### **Abstract**

The structure analysis shows that the title compound,  $[\text{TeBr}_2(\text{C}_7\text{H}_7\text{O})_2]$ , is isostructural with the corresponding dichloro compound. There are two molecules in the asymmetric unit in which the Te atom has pseudo-trigonal bipyramidal coordination geometry. The two independent molecules, along with their centrosymmetric equivalents, form isolated tetramers by means of  $\text{Te}\cdots\text{Br}$  contacts ranging from 3.535 (1) to 3.741 (1) Å.

## Comment

As a continuation of our spectroscopic and structural work in the field of organotellurium compounds (Torres, 1990; de Matheus, Torres, Piniella, Briansó & Mira-vitilles, 1991; Farran, Alvarez-Larena, Piniella, Germain & Torres, 1994), we have determined the structure of the title compound, (I).

The structure found for the title compound confirms the results of previous spectroscopic studies:  $^1\text{H}$  NMR (Berry, Kustan, Roshani & Smith, 1975; Ley, Meerholz & Barton, 1981),  $^{13}\text{C}$  NMR (Chadha & Miller, 1982), low-frequency IR (McWhinnie & Patel, 1972) and  $^{125}\text{Te}$  Mössbauer (Berry & Jones, 1976).

The two independent molecules present in the asymmetric unit have similar conformations, differing mainly

in the orientation of one methoxy group ( $O_3$ —C37). The phenyl rings are in a propeller arrangement. The intramolecular geometry around the Te atoms is pseudo-trigonal bipyramidal, with Br atoms in the apical positions and the Te lone pair occupying the fifth position in the equatorial plane, as expected for a non-ionic  $R_2TeX_2$  compound (Mangion, Zingaro & Meyers, 1975). Dibromobis(4-methoxyphenyl)tellurium displays the longest and the shortest Te—Br bond lengths when compared with the other known structures having a  $C_2$ —Te—Br<sub>2</sub> subunit (Christofferson & McCullough, 1958; Chadha & Nguyen, 1990; Knobler & McCullough, 1972; Detty & Luss, 1986). The length of the Te—Br bond depends on the intermolecular contacts. Three situations are found: firstly, when the Br atoms do not participate in any interaction the distance is the shortest [Te2—Br3 2.629 (1) Å]; second, when a Br atom is involved in one intermolecular contact with another Te atom, the distances are intermediate [Te1—Br1 and Te1—Br2 2.672 (1) and 2.677 (1) Å, respectively]; and third, when a Br atom forms two Te···Br contacts, the Te—Br distance is the longest [Te2—Br4 2.733 (1) Å]. The Te—C distances [2.110 (4)–2.116 (4) Å] are at the lower end of the range observed for the aforementioned dibromo compounds. Another interesting feature is that the Br—Te—Br angles [179.12 (2) and 179.44 (2)°] are closer to the ideal value of 180° than in the other structures.

Taking into account the intermolecular contacts, the coordination around the Te atoms may be considered to be octahedral. The title compound is isostructural with the dichloro analogue  $[\text{TeCl}_2(\text{C}_7\text{H}_7\text{O})_2]$  (Chadha & Drake, 1984). The packing consists of isolated tetramers formed by the two molecules of the asymmetric unit and the two generated by a centre of symmetry. The four molecules are connected through  $\text{Te}\cdots\text{Br}$  contacts. This pattern is similar to that seen for  $[\text{TeCl}_2(\text{C}_6\text{H}_5)(p\text{-BrC}_6\text{H}_4)]$  (Chadha, Drake & Khan, 1983) and  $[\text{TeCl}_2(\text{C}_{12}\text{H}_8\text{O})]$  (Korp, Bernal, Turley & Martin, 1980).

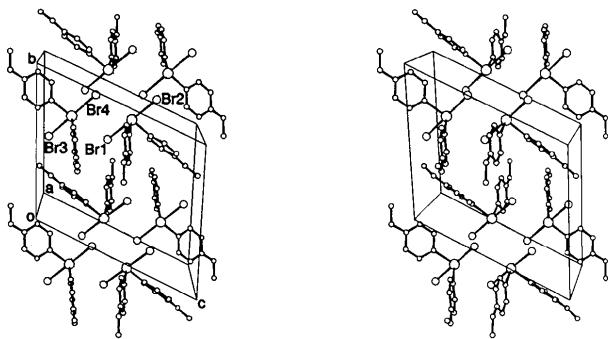

Fig. 2. Stereoview of the unit-cell packing showing the tetramers.

## Experimental

The compound was synthesized according to the method of Lederer (1916) and suitable crystals were grown by slow evaporation from an acetone solution.

### Crystal data

[TeBr<sub>2</sub>(C<sub>7</sub>H<sub>7</sub>O)<sub>2</sub>]

$M_r = 501.67$
