A DESIGN OF FEEDING NETWORK FOR A DUAL-LINEAR POLARIZATION, STACKED, PROBE-FED MICROSTRIP PATCH ANTENNA ARRAY

Grzegorz Jaworski, Viktor Krozer*

Abstract: Components of multilayer feed network are presented for application in broad-band dual-linear polarized stacked C-band antenna. Measurement results of wide band matching circuits and different types of power divider networks constituting parts of BFN demonstrate wideband operation. Suitable matching of individual patches as well as stripline transitions have been developed.

Introduction

Microstrip Patch antennas are widely used in modern communication, radar and aerospace systems [1], [2]. In some systems, like synthetic aperture radar (SAR) dual frequency operation and dual-linear polarization, with low cross-polarization capability are desired. Also additional requirements for low side-lobes, cos^2 radiation pattern and wide-band operation result in complex design of an antenna beam forming network (BFN) design. The feeding network has to incorporate matching circuits enabling matched wide band operation of antenna elements together with different types of power dividers/combiners providing proper, usually non-uniform, power distribution to antenna elements. To provide dual-linear polarization capability with low cross-polarization coefficient good isolation between the individual parts of the BFN must be assured. All these requirements suggest an application of multilayer structure where different parts of BFN are placed on different layers and good isolation can be easily achieved, when stripline technology is applied. Multilayer structure requires a number of interconnections between layers (vias). The possibility of excitation of leaky modes that can significantly deteriorate properties of BFN must be taken into account. In this paper we present the design of such a multilayer BFN for a C-band dual-linear polarized antenna for radar application.

The BFN arrangement

The antenna discussed in this paper operates in C-band and is part of the dual-frequency dual-linear polarization antenna array presented earlier in [3]. The antenna consists of 3×64 radiating elements arranged in 8×8 element array. Each element is fed by two probes one for horizontal and one for vertical polarization. The feeding probe positions are rotated to provide low cross-polarization and low sidelobes by the method invented in DTU [4] and are presented in Fig. 1.

A cos^2 pattern is demanded in elevation plane. As a result the power distribution is non-uniform and the signal delivered to each column of antenna array must have different amplitude and phase. In Fig. 2 the arrangement for the feeding network in elevation plane is presented together with the desired excitation coefficients. The scheme of this part of BFN is identical for both horizontal and vertical polarization. In azimuth plane the uniform power distribution have been chosen, however because of the special positioning of feeding probes 180 deg phase shift must be provided in the power divider network. As a result in azimuth plane the feeding networks for horizontal and for vertical polarizations have different layouts. This is presented in Fig. 3.

Matching circuits.

In the dual-frequency stacked microstrip patch antenna configuration a matched bandwidth of less than 5% is achievable due to the restrictions in the substrate thickness of the layers and the necessity of sharing substrates [3]. High-resolution SAR systems demand antenna arrays with wideband (around 8% or larger relative bandwidth) and low return loss (≤ 15 dB) capabilities, exceeding the operational bandwidth of microstrip antennas without impedance matching structures. To meet these requirements a novel approach for the matching of individual antenna elements of an antenna array has been applied [5]. The layout of the matching circuit and the measured results are presented in Fig. 4.

Power dividers/combiners.

In elevation plane highly non-uniform power distribution is required for the realization of cosec^2 radiation pattern. Consequently, the power division network consists of different types of power splitters providing various power division ratios. For moderate power division ratio (-8.6 dB) the Gysel-type power dividers have been applied to overcome the problem with very high and very low transmission line characteristic impedances that appears in Wilkinson's power dividers [6]. For high power splitting two directional couplers providing -21,6 dB and -25,4 dB coupling have been applied. In Fig. 5 the layout of 1 to 8 power divider is presented. To realize the uniform power distribution in azimuth plane the standard Wilkinson's type and hybrid ring power divider have been designed. The hybrid ring provide the desired 180 deg phase shift between adjacent antenna elements. The layouts of power dividers for horizontal and vertical polarization are presented in Fig. 7 and measured performance in Fig. 8.

Connections between layers

Numerous vias have to be employed in order to assure necessary connections between BFN parts placed on different layers. Some of these are buried inside the structure and not accessible after manufacturing. By proper design of manufacturing sequence it is possible to provide necessary access during the manufacturing process. Presence of via discontinuity in multilayered environment creates the possibility of launching leaky modes [7]. As a result significant crosstalk to other lines and deterioration of via transmission loss appears. This phenomenon is not clearly visible from return loss characteristics. Several techniques for suppression of those parasitic modes have been reported [7], [8]. In the present BFN design, novel type of strip-vias with additional

grounding strips illustrated in Fig. 9 have been applied. This technique successfully inhibits the excitation of leaky modes which leads to a significant reduction of via transmission loss.

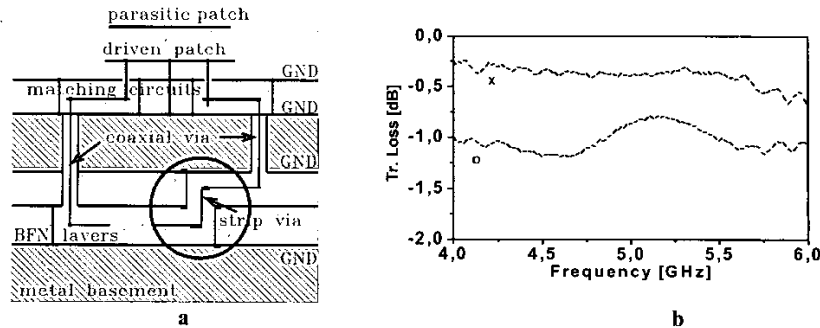

Fig. 9 The cross-section of multilayer antenna structure. In the circle cross section of strip via with two additional strips connected to ground planes is presented b) comparison of measured transmission loss for strip via with (x) and without (o) additional grounding strips

Conclusion

The paper presents a successful broadband design of a beamforming network for 8 x 8 antenna array at C-band. The BFN employs novel approaches in antenna matching and stripline via structure. The BFN is realised in multilayer strip-line technology on Rogers RT 5870 substrate. The overall BFN parameters are summarized in Table 1.

Bandwidth (VSWR ≤ 1.5)	$f_c \pm 200$ [MHz]	S/M
Overall loss of BFN from input to antenna element	2.5 [dB]	S/M
Return Loss at input	VSWR ≤ 1.5 in (5.2 ÷ 5.8) [GHz]	M
Return loss at antenna element	VSWR ≤ 1.5 in (5.21 ÷ 5.85) [GHz]	M
Overall radiation efficiency	47%	S

Table 1. BFN parameters. S-simulated (Agilent ADS or Momentum), M- measured
