## Introduction

- Rapid sand filtration is used in drinking water treatment to remove particles and inorganic compounds such as  $\text{NH}_4^+$ ,  $\text{Fe}^{+2}$  &  $\text{Mn}^{+2}$
- $\text{NH}_4^+$  is removed biologically by microorganisms attached on the sand
- About 25% of waterworks in Denmark exceed the effluent  $\text{NH}_4^+$  guideline of 0.05 mg/L.
- Loading can often change due to switching between abstraction wells with different water quality
- Loading that exceeds a filter's removal capacity may cause transient ammonium breakthrough

### Research question:

In which operating region have  $\text{NH}_4^+$  loading changes no effect a filter's performance?

## Objectives

- Investigate the relationship between  $\text{NH}_4^+$  loading and effluent  $\text{NH}_4^+$  concentration in a filter
- Identify the loading region where loading changes do not affect effluent concentration

Figure 1: Sketch of nitrification in a rapid sand filter. Ammonium is degraded by a nitrifying biofilm attached on the sand grain surface

## Conclusions

- $\text{NH}_4^+$  loading variations below the critical loading had no effect on effluent  $\text{NH}_4^+$  concentration
- Once the critical loading was exceeded, effluent  $\text{NH}_4^+$  concentration was strongly affected by loading increases
- For the investigated filter, the critical load was 5 times larger than the operating load. Performance of this filter is expected to be robust against load variations

## Method

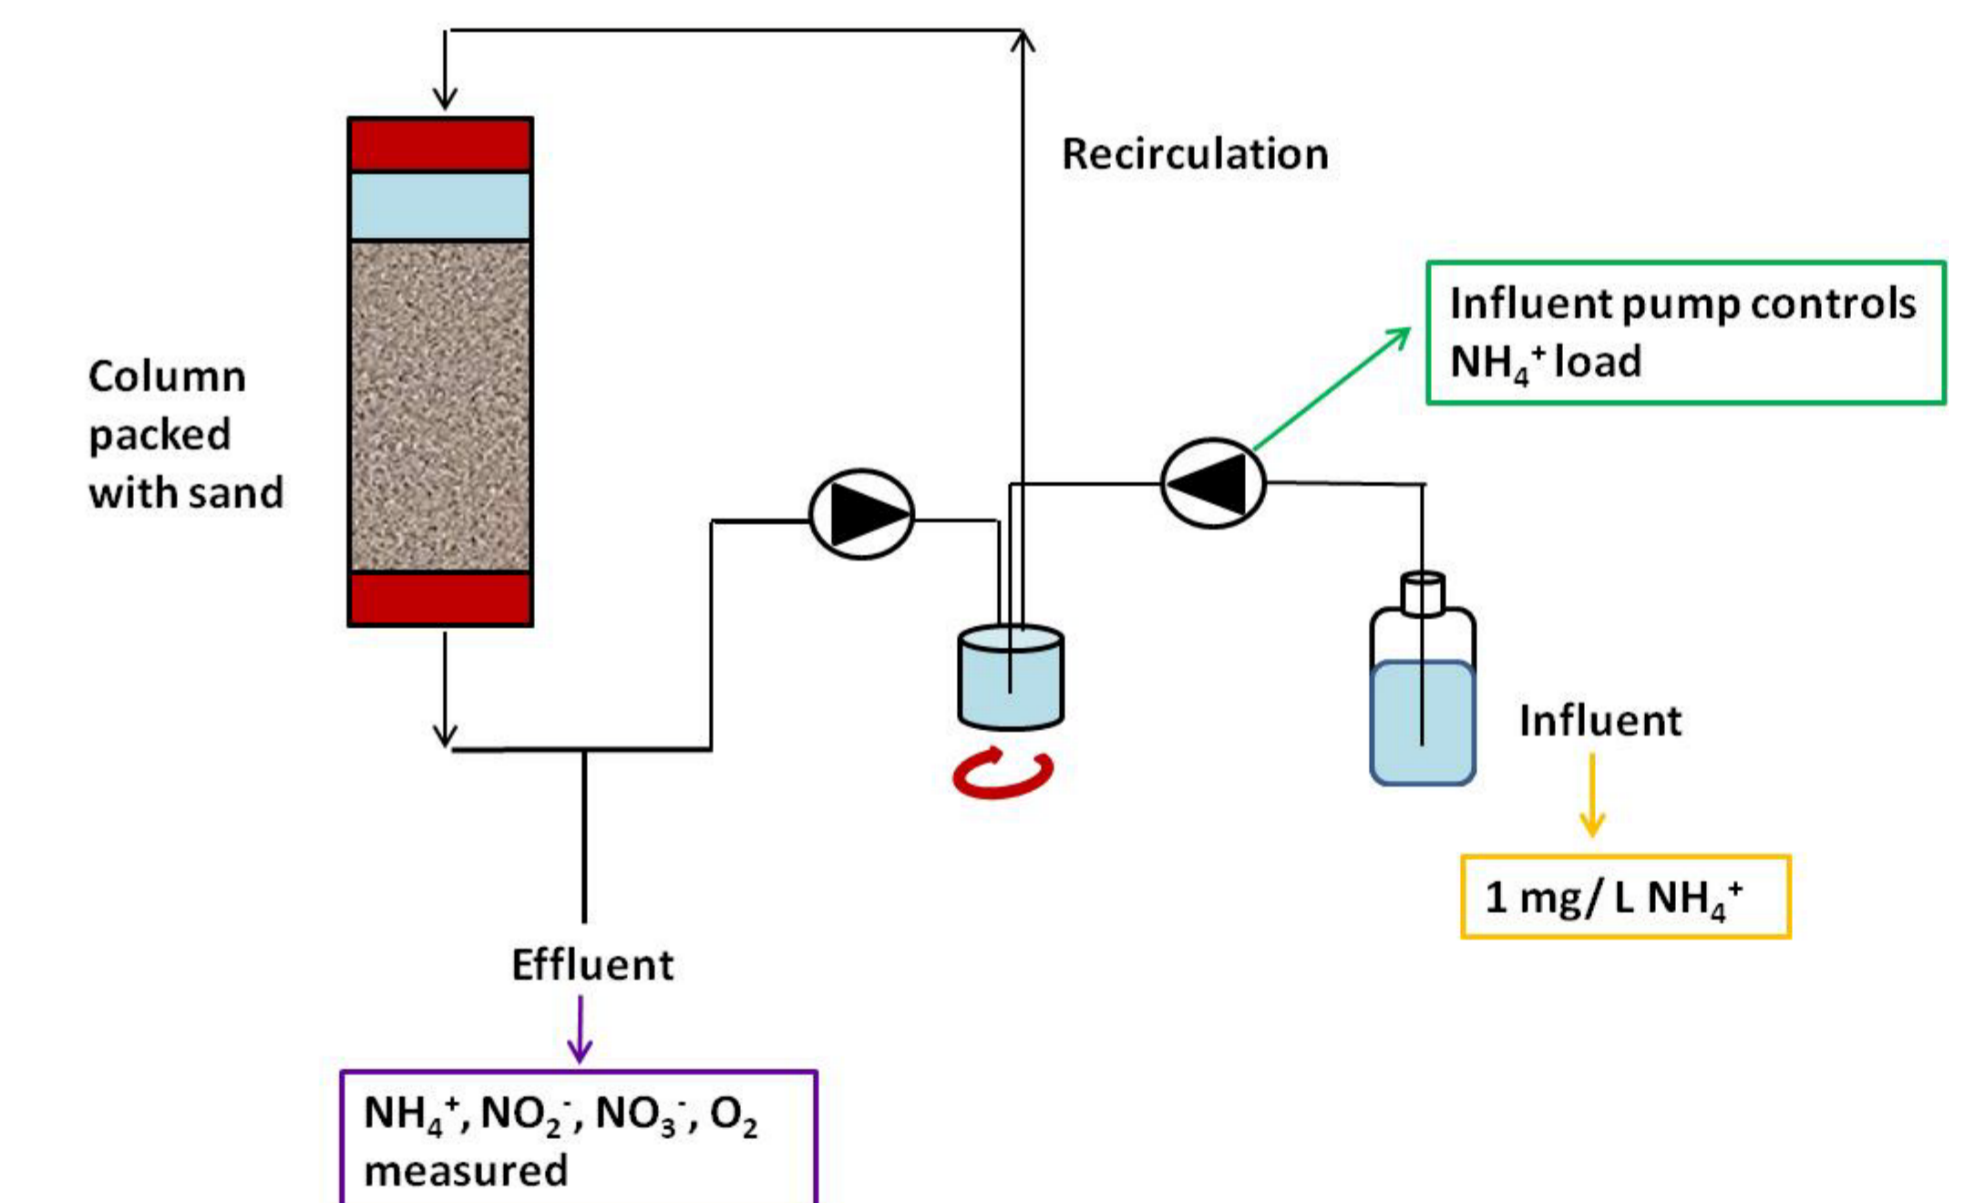

Figure 4: Schematic drawing of experimental set-up. Column dimensions: 5 cm x 2.6 cm  $\phi$ . Loading was controlled by adjusting influent flow rate, influent concentration was 1 mg/L.

## Results

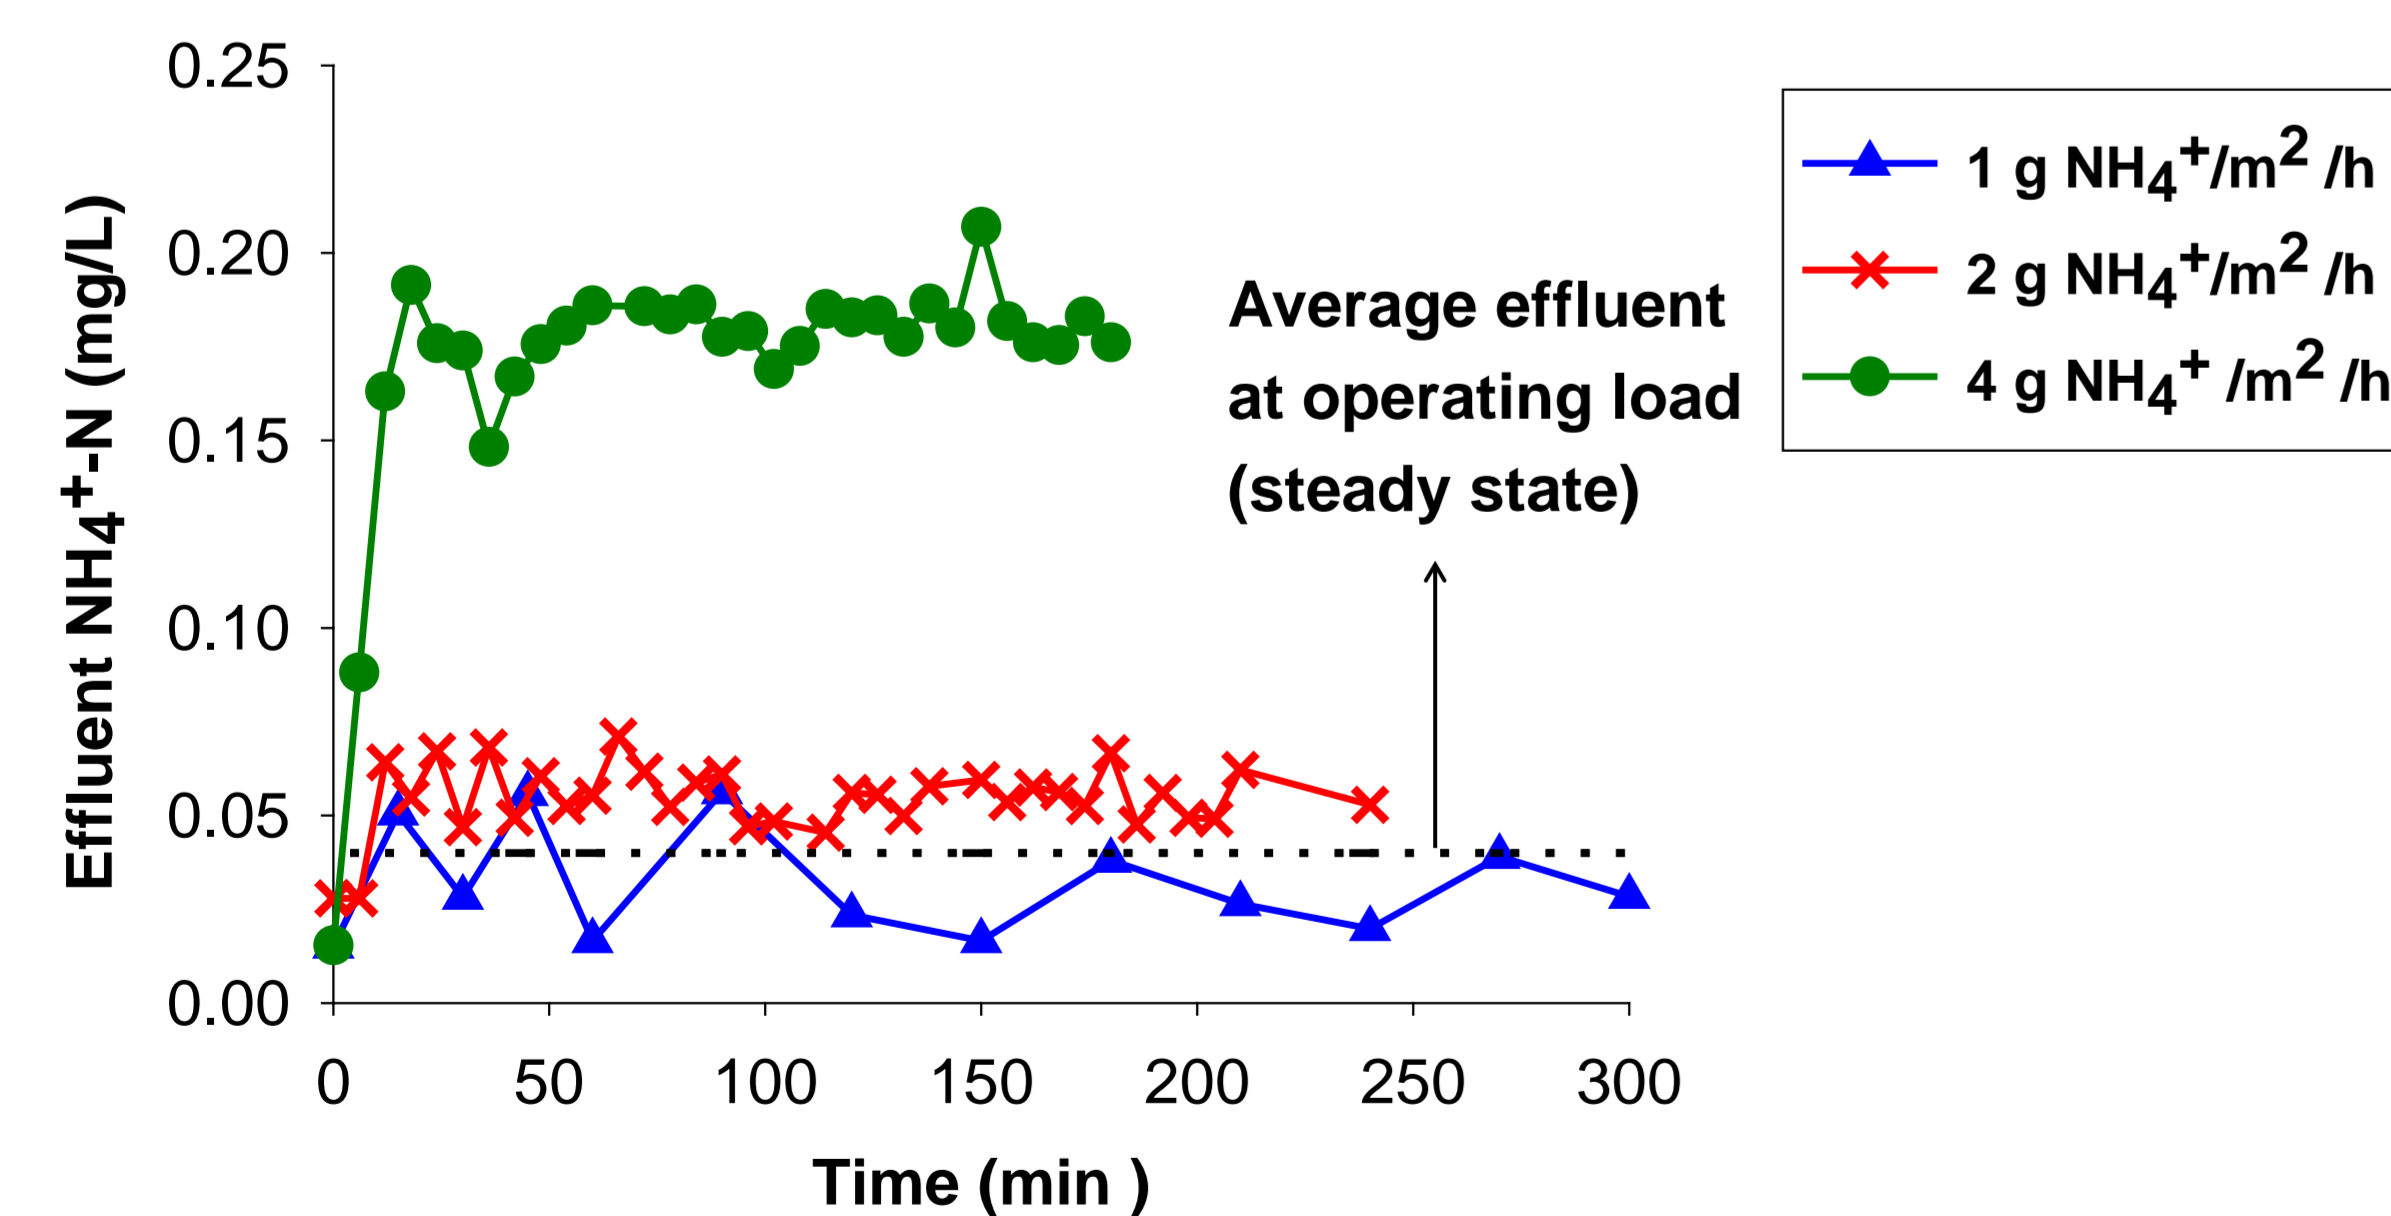

Figure 2:  $\text{NH}_4^+$  effluent concentration profile during loading increase experiments. During each loading change ammonium effluent concentration stabilizes to a new value (temporary steady state)

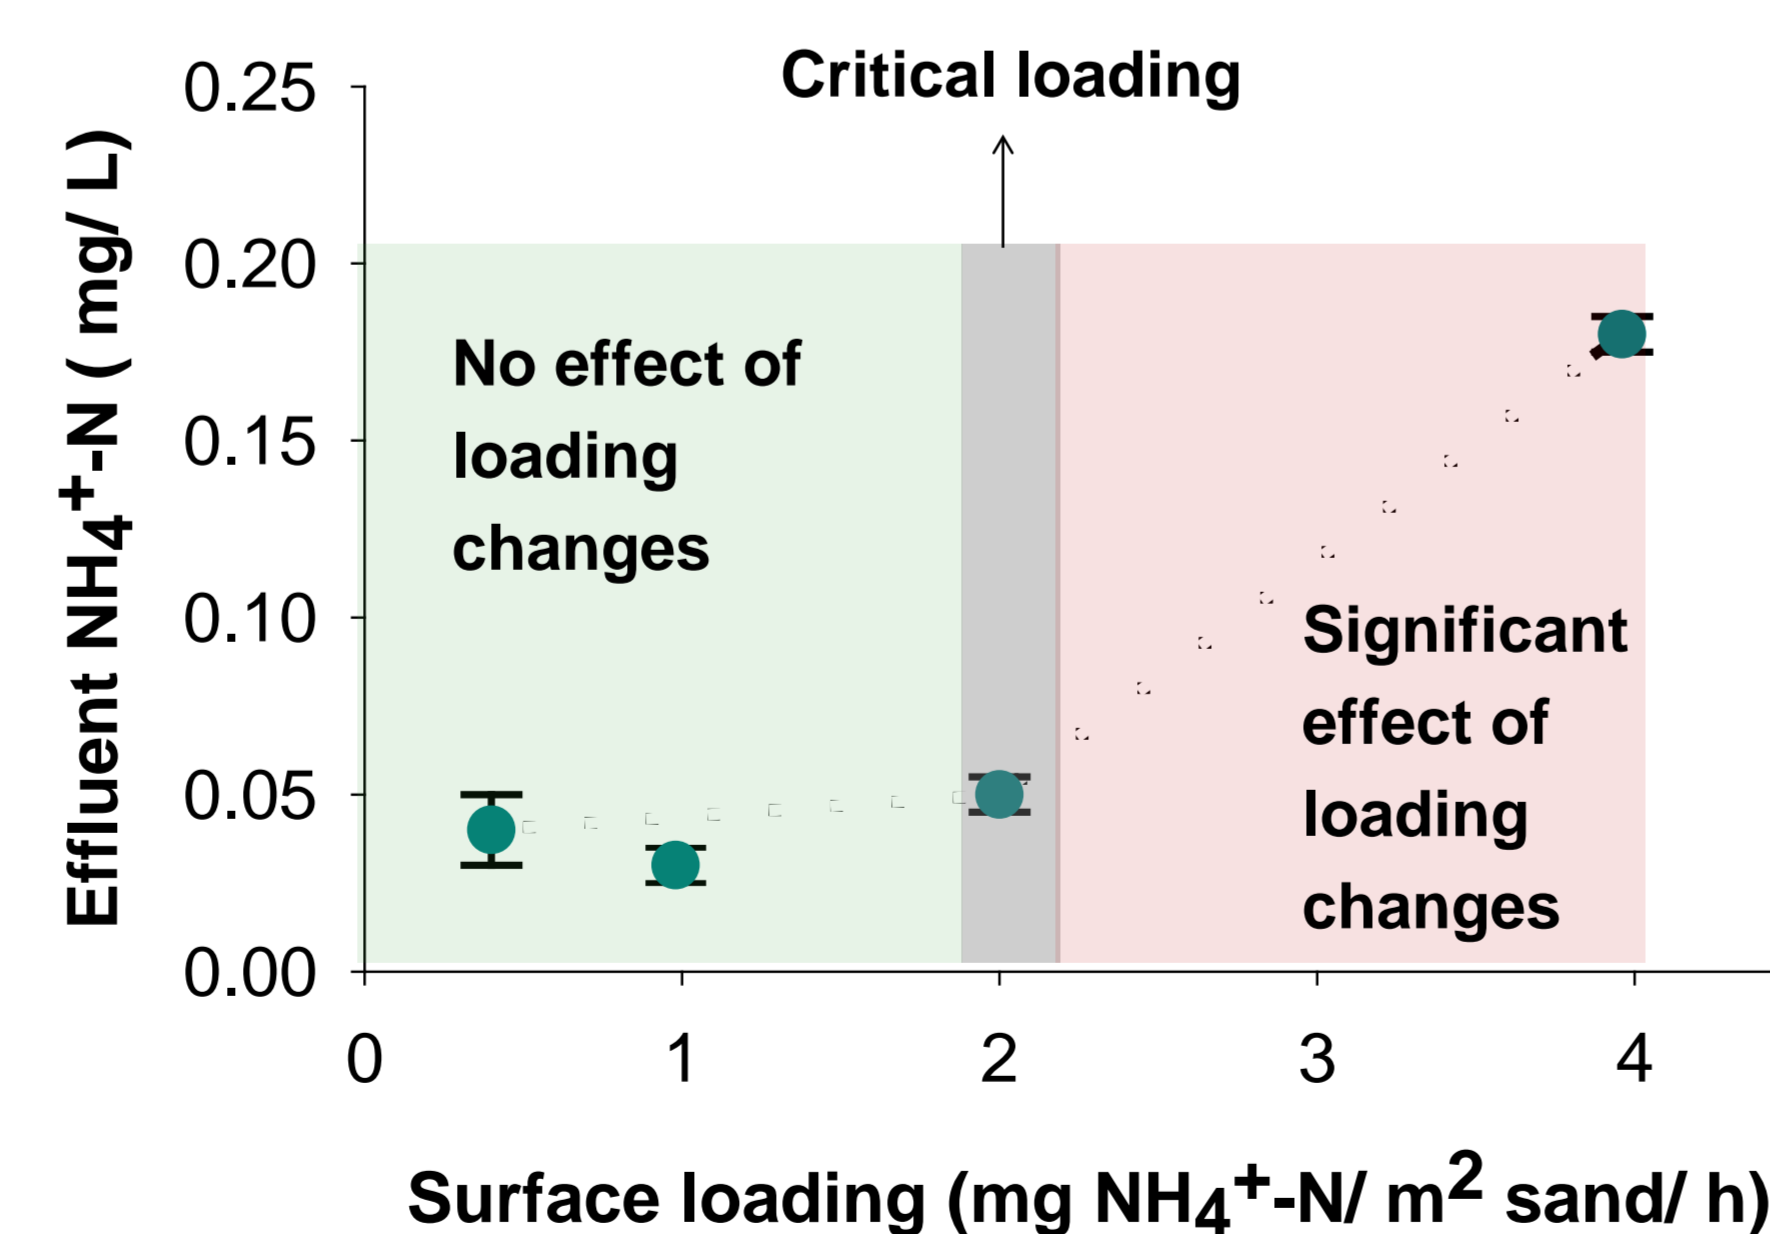

Figure 3: Relationship between  $\text{NH}_4^+$  effluent concentration (temporary steady state concentration) and surface loading

- Loadings up to 2  $\text{mg NH}_4^+ \text{-N/ m}^2 \text{/ h}$  have no effect on ammonium effluent concentration (t-test,  $\alpha = 0.05$ )
- Loadings higher than 2  $\text{mg NH}_4^+ \text{-N/ m}^2 \text{/ h}$  result in higher effluent  $\text{NH}_4^+$  concentration
- **Critical loading = 2  $\text{mg NH}_4^+ \text{-N/ m}^2 \text{/ h}$**

Table 1: Different experimental loads applied. Steady state loading = surface loading of the full scale filter. Duration of experiments was short to avoid growth of nitrifying biomass

Loading (mg $\text{NH}_4^+ \text{-N/ m}^2 \text{ sand surface area / h}$ )	Duration of experiment (h)
0.4	steady state
1	5
2	4
