical for \mathcal{L}^η . \square

Let us prove the existence of a weak logarithmic model; in view of the above Theorem 14, this will give the stated Theorem 3.

We need the following computation of Camacho-Sad indices at the non-singular curves of \mathcal{S} . We include a proof for the sake of completeness.

Lemma 15. *Let \mathcal{L}^η be the foliation of $(\mathbb{C}^2, 0)$ defined by $\eta = 0$, with*

$$\eta = \frac{dy}{y} + \sum_{i=2}^r \lambda_i \frac{df_i}{f_i} + \alpha, \quad \alpha \text{ holomorphic, } d\alpha = 0.$$

Then $I_0(\mathcal{L}^\eta, y = 0) = -\sum_{i=2}^r \lambda_i \nu_0(f_i, y)$, where $I_0(\mathcal{L}^\eta, y = 0)$ is the Camacho-Sad index and $\nu_0(f_i, y)$ denotes the intersection multiplicity.

Proof: (See also [9], [11] for the non-dicritical case). We do induction on the number of blowing-ups needed to desingularize \mathcal{L}^η . If the origin is non-singular, then $I_0(\mathcal{L}^\eta, y = 0) = 0$ and $r = 1$. If it is a simple singularity, then $r = 2$ and f_2 is a coordinate $x = f_2$, in this case $-\lambda_2$ is the ratio of eigenvalues that gives the Camacho-Sad index. Now, let us do a blowing-up π_1 and consider the origin P_1 of the first chart, with coordinates $x' = x$, $y' = y/x$. Assume that the $f_i = 0$ tangent to $y = 0$ are those for $i \in B$ and denote $f'_i = x'^{-m_i} f_i \circ \pi_1$ the strict transforms at P_1 of f_i . Now we have

$$\pi_1^* \eta = \frac{dy'}{y'} + \left(1 + \sum_{i=2}^r m_i \lambda_i \right) \frac{dx'}{x'} + \sum_{i \in B} \lambda_i \frac{df'_i}{f'_i} + \alpha^*,$$

where α^* is closed and holomorphic at P_1 . In view of the results of [1], we know that $I_0(\mathcal{L}^\eta, y = 0) = I_{P_1}(\mathcal{L}_1^\eta, y' = 0) + 1$ and by induction hypothesis

$$I_{P_1}(\mathcal{L}_1^\eta, y' = 0) = - \left(1 + \sum_{i=2}^r m_i \lambda_i + \sum_{i \in B} \lambda_i \nu_{P_1}(f'_i, y') \right).$$

We end since $\nu_0(f_i, y) = m_i$ if $i \notin B$ and $\nu_0(f_i, y) = m_i + \nu_{P_1}(f'_i, y')$ for $i \in B$. \square

Theorem 16. *There is a weak logarithmic model $\mathcal{D} = (\mathcal{S}, \lambda)$ for (\mathcal{F}, D) at P , relatively to \mathcal{S} .*

Proof: Let us do induction on $N_P(\mathcal{F}, D)$. The case $N_P(\mathcal{F}, D) = 0$ is done just by looking at the local situations. Let us consider the induction step.

Assume first that π_1 is non-dicritical for \mathcal{F} . Recall that $C_P \mathcal{F} = E_1 \cap \text{Sing } \mathcal{F}_1 = E_1 \cap \text{Sing}(\mathcal{F}_1, D_1)$ and by Proposition 4 we have $C_P \mathcal{F} = C_P \mathcal{S}$. Put $C_P \mathcal{S} = \{P_s\}_{s=1}^k$ and $I_s = \{i; P_s \in \Gamma_1^i\}$. The sets $\mathcal{S}^{(s)} = \{E_1\} \cup \{\Gamma_1^i\}_{i \in I_s}$ are representative sets of separatrices for (\mathcal{F}_1, D_1) at P_s . By induction hypothesis, we get a list of residues $\lambda^{(s)} = \{1\} \cup \{\lambda_i\}_{i \in I_s}$ such that $\mathcal{D}^{(s)} = (\mathcal{S}^{(s)}, \lambda^{(s)})$ is a weak logarithmic model for (\mathcal{F}_1, D_1) at P_s . Let us define $\lambda = \{\lambda_i\}_{i=1}^r$. We are going to show that $\mathcal{D} = (\mathcal{S}, \lambda)$ is a weak logarithmic model for (\mathcal{F}, D) at P . Let $\mathcal{L}^{(s)}$ be a logarithmic foliation defined by a $\mathcal{D}^{(s)}$ -logarithmic form at P_s . Then, by Theorem 14, $I_{P_s}(\mathcal{L}^{(s)}, E_1) = I_{P_s}(\mathcal{F}_1, E_1)$ and by Lemma 15, we have

that $I_{P_s}(\mathcal{L}^{(s)}, E_1) = -\sum_{i \in I_s} \lambda_i m_i$. Thus

$$-1 = \sum_{i=1}^k I_{P_i}(\mathcal{F}_1, E_1) = -\sum_{i=1}^k m_i \lambda_i.$$

Hence $\lambda_0 = \sum_{i=1}^k m_i \lambda_i = 1$ and thus $\mathcal{D}_{\pi_1} = \mathcal{D}^{(s)}$ locally at P_s . Up to apply induction, we have to show the following properties:

- (1) \mathcal{D} is 1-faithful and E_1 is in the support of \mathcal{D}_{π_1} . This follows since $\lambda_0 \neq 0$.
- (2) $\text{Sing}(\mathcal{D}_{\pi_1}, D_1) = \text{Sing}(\mathcal{F}_1, D_1) \cap E_1$. This set is the tangent cone $C_{P\mathcal{S}}$.

Let us assume now that π_1 is \mathcal{F} -dicritical. Take a point $Q \in C_{P\mathcal{S}}$ and consider the set $\mathcal{S}_Q = \{\Gamma_1^i\}_{i \in I_Q}$ corresponding to the curves Γ^i in \mathcal{S} such that $Q \in \Gamma_1^i$. By induction hypothesis applied to (\mathcal{F}_1, D_1) at Q , we get a \mathbb{C} -divisor $\mathcal{D}_Q^* = (\mathcal{S}_Q, \lambda_Q^*)$ that is a weak logarithmic model. Consider $\mu_Q = \sum_{i \in I_Q} m_i \lambda_i^*$ and let us prove that $\mu_Q \neq 0$. Take the 1-form η_Q at P given by

$$\eta_Q = \sum_{i \in I_Q} \lambda_i^* \frac{df_i}{f_i},$$

and assume that $\mu_Q = 0$. Then $\pi_1^* \eta_Q$ defines a \mathcal{D}_Q^* -logarithmic foliation \mathcal{L}_Q^* and, in view of Theorem 14, we know that (\mathcal{L}_Q^*, D_1) dominates (\mathcal{F}_1, D_1) at Q . In particular, the exceptional divisor E_1 is dicritical for \mathcal{L}_Q^* . But this contradicts Proposition 10. Hence $\mu_Q \neq 0$. Now, since $C_{P\mathcal{S}}$ has at least two points (Proposition 4) we can take non-null coefficients ϵ_Q such that $\sum_{Q \in C_{P\mathcal{S}}} \epsilon_Q \mu_Q = 0$. Put $\lambda_i = \epsilon_Q \lambda_i^*$ if $i \in I_Q$. Then the \mathbb{C} -divisor $\mathcal{D} = (\mathcal{S}, \lambda = \{\lambda_i\}_{i=1}^r)$ gives the desired weak logarithmic model. \square

5. The escape set

Assume that $\mathcal{D} = (\mathcal{S}, \lambda)$ is a weak logarithmic model for (\mathcal{F}, D) . Let η be a \mathcal{D} -logarithmic 1-form and \mathcal{L}^η the foliation $\eta = 0$. Two natural questions arise

- (1) Once we have fixed the representative set of separatrices \mathcal{S} , determine the projective classes of λ that give a weak logarithmic model for (\mathcal{F}, D) .
- (2) Determine the “extra singularities” that can appear in the reduction of singularities of (\mathcal{L}^η, D) .

Some answers to these questions are given by the properties of the *escape set*.

Let $\sigma: M^* \rightarrow (M, P)$ be a \mathcal{D} -admissible morphism. Next proposition is devoted to define and give the first properties of the *escape set* $\text{Esc}_\sigma \mathcal{D}$. Let us first define $\text{Esc}_{\sigma, \mathcal{D}}(\eta)$ for a \mathcal{D} -logarithmic 1-form η . We say that $Q \in E^* = \sigma^{-1}(P)$ is in the escape set $\text{Esc}_{\sigma, \mathcal{D}}(\eta)$ if and only if $Q \notin \text{Supp } \mathcal{D}_\sigma$ and $\sigma^*(\eta)$ is either singular or does not have normal crossings with E^* at Q . Note that if $Q \notin \text{Supp } \mathcal{D}_\sigma$ then $\sigma^*\eta$ defines a closed holomorphic form, and hence $\sigma^*\eta = dh$, for a local holomorphic function h at Q .

Proposition 17. *Assume that $\mathcal{D} = (\mathcal{S}, \lambda)$ is faithful and let $\sigma: M^* \rightarrow (M, P)$ be a \mathcal{D} -admissible sequence of blowing-ups. Consider two \mathcal{D} -logarithmic 1-forms η and η^* . Then $\text{Esc}_{\sigma, \mathcal{D}}(\eta) = \text{Esc}_{\sigma, \mathcal{D}}(\eta^*)$. (We call this set $\text{Esc}_\sigma \mathcal{D}$). Moreover, for any component of F^* of $E^* = \sigma^{-1}(P)$ not contained in $\text{Supp } \mathcal{D}_\sigma$ the set $F^* \cap \text{Esc}_\sigma \mathcal{D}$ has at most $k - 2$ points, where k is the number of points in $F^* \cap \text{Supp } \mathcal{D}_\sigma$.*

Proof: Working by induction on the number of blowing-ups, it is enough to prove the following statement:

Assume that the first blowing-up π_1 produces a divisor E_1 not contained in $\text{Supp } \mathcal{D}_{\pi_1}$. Then $E_1 \cap \text{Esc}_{\pi_1, \mathcal{D}}(\eta)$ depends only on \mathcal{D} and has no more than $k_P \mathcal{S} - 2$ points, where $k_P \mathcal{S}$ is the number of elements in the tangent cone $C_P \mathcal{S}$.

Let us prove this statement. Take the precedent notations and assume that

$$\eta = \sum_{i=1}^r \lambda_i \frac{df_i}{f_i} + \alpha,$$

where $0 = \lambda_0 = \sum_{i=1}^r \lambda_i m_i$ and $\nu_P(f\eta) = m - 1$. Up to a choice of suitable coordinates, we may assume that $\text{In}^{m_i} f_i = (y + c^i x)^{m_i}$ with $c^i = c_s$ if $i \in I_s$, where the I_s are pairwise disjoint and $\{1, 2, \dots, r\} = \cup_{s=1}^k I_s$. Note that $k = k_P \mathcal{S}$. Denote n_s the number of elements of I_s . Let us write $f\eta = A dx + B dy$. Note that $x \text{In}^{m-1} A = -y \text{In}^{m-1} B \neq 0$. Moreover $\text{In}^{m-1} B = H(x, y)K(x, y)$, where

$$H(x, y) = \prod_{i=1}^r (y + c^i x)^{m_i - 1} \prod_{s=1}^k (y + c_s x)^{n_s - 1};$$

$$K(x, y) = \sum_{s=1}^k \mu_s \prod_{l=1, l \neq s}^k (y + c_l x)$$

and $\mu_s = \sum_{i \in I_s} \lambda_i m_i$. Note that $K(1, y)$ is a polynomial of degree $\leq k - 2$ (recall that x divides $K(x, y)$). Taking coordinates (x', y') in the

first chart of the blowing-up, the points in the escape set are exactly the points not in the support such that $x' = 0$ and $K(1, y') = 0$, hence, their position depend only on \mathcal{D} and they are no more than $k - 2$. Moreover, if $K(1, y)$ is of degree exactly $k - 2$, then the origin of the second chart is not in the escape set. \square

Consider the transform \mathcal{L}_σ^η of \mathcal{L}^η by σ . Note that \mathcal{L}_σ^η is given by $\sigma^*\eta = 0$. Let F^* be a component of $E^* = \sigma^{-1}(P)$ not contained in $\text{Supp } \mathcal{D}_\sigma$ (recall that in view of Proposition 13 this is equivalent to say that F^* is a dicritical component for \mathcal{L}_σ^η). Consider a point $Q \in F^* \setminus \text{Supp } \mathcal{D}_\sigma$. If $Q \notin \text{Esc}_\sigma \mathcal{D}$ then $\sigma^*\eta$ is non-singular and transversal to F^* and hence $Q \notin \text{Sing}(\mathcal{L}_\sigma^\eta, \sigma^{-1}(P))$. Thus, if we define

$$\text{Esc}_\sigma(\mathcal{L}^\eta) = \text{Sing}(\mathcal{L}_\sigma^\eta, \sigma^{-1}(P)) \setminus \text{Supp } \mathcal{D}_\sigma,$$

we get that $\text{Esc}_\sigma(\mathcal{L}^\eta) \subset \text{Esc}_\sigma(\mathcal{D})$. But the converse is not true, as we will show in some examples.

In the case of a weak logarithmic model, taking $\sigma = \pi$, we see that

$$\text{Esc}_\pi(\mathcal{L}^\eta) = \text{Sing}(\mathcal{L}', D') \setminus \text{Sing}(\mathcal{F}', D').$$

Corollary 18. *For any \mathcal{F}' -dicritical component F' of D' , the number of points in $\text{Esc}_\pi(\mathcal{L}^\eta) \cap F'$ is smaller or equal than $v_{D'}F' - 2$.*

Proof: It is enough to note that for any \mathcal{F}' -dicritical component F' of D' , the points of F' in the support $\text{Supp } \mathcal{D}_\pi$ coincide with the intersections of F' with the other components of D' . \square

In order to get a weak logarithmic model, the escape set $\text{Esc}_\pi \mathcal{D}$ can be fixed to be an arbitrarily chosen point in each \mathcal{F}' -dicritical component F' of E' of valence $v_{D'}F' \geq 3$. Moreover, this produces a unique choice of the projective class of λ . Let us outline the proof of this statement. Take the notations as in the proof of Proposition 17. Recall the polynomial

$$K(x, y) = \sum_{s=1}^k \mu_s \prod_{l=1, l \neq s}^k (y + c_l x)$$

where $\mu_s = \sum_{i \in I_s} \lambda_i m_i$. There is a unique choice of the μ_s such that $K(1, y)$ is a non-null constant polynomial. This gives by induction the desired selection of λ , by putting the escape point at the infinity of the first chart of the blowing-up. More generally, we can fix $v_{D'}F' - 2$ points with multiplicity in each F' to get a unique projective class of λ .

Example 19 (One dicritical blowing-up). The case that we get a non-singular foliation under the first (dicritical) blowing-up has been considered by M. Klughertz [7], [8]. She provides a rational model for the

equisingularity type of the foliation, but her presentation is not in terms of a representative set of separatrices as we propose. In our terms, this case corresponds for instance to foliations having separatrices $f_i = 0$ for

$$f_i = (y + c_i x)^{m_i} + x^{m_i+1}, \quad i = 1, 2, \dots, r.$$

Let us select $\lambda = \{\lambda_i\}_{i=1}^r$ such that the escape set of the \mathbb{C} -divisor is in the infinity. If all the $m_i = n$, one can verify by a long but elementary computation that x^{r-2} divides $f\eta$ and we get as consequence that $\text{Esc}_\pi \mathcal{L} = \emptyset$. Nevertheless, already in the case $m_i = 2$ and $r = 5$, if we consider the separatrices given by $(y + c_i x)^2 + \delta_i x^3 = 0$ for general δ_i , we get $\text{Esc}_\pi \mathcal{L} \neq \emptyset$.

Acknowledgements. We are indebted to J. M. Aroca, J.-F. Mattei and D. Marín for fruitful conversations on the subject. We also thank the referee for his contribution to a good presentation of the paper.
