**DESCRIPTION OF THE RISØ PUFF DIFFUSION MODEL**

**Torben Mikkelsen**

**Abstract.** The Risø National Laboratory, Roskilde, Denmark, atmospheric puff dispersion model is described. This three-dimensional model simulates the release of Gaussian pollutant puffs and predicts their concentration as they are diffused and advected downwind by a horizontally homogeneous, time-dependent wind. Atmospheric characteristics such as turbulence intensity, potential temperature gradient, buoyant heat flux and maximum mixing depth have been considered.

**INIS descriptors:** ADVECTION; AIR POLLUTION; BOUNDARY LAYERS; CLUSTER EMISSION MODEL; COMPUTERIZED SIMULATION; DIFFUSION; EARTH ATMOSPHERE; HEAT FLUX; METEOROLOGY; PLUMES; SPATIAL DISTRIBUTION; TEMPERATURE INVERSIONS; TRAJECTORIES; TURBULENCE; WIND

## 1. INTRODUCTION

The downwind transport and distribution of atmospheric pollutants from a isolated source over land or water has become an important environmental factor in today's society. The need to understand the distribution of smoke, unpleasant or potentially harmful foreign gases and perhaps radioactive debris from a nuclear power plant accident are becoming more and more essential for industrial operations and construction planning. The dispersion of such atmospheric pollutants is commonly modeled by a standard Gaussian plume model which computes one-hour average plume characteristics.

The Meteorology Section of the Risø National Laboratory, Roskilde, Denmark, has recently developed a puff model for prediction and simulation of atmospheric pollutant diffusion.

The model considers individual puffs of pollutants with specific release rates that are advected by a horizontally homogeneous wind over a grid. The wind input may be either the measured wind from a single point, a spatial average or a wind simulation. The model simulates the instantaneous plume characteristics by adding a group of puffs, growing in size, as they advect with the wind. A Gaussian plume model, on the other hand, provides a time averaged concentration pattern based on a single time average wind vector. In the puff model, the plume advects with a time series of actual wind data. Thus, the puff model is able to predict time varying concentration distributions in actual changing wind conditions, making it an appropriate tool for dynamical computations of downwind dispersions of pollutants.

A basic comparison of a puff model simulation and a typical plume is illustrated in Fig. 1. Looking from above, the instantaneous behaviour of a plume being advected from a source by the wind is shown. The outer cone-shaped contours represent the outer limit of the plume boundary and are identical in both Figs. 1 (A) and (B).

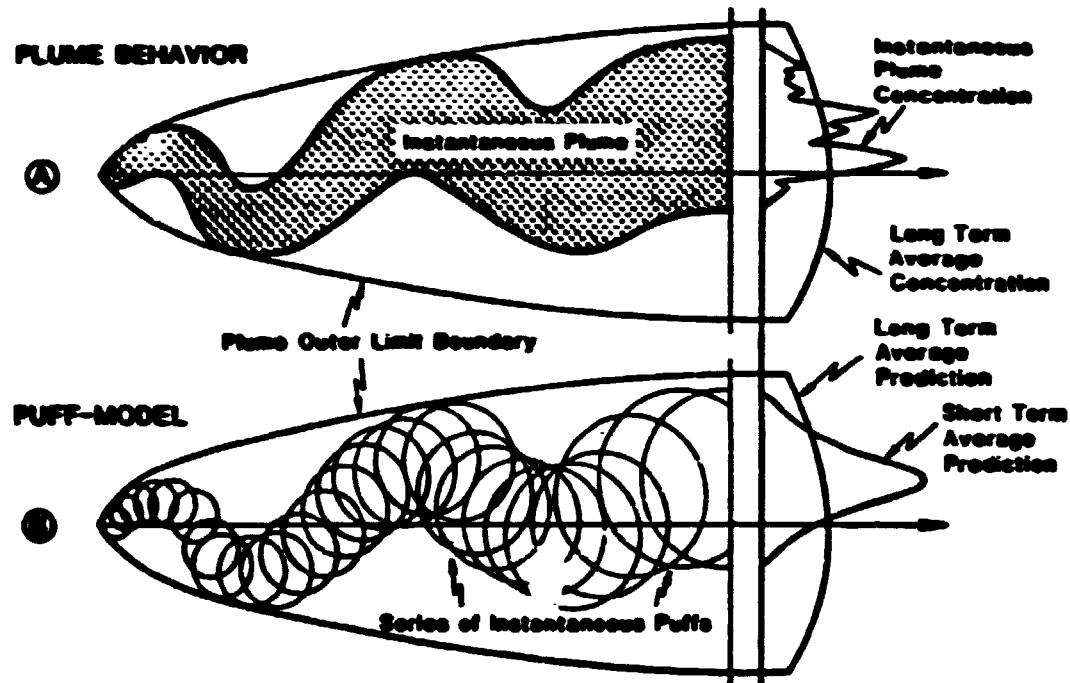

Fig. 1. Instantaneous behaviour of typical plume and a series of puffs from a puff model.

Fig. 1(A) shows an instantaneous depiction of an actual plume. The long-term average plume concentration is shown on the extreme right as a smooth curve with a maximum on the central axis. Also shown is the instantaneous plume concentration considered realistic but is of such a short time scale that it cannot be predicted or easily measured.

The puff model prediction is depicted in Fig. 1(B). The circles show the boundaries of individual puffs of pollutants released from the source. These puffs are advected and diffused downwind by a frequently updated wind. The long term average concentration prediction of the puff model is expected to be identical to the long term concentration of Fig. 1(A). The short term average pollutant prediction, a Gaussian curve shown on the extreme right, is not completely realistic but is a reasonable approximation to the instantaneous plume concentration profile.

## 2. RISO PUFF MODEL

### 2.1 General characteristics

The Riso puff model is a three-dimensional computer model used for the prediction and/or simulation of the diffusion and advection of atmospheric pollutants. The puff model technique is to simulate a plume with Gaussian shaped puffs with specified release rates within a specified grid. The initial size of the puffs is normally one meter in diameter although this can be easily adjusted. The amount of material in a puff is the release rate times the elapsed time between puffs. Therefore, a long elapsed time between puff releases results in a higher initial puff pollutant concentration than a short time interval. This should not normally be of concern if an adequate balance is maintained between grid size, advection speed and puff release

The location of the puffs on the grid is determined by computing their movement for a finite time step using a measured wind field. The growth and buoyancy of the puffs are computed from simultaneous specifications of atmospheric turbulence intensity and stability and from buoyant heat flux at the source. An inversion cap through which pollutants cannot pass and the source height where pollutants are released are variable and can easily be adjusted. Grid distances within the model may vary from meters to kilometers and time durations from seconds to hours are possible.

This puff model has the capability of monitoring a maximum of twenty-five sources of puffs and its grid may contain up to 100 puffs. A puff source can be located anywhere on the grid and have a unique release rate, start and stop of release time, and heat production. When the center of a puff moves outside the boundaries of the grid (either horizontally or vertically), that particular puff is dropped from memory. In this way the model does not store irrelevant puff information, thus keeping computer memory requirements to a minimum.

A variable to control the amount of reflection/absorption of the pollutant by the surface is easily adjusted in the puff model. Such a parameter is of great value both in actual dispersion problems and also for gaining understandings of the plume/surface relationship.

The model calculates the concentration at each grid point by summing the contributions from surrounding puffs for each advection step. The grid concentrations can be allowed to accumulate or simply be updated with the latest instantaneous value. A minimum grid concentration of interest can be set to reduce computer run time by dropping concentrations too small to be of interest.

The output of the model contains periodic results of puff locations and concentrations as well as initial input verification. The time interval for the periodic results is adjusted by the input data. This recurrent lineprinter output contains:

- X-Y plane plots showing the position of the sources and of puffs inside the grid,
- X-Z plane plots of puff positions for evaluating plume rise for each vertical level of interest, and
- a table listing of the grid point concentrations for each level.

A computer drawn contour of the magnitudes of the pollutant concentrations is also available.

When considering distance between gridpoints (delta X,Y,Z), only spatial resolution and computer resources need be considered, calculated concentrations accuracy is not related to the grid-point separation. To ensure that no essential information on individual puffs is "hidden" between grid points, the grid separation should be adjusted dependent upon the size

of the puffs at the downwind distance of interest. Other specific model configuration considerations are described in the following sections. They are also discussed in more detail in the model behaviour chapter.

## 2.2. Wind field

Once a puff is released, it is advected based upon wind data measurements at a single point only, normally the release point. This limits the validity of the model to situations where the wind field and turbulence can be assumed to be horizontally homogeneous throughout the grid. It is therefore important to ensure that the data obtained from such a single point measurement is representative of the wind structure for the whole area of interest.

The wind data are normally obtained in the form of a horizontal velocity time series. A vector sequence is formed by averaging over a convenient interval. These data are read into the model after being segregated into turbulence classes as discussed in the next section.

## 2.3 Turbulence intensity and diffusion

The growth/diffusion of a puff depends upon the turbulence intensity. To account for this growth, the puff model applies the theory for relative diffusion suggested by Smith and Hay (1961).

The turbulence intensity is defined to be the standard deviation of the wind direction (in radians) squared. These standard deviation values are collected for the same short time periods as the wind speed measurements used to advect the puffs. Therefore, the intensity of the turbulence which governs the relative diffusion of the puffs, can be adjusted along with the advecting wind speed after each time step, if the stability conditions changes.

A very low value of turbulence intensity represents a small standard deviation, normally a stable atmosphere and a weak puff dispersion/diffusion. As the atmosphere becomes more unstable, the turbulence intensity increases along with an increase of the wind direction standard deviations and plume dispersion/diffusion. While these characteristics are representative of turbulence over land, they can be applied to over water cases in a broad sense.

#### 2.4 Plume rise

In the vertical direction, puff-rise can be accounted for by Briggs (1970) plume rise theory. In this case buoyancy is assumed to be conserved (adiabatic motion), and pressure forces, molecular viscosity and local density changes are considered small and are neglected. The rate at which a puff rises as it is advected downwind is a function of the buoyancy flux, wind speed, puff distance travelled and stability of the atmosphere. Plume rise is considered separately for each individual puff.

#### 2.5 Reflection

The interaction of the pollutant with the surface is adjustable and can be easily changed in the input data. Total reflection or absorption or a fraction between the two can be used.

#### 2.6 Limit of mixing depth

The effect of an atmospheric lid (inversion) can be applied in the model to limit the vertical movement of the pollutant. The model does not permit the plume to rise above this cap. When a mixing level is in effect, it acts to totally reflect the pollutant in the same manner as total reflection at the surface. This mixing cap also acts as an inversion limiting the vertical diffusion of a non-buoyant puff.

3. ACKNOWLEDGMENT

Stephan K. Rinard, The Naval Postgraduate School, Monterey, California is grateful acknowledged for, in connection with his master thesis: "An analysis of a puff dispersion model for a coastal region", to significantly improve the previous description of the Riss puff model (Mikkelsen, T. (1979) Simulation of obscuration smoke diffusion, 73 pp).

## APPENDIX A

### Major Sections of the puff model

The Riso puff model code has previously been described Mikkelsen, T. (1979). The code also is well documented with comment statements. With that information and the outline to be provided in this and the following appendices, the computational and input/output procedures will be obvious.

The program and input data are stored on cards for the sake of permanency. For efficient operational execution, the program and input data cards are read on a disk within the computer. The model can then be run at will without reference to the original data cards. Minor changes can easily be made directly on the disk both to the model and/or data before each execution.

The model can be separated into the following main sections:

- a) Input data
- b) Initial
- c) Calculating
- d) Output
- e) Error diagnostics
- f) Subroutines

These will be described separately in the following sections.

A. Input data section

The input data includes the variables shown in Table IV.

Table IV

**Input Data Variables for the Puff Dispersion Model**

Wind History	Potential Temperature Gradient
Turbulence Intensity	Buoyant Heat Flux
Grid Dimensions	Minimum Concentration of Interest
Mixing Depth	Reflection at Ground Level
Source Locations, Start/Stop Time, Strength, Heat Emission, Number of Seconds between Advection Steps	
Number of Secoands between Printouts/Plots	
Number of Seconds between Puff Releases	

The wind field and stability class for the current time step are read at the start of the calculation section.

The variables listed above are printed as input data check and a permanent record to accompany the actual output. In most cases the print command can be overridden by YES/NO options.

B. Initial section

Based upon the input data from section (A), the initial section specifies and initializes parameters to be used in the calculating section and is passed only once during execution of the model. The grid and some counters are initialized. Constants relating to reflectance, mixing depth and stability as well as those controlling the size of some of the loops within the model are established. Parameters such as number of puff releases per second, number of advection steps per second and number of advectionb steps per puff release are determined.

C. Calculation section

Using current wind and stability class data read at the start of the calculation section, the model advects the puff centers and calculates the growth rate and plume rise of the puffs. It removes the puffs that have left the grid (horizontally and/or vertically). The predicted concentration is computed at the grid points to include pollutants from all nearby puffs.

D. Output section

For time intervals designated by the input data, printer plots of the X-Y and Y-Z grid are produced. A maximum mixing level is marked on the Y-Z grid if in effect.

These plots include the source location and a trace of the plume from the release time to the maptime. Also printed at this interval is a X-Y table of grid concentrations for each vertical level of interest. These concentrations can be either accumulated or actual concentrations at the plot time.

Added to the puff model is a versatile plotter routine to smooth and contour the grid magnitude concentrations of the above tables.

E. Error Diagnostic section

If the model is directed by the input data beyond the limits of the design of the program, the program is terminated by way of the error diagnostic section. It prints comments relating to the commonly made input errors enabling the user to isolate problems.

F. Subroutines

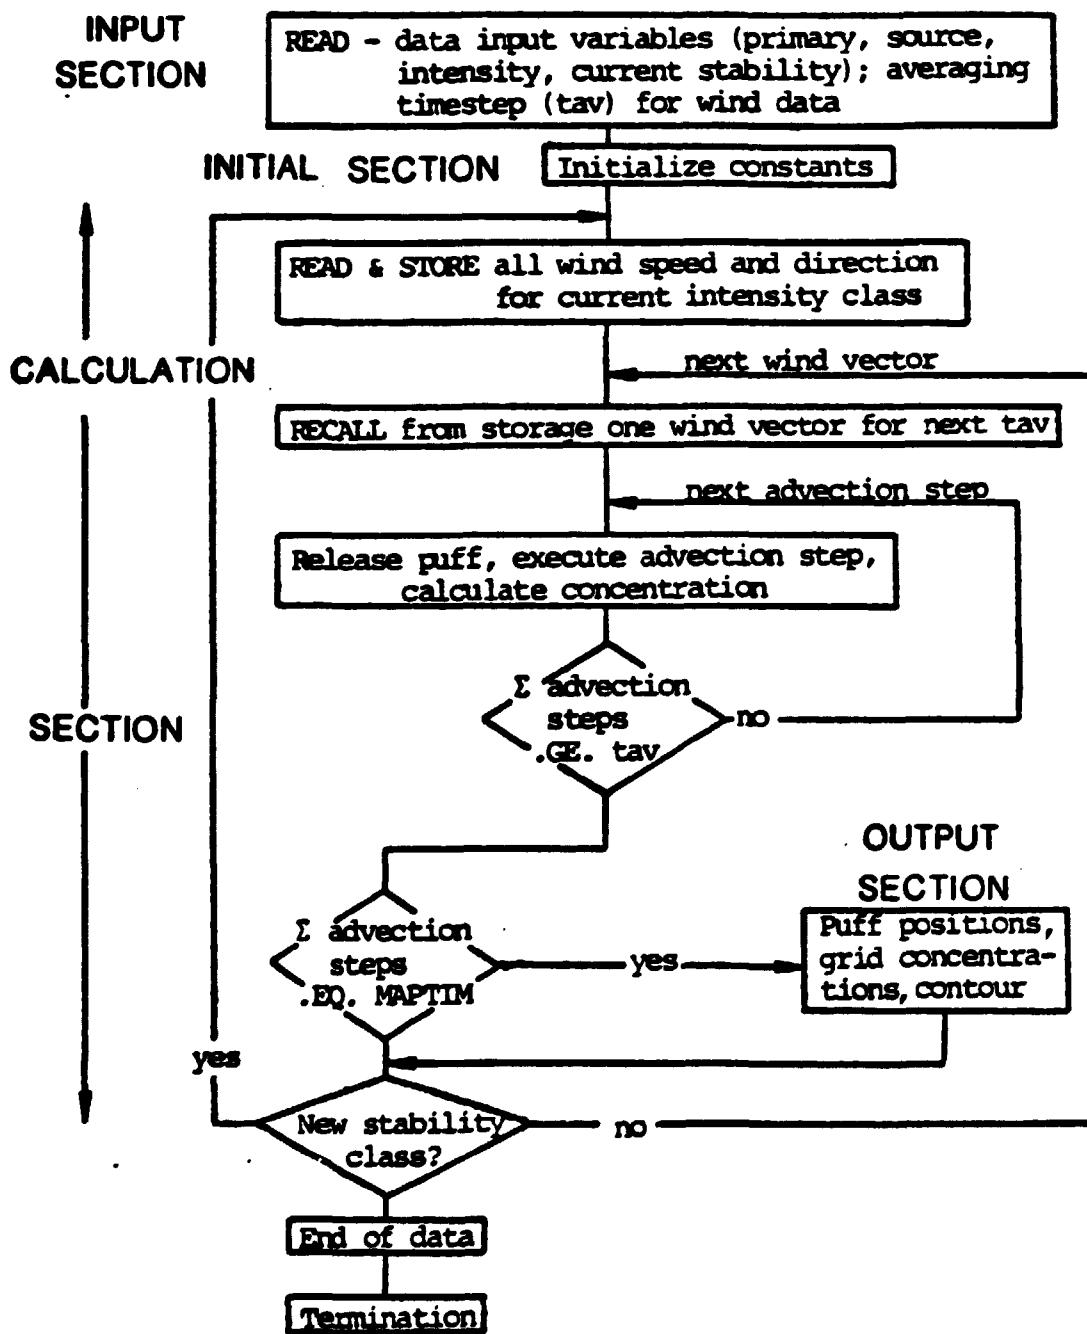

The subroutine "Sigris" calculates the puff size in the horizontal and vertical directions. It also estimates plume rise associated with pollutant buoyancy.

The subroutines "Ispace" and "Rspace" are used in the framework of the printer plots.

The subroutine "Plout" converts the plume concentrations to a logarithmic values, smoothes and then contours them using Risø inhouse contour subroutines. The values are converted to their logarithm values so that the problem of contouring over many orders of magnitude is simplified.2A

APPENDIX B

PUFF MODEL FLOW CHART

APPENDIX C

Puff Model Concentrations

CHEMIN -- Minimum grid concentration of interest  
DELX, DELY, DELZ -- Distance in meters between grid points  
DOSE -- Allows the concentration matrix to accumulate  
DTDZ -- Potential temperature gradient (K/m) (.GE. 0)  
HEAT -- Individual source heat emission (KWatt)  
ICOLS -- Number of columns in grid (.LE. 10)  
INST -- Instantaneous concentration matrix  
ITIME -- Start time  
JROWS -- Number of rows in grid  
KPLANS -- Number of vertical levels in grid (includes surface)  
MAPTIM -- Number of seconds between printer plots  
NRELSE -- Number of seconds to stop of release  
NRMULT -- Number of sources (.LE. 25)  
NTADV -- Integer number of seconds between advection steps  
REFLEC -- Reflection at ground level (0. none; 1.0 total)  
SOURNR -- Number to identify source  
SOURST -- Strength for individual source (g/s)  
STOPRL -- Individual stource stop time (s)  
STRTRL -- Individual source start time (s)  
TAU -- Integer number of seconds between puff releases  
TURN -- Angle of rotation of wind direction  
XSOURCE -- X coordinate of source in grid units  
YSOURCE -- Y coordinate of source in grid units  
ZM -- Limited mixing depth (m)

Risø - M -

Title and author(s)		Date October 1982
Description of the Risø puff diffusion model		Department or group
Torben Mikkelsen		Physics Dept.
		Group's own registration number(s)
43 pages + tables + illustrations		
<b>Abstract</b>		Copies to
The Risø National Laboratory, Roskilde, Denmark, atmospheric puff dispersion model is described. This three-dimensional model simulates the release of Gaussian pollutant puffs and predicts their concentration as they are diffused and advected downwind by a horizontally homogeneous, time-dependent wind. Atmospheric characteristics such as turbulence intensity, potential temperature gradient, buoyant heat flux and maximum mixing depth have been considered.
