Manuscript Region of Origin: BRAZIL

Abstract: Allergic diseases are on the rise globally, in parallel with a decline in parasitic infection. The inverse association between parasitic infections and allergy at an ecological level suggests a causal association. Studies in humans have generated a large knowledge base on the complexity of the inter-relationship between parasitic infection and allergy. There is evidence for causal links, but the data from animal models are the most compelling: despite the strong Type 2 immune responses they induce, helminth infections can suppress allergy through regulatory pathways. Conversely, many helminths may cause allergic-type inflammation including symptoms of "classical" allergic disease. From an evolutionary perspective, individuals with an effective immune response against helminths may be more susceptible to allergy. This narrative review aims to inform readers on the most relevant up to date evidences on the relationship between parasites and allergy. Experiments in animal models have demonstrated the potential benefits of helminth infection or administration of helminth-derived molecules on chronic inflammatory diseases, but clinical trials in humans have not so far demonstrated unequivocal clinical benefits. Nevertheless, there is sufficiently strong evidence to support the continued investigation of the potential benefits of helminth-derived therapies for the prevention or treatment of allergic and other inflammatory diseases.

Journal of Allergy and Clinical Immunology Manuscript Review

In order to be eligible to receive CME credit for your review, you must read the following information.

Educational Learning Objectives

1. To update knowledge of the current literature through literature searches conducted for critique of manuscripts
2. To glean new information and understanding of specific areas of study that can impact the reviewers' research or practice
3. To exercise and expand use of critical analytical skills
4. To develop teaching skills by advising authors on study design, scientific method and analysis, and scientific writing
5. To contribute to expansion of the body of knowledge in allergy/ immunology

Accreditation Statement

This activity has been planned and implemented in accordance with the Essential Areas and Policies of the Accreditation Council for Continuing Medical Education (ACCME) by the American Academy of Allergy, Asthma and Immunology (AAAAI). The AAAAI is accredited by the ACCME to provide continuing medical education for physicians.

Designation Statement

The American Academy of Allergy, Asthma and Immunology designates this educational activity for 3.0 *AMA PRA Category 1 Credits*[™] per review, with a maximum of 15.0 credits per calendar year. Physicians should only claim credit commensurate with the extent of their participation in the activity.

Target Audience

This activity is intended for board-certified physicians and researchers in the fields of allergy and immunology.

Overall Purpose/Goal

The purpose of this activity is to affirm or modify knowledge, competence, or performance as a result of reading the manuscript.

DESIGN COMMITTEE:

Cezmi Akdis, MD FAAAAI (Co-Editor-in-Chief): **Employer:** Swiss Institute of Allergy and Asthma Research B) University of Zurich, Switzerland Title: A) Director (SIAF) B) Medical Faculty (University of Zurich) **Competing Relationships:** Advisory Board: Circassia (United Kingdom), Allergopharma (Germany), Novartis (Basel, Switzerland), Teva (Amsterdam, the Netherlands), Anergis (Lausanne, Switzerland); Shareholder (Ongoing): Alimentary Health Pharma (Davos, Switzerland); Shareholder (Ongoing): Davos Diagnostics (Davos, Switzerland) **Organizational Interests:** CK-CARE Christine Kühne - Center for Allergy Research and Education (Ongoing): Directorium Member; GA2LEN, Global Allergy And Asthma European

Network (Ongoing): Ex-com Member World Immune Regulation Meetings (Ongoing): Chair, Organizer.

Andrea Apter, MD MA MSc FAAAAI: Employer: University of Pennsylvania (Professor of Medicine) **Competing Relationships:** NHLBI: RC1 (funded-now complete) - PI, NHLBI (Ongoing): R18, PCORI (Ongoing): PI. **Organizational Interests:** American College of Asthma Allergy & Immunology (Ongoing): Fellow, American College of Physicians (Ongoing): Fellow, American Thoracic Society (Ongoing): Behavioral Science Assembly program committee, Associate Editor (Ongoing): Journal of Allergy & Clinical Immunology, Consultant (Ongoing): UPTODATE. **Conflict Resolution:** The research grant from Bristol-Myers Squibb and AstraZeneca is paid directly to my institution, and 2.5% of my salary is supported by these grant funds. The research focuses on a diabetes drug, and is not related to any of their respiratory products.

Leonard Bacharier, MD FAAAAI: Employer: Washington University (Professor of Pediatrics) **Competing Relationships:** AstraZeneca China (Ongoing): Honoraria for lectures, DBV Technologies (Ongoing): Consultant, Novartis (Ongoing): Honoraria for lectures, Teva (Ongoing): Honoraria for lectures, consultant, Sanofi (Ongoing): Advisory Board attendance, NIH/NHLBI/NIAID (Ongoing): Investigator: AsthmaNet, Severe Asthma Research Program, Inner City Asthma Consortium. **Organizational Interests:** AAAAI (Ongoing): Fellow, Editorial Boards of JACI and JACI: In practice, AMPC Member (Ongoing). **Conflict Resolution:** Will present data from a variety of published peer-reviewed studies.

Claus Bachert, MD PhD: Employer: Universitair Ziekenhuis Gent (Professor, Chief of Clinics) **Competing Relationships:** ALK (Ongoing): speaker, Allergopharma: speaker, board, Bionorica (Ongoing): speaker, board, Genentech: board, Meda (Ongoing): speaker, board, MSD (Ongoing): speaker, Novartis (Ongoing): board, Stallergenes (Ongoing): speaker, Uriach (Ongoing): speaker, board. **Organizational Interests:** DGAKI (Ongoing): Vice President, WAO (Ongoing): Executive Board. **Conflict Resolution:** Spread of bias over many companies, no direct influence in any presentations.

Zuhair K. Ballas, MD FAAAAI: Employer: University of Iowa Health Care (Professor of Medicine) **Competing Relationships:** Honorarium/Gift: Up-To-Date, Immune Deficiency Foundation, NIH (Ongoing): Received grant, Veterans Administration (Ongoing): Received Merit grant. **Organizational Interests:** Clinical Immunology Society (Ongoing): Member of Nominating committee, Immune Deficiency Foundation (Ongoing): immunodeficiency consultant, Medical Advisory Council.

Joshua A. Boyce, MD FAAAAI: Employer: Brigham and Women's Hospital (Albert L. Sheffer Prof of Medicine; Director, Inflammation and Allergic Disease Research Section) **Organizational Interests:** Consultant: Calcimedica, LPath, Inc. (Ongoing).

Robert K. Bush, MD FAAAAI: Employer: Retired; **Competing Relationships:** Honorarium/Gift: Section editor Current Opinion in Allergy&Clinical Immunology and Current Allergy Reports, Honorarium/Gift: Section editor Allergy & Immunology Reports

Javier Chinen, MD PhD FAAAAI: Employer: Baylor College of Medicine (Associate Professor) **Nothing to disclose.**

Raif S. Geha, MD FAAAAI: Employer: Children's Hospital of Boston (Chief, Div. Imm., Prof. Ped.) **Nothing to disclose.**

Kenji Kabashima, MD PhD: Employer: Kyoto University (Professor) **Competing Relationships:** A*Star (Senior Principal Investigator) **Competing Relationships: Advisory Board:** Chugai, Janssen, Ono Pharmaceutical (Ongoing), Daiichi Sankyo, Polo Pharma, Kao Co.

Carole Ober, PhD: Employer: University of Chicago (Professor) **Nothing to disclose.**

David B. Peden, MD MS FAAAAI: Employer: University NC School Medicine (Andrews Distinguished Professor of Pediatrics, Medicine and Microbiology/Immunology) **Nothing to disclose.**

Harald E. Renz, MD FAAAAI: Employer: Philipps University Marburg (Professor and Director) **Organizational Interests:** Deutsche Gesellschaft für Klinische Chemie und Laboratoriumsmedizin (DGKL) (Ongoing): Chairman Working Group Autoimmune Diagnostics Deutsche Gesellschaft für Allergologie und Klinische Immunologie (DGAKI) (Ongoing): President.

Marc E. Rothenberg, MD PhD FAAAAI: Employer: Cincinnati Children's Hospital Medical Center (Director of the Division of Allergy and Immunology) **Competing Relationships:** Consultant: Novartis, NKT Therapeutics, Celsus Pharmaceuticals (Ongoing), Immune Pharmaceuticals (Ongoing), Receptos. **Organizational Interests:** American Partnership for Eosinophilic Disorders (Ongoing): Member, Medical Advisory Board CEGIR (Consortium of Eosinophilic Gastrointestinal Disease Researchers) (Ongoing): Principal Investigator, International Eosinophil Society (Ongoing): Steering Committee TIGERS (Ongoing): Steering Committee. **Conflict Resolution:** I present unbiased information in my activities for the AAAAI, and I am not currently studying any product produced by these companies.

Hirohisa Saito, MD PhD FAAAAI: Employer: National Research Institute for Child Health & Development (Deputy Director of the Research Institute) **Competing Relationships:** Speaker: Teijin Pharma Ltd, Shiseido Co.,Ltd., MSD (Merck Sharp and Dohme) K.K., Ono Pharmaceutical Co., Ltd., GlaxoSmithKline K.K., Pfizer Japan Inc., Kyowa Hakko Kirin, Kyorin Pharmaceutical, Daiichi Sankyo.

Stanley Szefler, MD FAAAAI: Employer: University of Colorado Denver School of Medicine (Professor of Pediatrics; Head, Pediatric Asthma Research) **Competing Relationships:** Advisory Board: Aerocrine, Boehringer-Ingelheim, Novartis, Roche, Glaxo Smith Kline. NIH:NHLBI (Ongoing): Research Grant: AsthmaNet, NIH:NIEHS/EPA (Ongoing): Research Grant: Childhood Health and Environmental Center Grant, Colorado Public Health Department (Ongoing): Research Grant, NIH:NIAID (Ongoing): Research Grant: Inner City Asthma Consortium. **Organizational Interests:** AAAAI (Ongoing): Fellow; Deputy Editor For Journal

of Allergy and Clinical Immunology, ACAAI (Ongoing): Fellow, American Academy of Pediatrics (Ongoing): Fellow, American Thoracic Society (Ongoing): Member, Colorado Allergy and Asthma Society (Ongoing): Member. **Conflict Resolution:** I disclose my potential conflicts at all meetings and lectures. I focus my working relationships on research and providing advice on drug development, as well as overseeing research studies. I do not provide lectures that serve as marketing formats for specific drugs. I also disclose all of my financial relationships to University of Colorado for ongoing review.

Stephan Weidinger, MD, PhD

Employer: Christian-Albrechts-University of Kiel and University Hospital Schleswig-Holstein.

Competing Relationships: Speaker: Sanofi-Aventis, Novartis, Galderma. Advisory Boards: Astellas, Novartis, Sanofi-Aventis. Research Grants: Sanofi-Aventis (ongoing), La Roche Posay (ongoing), Novartis (finished), Pfizer (finished), Biogen (finished).

Organizational Interests: EAACI (secretary dermatology section); Associate Editor for Journal of Investigative Dermatology, Allergy

Robert A. Wood, MD FAAAAI: Employer: Johns Hopkins University School Medicine (Professor of Pediatrics) **Competing Relationships:** Research Grants: NIAID (Ongoing), DBV Technologies (Ongoing), Aimmune (Ongoing), Astellas (Ongoing) Up To Date (Ongoing): Royalties.

56 **Abbreviations:**

57 AcK1 - a large family of ShK-related peptides

58 AAMΦs - alternatively activated macrophages

59 BmK1 - a large family of ShK-related peptides

60 CAMΦs - classically activated macrophages

61 CD11c_{high} DC – conventional dendritic cells

62 CD4⁺ T cells – T Helper Lymphocytes

63 CD4⁺ CD25⁺ FOXP3⁺ - regulatory T cells

64 CTLA-4 - inhibitory molecule cytotoxic T lymphocyte- associated antigen 4

65 DC – dendritic cells

66 ES - excretory-secretory molecules of helminths

67 FEV₁ - Forced expiratory volume in 1 second

68 HIC – high income countries

69 iNOS – inducible nitric oxide synthase

70 LMIC – low- and middle-income countries

71 IL – interleukin

72 ILC – Innate lymphoid cells

73 IL2R – interleukin 2 receptor

74 IFN γ – interferon gama

75 LD - linkage disequilibrium

76 PBMC – peripheral blood mononuclear cells

77 PG – prostaglandin

78 SPT – skin prick test

79 STH – soil transmitted helminths

80 SWAP – *Schistosoma* soluble adult worm antigen

81 ST2 – IL33 receptor

82 sST2 – a soluble form of ST2

83 sIgE – specific IgE

84 tIgE – total IgE

85 Th – T helper cells

86 TLR –toll like receptors

87 TGFB - Transforming growth factor beta

88 TSLP - Thymic stromal lymphopietin

- 89 Type 2 immune response – pattern of immune response including the Th2 cells (CD4+ cells),
90 ILC2s and other to the cytokine milieu formerly related exclusively to Th2 activation

113

114 **Introduction**

115 The frequency of allergic disease has been rising in urban and urbanizing populations,¹ while
116 an overall decline in rates of infections has been observed. Studies of the inverse association
117 between parasitic infections and allergy suggest the existence of a causal link.

118 While humans can be infected with some 300 species of worms and over 70 species
119 of protozoa² we will focus on soil-transmitted helminths (STH). Worldwide, it is estimated
120 1.5 billion humans are infected with one of these species.³ We will also refer to *Schistosoma*
121 *spp.* that infect humans through contact of skin with water infested with larvae and it is
122 estimated to infect 230 million people.⁴

123 For example, Figure 1 shows typical features of a rural household in a village of
124 Conde, Northeast Brazil, from 2005, in which the prevalence of helminth infections was
125 83.5%.⁵ In the City of Salvador, 185 km away, the frequency of helminth infection among
126 children was below 20%.⁶ An ecological study including all Brazilian municipalities reported
127 hospitalization rates due to asthma were lower in those endemic for *S. mansoni* or for STH
128 parasites.⁷ A typical urban underserved neighborhood of Salvador, is presented in Figure 2.

135

136 The purpose of this narrative review is to inform clinicians and researchers on the
137 most current evidence on this topic, from epidemiological studies to mechanisms and
138 molecules identified in helminths that are candidates for novel therapeutics.

139

140 **Global trends in parasite infections and allergy**

141

142 *Global trends*

143 Allergic diseases are among the most common chronic diseases¹ particularly in populations
144 undergoing urbanization.⁸ Individual risk of allergy is considered to reflect a complex
145 interaction between genetic predisposition and environmental exposures over the life course.⁹
146 Geographic differences in the prevalence of allergy between and within populations is more
147 likely to reflect exposures to common environmental factors that may either increase or
148 decrease risk. The most consistent environmental exposures considered to reduce risk of
149 allergy are those associated with rural residence and include farming, animal exposures¹⁰ and
150 infections with parasites.¹¹

151 Protective immunity against STHs is mediated through type 2 immune mechanisms¹¹
152 and parasites can survive to cause chronic infections by modulating these allergic
153 inflammatory responses. The prevalence of STH infections is declining worldwide. This
154 reflects a combination of factors leading to reductions in transmission of these infections,
155 including reductions in extreme poverty and improvements in the living environment (potable
156 water and disposal of feces) and the wide availability of anthelmintic drugs. Reductions in

157 STH prevalence, while beneficial, might raise concerns in case of being causally associated
158 with allergy.

159

160 *Epidemiological evidence for associations between parasites and allergy*

161 There is evidence in support of protection against allergy by STH infections, but many
162 studies in human populations present discordant effects.

163 Meta-analyses of observational studies have shown differences in effects on asthma
164 symptoms for different parasites: while *A. lumbricoides* was associated with an increased risk
165 of asthma, hookworm infection was associated with a reduced risk.¹² In contrast, studies that
166 have measured the presence of *Ascaris*-specific IgE - recommended by some as a marker of
167 infection in areas of low prevalence¹³ but perhaps more appropriately used as a marker of
168 allergic sensitization to *Ascaris* - have shown consistently positive associations with asthma
169 symptoms and even disease severity.^{14,15}

170 In the case of atopy, generally measured by allergen SPT reactivity, most cross-
171 sectional studies have shown inverse associations with STH infections.¹⁶ A meta-analysis of
172 cross-sectional studies showed that current STH infections were protective against atopy, an
173 effect that was consistent for all 3 of the most common STH infections and also
174 schistosomiasis.¹⁶ STH infections are not alone in their SPT attenuating effects. A cross-
175 sectional study showed that, in addition to *A. lumbricoides*, several different childhood
176 infections were independently and inversely associated with SPT, including visceral worm
177 *Toxoplasma gondii*, *Herpes simplex* and Epstein-Barr virus infections.⁶ This observation
178 raises the possibility that rather than mediating protection directly, STH infections might be
179 markers of poor environmental conditions that mediate protection through alternative

180 mechanisms. Interestingly, in the study mentioned above, *T. gondii* was the only organism
181 associated with a reduction in allergen-specific IgE in this population.⁶

182 Few prospective studies have explored the effects of geohelminths on the
183 development of allergy. It has been suggested that the key effects of protective environmental
184 exposures, occur during early life during which there may be a limited window of
185 opportunity for such exposures to mediate their effects.⁹ If this is the case, prospective studies
186 of the effects of STH infections on allergy should start in early childhood, ideally before birth
187 to measure any potential *in utero* effects of maternal STH infections. Four such prospective
188 studies have been published to date; i) a birth cohort in Ethiopia where the prevalence of
189 helminthiasis was considered to be too low to explore effects on wheeze and eczema to 5
190 years;¹⁷ ii) an observational analysis within a randomized-controlled trial of anthelmintic
191 treatment during pregnancy showed that maternal and childhood hookworm and childhood *T.*
192 *trichiura* were associated with a reduced risk of eczema to 5 years;¹⁸ iii) a prospective study
193 showed that *T. trichiura* infections during the first 5 years of life were associated with a
194 reduced risk of SPT in later childhood;¹⁹ and iv) a birth cohort in a rural area did not show an
195 effect of maternal STH infections on SPT, wheeze, or eczema during the first 3 years of
196 life,²⁰ but follow-up of the cohort is in progress to determine if childhood infections may
197 affect risk of allergy at school age.²¹

198 Another way used to test the causal link has been the interventional studies in which
199 the protective exposure (i.e. STH) is removed through anthelmintic treatment thus intended to
200 reverse any existing effects. If helminths are truly protective, one might expect to observe an
201 increase in the prevalence of allergy in the group receiving treatment. Several intervention
202 studies have inconsistent findings.^{22,23,24} None of the studies were able to show an effect on
203 the prevalence of asthma symptoms, one showed that a single dose of anthelmintic drugs
204 given during the latter part of pregnancy was associated with an increased risk of eczema in

205 infancy,²² and two showed an increase in either the incidence²³ or frequency²⁴ of positive
206 SPT after at least 1 year of treatments.

207 Overall, the evidence suggests that *A. lumbricoides* infection and particularly *Ascaris*-
208 specific IgE is associated with an increased risk of asthma symptoms in endemic areas but
209 that STH infections may reduce the prevalence of positive SPT, but not specific IgE (sIgE) to
210 aeroallergens. There is still very limited evidence that STH infections protect against allergic
211 symptoms in human populations, and the effects of early life exposures to STH infections on
212 the development of allergy in childhood, either through maternal or childhood infections, is
213 still insufficiently studied.

214 In case of schistosomiasis, all published studies have been cross-sectional showing an
215 inverse association between *Schistosoma mansoni* infection and SPT reactivity to common
216 aeroallergens in most cases¹⁶. A recent study in Uganda was unable to demonstrate an
217 association between *S. mansoni* infection and wheeze but an earlier study in Brazil showed
218 that *S. mansoni* infection was associated with a milder form of asthma.²⁵

219

220 **Host immune response against parasites**

221 Helminths are the largest organisms to infect vertebrate hosts, leading to the release of large
222 quantities of parasite molecules that interact with the immune system. It might be expected
223 that helminth infections should induce an overwhelming immune response, resulting in the
224 elimination of the parasites, while causing potentially damaging inflammation. However, co-
225 evolution of hosts and parasites over millennia has allowed both host and parasite to survive
226 through the development of mechanisms that dampen the host inflammatory response to the
227 parasite or even allow the parasite to evade the host immune response, resulting in infections

228 that are often asymptomatic.¹¹ For example, *Schistosoma spp* adults, that live within the
229 human vascular system, can survive for many years without inducing strong host
230 inflammatory responses.²⁶

231 Although the most widely studied host immune response against helminths is the
232 acquired Th2-type response, we shall discuss both innate and adaptive host immune
233 responses to helminth parasites. The Th2 type response is characterized by the production of
234 high levels of the cytokines IL4, IL5, IL9, IL10, IL13, IL21, IL33. These cytokines
235 orchestrate immediate hypersensitivity that involves B cell class switching to IgG4 and IgE,
236 eosinophilia, goblet cell hyperplasia and mastocytosis, alternative activation of macrophages,
237 and the influx of inflammatory cells such as eosinophils that contribute to parasite killing.
238 Such a response may control parasite numbers by killing them in tissues or expelling them
239 from the intestinal lumen.[≈] The host response to helminth infections is associated with
240 allergic phenomena that are a consequence of killing or an attempt to kill or expel these
241 parasites.²⁷ Examples are shown in Table 1.

242 Although helminth parasites are universal in inducing all or most of these Th2
243 effector pathways in the host, the specific effector pathway mediating protection varies
244 between different parasites, life cycle stages, and site of infestation. For example, the
245 intestinal helminths, *Heligmosomoides polygyrus* and *Trichinella spiralis*, are expelled from
246 the intestinal lumen by several Th2 effector pathways such as IgE-mediated activation of
247 mucosal mast cells. Th1 responses may also have a role in protective immunity against some
248 helminth parasites such as *S. mansoni* infection,²⁸ while the control of parasite burden in
249 strongyloidiasis is highly dependent on type 2 responses.²⁹

250 The parasite's first contact with the host's immune system is through CD11c_{high} DC
251 which undergo alternative activation for example, in response to excretory-secretory (ES)

252 molecules from the murine intestinal helminth parasites *Heligmosomoides polygyrus* and
253 *Nippostrongylus brasiliensis*.³⁰ Helminth molecules bind to TLR2, 3, 4 receptors on the
254 dendritic cell membrane driving the acquired immune response from naive Th0 to a Th2
255 profile.³¹

256 An important group of innate immunity cells, the innate lymphocyte (ILCs), which
257 lack B or T cells antigen specific receptors, and do not express myeloid or dendritic cell
258 markers, has been shown to comprise three sub-sets: ILC1 (related to T1 profile), ILC2
259 (related to T2) and ILC3 (related to Th17).³² ILC2 produce a large set of T2 cytokines (IL4,
260 IL5, IL9, IL13 and IL21) in response to stimulation with IL25, IL33 and TSLP³² and play an
261 important role in protection against helminths. However, unlike Th2 cells, ILC2 are
262 stimulated by alternatively activated macrophages (AAMΦs), express MHC-II, and are able
263 to endocytose and process antigen.³³ AAMΦs are phenotypically distinct from classically
264 activated macrophages (CAMΦs) that are typical of Th1 type responses. AAMΦs do not
265 produce IFN γ and instead of inducible nitric oxide synthase (iNOS), have upregulated
266 expression of Arginase-1 that has higher affinity for arginine, competing with iNOS present
267 in CAMΦs. AAMΦs are induced during infections with several helminth parasites.³⁴
268 Interestingly, an interaction between ILC2 and Th2 cells for maintaining AAMΦs in lungs of
269 hookworm-infected mice has been reported.³⁵

270 Other immune cells reported to play a role in immunity against helminth infection are
271 the Th17, derived from CD4(+) T cells after antigen maturation. Th17 cells are important for
272 the clearance of several extracellular pathogens, such as bacteria and helminths.³⁶ In *S.*
273 *japonicum*-infected mice, there was an increase in Th17 cells following granuloma
274 development, attributed to the presence of induced factors (e.g. TGFB, IL23 and IL21) in
275 greater amounts than inhibitory factors (e.g. T_{reg} and T2 cells, and IL-4).³⁷

276 Helminths have developed several mechanisms to suppress or avoid host anti-parasite
277 responses. For example, *S. mansoni* has developed parasite stage-specific evasion strategies.
278 Entry of cercariae through the skin is followed by the release of larval ES products (e.g.
279 PGD2) that cause host cells to release PGE2.³⁸ Both host and parasite-derived prostaglandins
280 induce the production of *IL10* in the skin that inhibits the migration of epidermal Langerhans
281 cells to the invasion site.³⁹

282 The most remarkable evasion strategy used by helminths, particularly those dwelling
283 within host tissues and in blood and lymphatic systems, is the down-modulation of the host
284 immune system leading to a form of immunologic tolerance that, itself, may have effects on
285 host responses to other infections and allergy. The cells mediating this effect are the T_{reg} sub-
286 set of the CD4+ T lymphocytes that produce the immune modulatory cytokines IL10 and
287 TGFβ. The presence of regulatory cells is associated with a reduction in Th2 cells and the
288 development of a modified type 2 immune response. Other cells involved are alternatively
289 activated macrophages and B-regulatory cells.¹¹

290

291

292

Schematic representation summarizing the findings from epidemiological studies of the
relationships between helminth parasites and atopy and asthma

293

294

295 **Commonalities between the immune response to parasites and allergy**

296 The host immune response to helminth parasites has many features in common with allergy.
297 Bronchial inflammation of atopic asthma is coordinated by cells of the adaptive immune
298 system, but also by ILC2 of the innate response, which together induce a type 2 response.⁴⁰

299 During helminth infections type 2 immunity is initiated at the site of parasite invasion by
300 epithelial cells, which release the alarmins IL25 and IL33 to prompt ILCs to produce IL13
301 and other cytokines that are also involved in the pathoetiology of asthma. In the absence of
302 either IL25 or IL33, resistance to helminth infections is severely impaired.⁴¹ T_{regs} cells have a
303 dual role in helminth infections: they protect the host from excessive inflammatory responses
304 during infection, but they also may decrease protective immunity and, thereby, permit
305 parasite persistence.⁴² In the case of asthma, several studies have shown allergic patients to
306 have lower numbers of T_{regs} in both the bronchoalveolar lavage and peripheral blood
307 monocytes cells (PBMC).⁴³ Thus, there are notable parallels between the immune responses
308 associated with allergy and those observed in response to helminth infection.

309 Host type 2 immune responses to parasites and allergens are induced by a limited
310 number of protein families that contain allergens such as tropomyosins. There is extensive
311 structural homology between allergens from helminths and other environmental sources.⁴⁴
312 Further, allergen homologues derived from parasites and aeroallergens do not just exhibit IgE
313 cross-reactivity but can also induce cross-sensitization in murine models.⁴⁵ Cross-reactivity
314 between helminths and aerollergens has a number of important consequences including false-
315 positive reactions for specific IgE when used in the diagnosis of allergy and also a potential
316 increase in morbidity caused by inflammatory reactions directed against cross-reactive
317 allergens. In the case of the latter, cross-reactivity could help drive the exaggerated responses
318 associated with inflammatory syndromes that have been reported in human helminth
319 infections such as tropical pulmonary eosinophilia in the case of lymphatic filariasis⁴⁶ and
320 Loeffler's syndrome in ascariasis.⁴⁷ Likewise, it has been suggested that immune modulation
321 during chronic helminth infections, which subvert Th2-mediated inflammation permitting
322 parasite survival, could affect atopic responses to common aeroallergens through either
323 bystander effects or immunological cross-reactivity.⁴⁵

324

325

Insert Figure 4.

326

Helminths suppress autoimmunity and allergy via type 2 or regulatory immune response.⁴⁸

327

328

Genetic determinants of protection against helminths and risk of allergy

329

330

Characterization of parasite genomes and subsequent comparison of parasites to more

331

complex species such as mammalian hosts have contributed to our understanding of the

332

mechanisms of parasite evolution and have provided evidence for the role of host–parasite

333

interaction in genetic adaptation. An understanding of that genetic adaptation has elucidated

334

candidate genes, which may drive susceptibility to other diseases of the immune system,

335

including atopy and asthma.⁴⁹ Thus, genetic variants affecting any of the classical key-roles

336

inflammation inducing factors as well as proteins related to controlling inflammation through

337

immune regulatory mechanisms such as T_{reg} may play a role on both helminth resistance and

338

allergic conditions. Genetic studies have highlighted common variants (MAF >10-30%) that

339

affect allergy in many different ways. In Figure 5, an analysis using PANTHER version 11⁵⁰

340

is presented showing different pathways related to the main genes described in GWAS to

341

date, in which one may observe 3 out of the top 4 pathways linked to asthma are related to

342

interleukin signaling and inflammation.

343

The genetic variants that affect protection against helminths and risk of allergy, can

344

be organized in two main groups: those affecting Th2 immune response and those affecting

345

regulatory mechanisms.

346

347

Insert Figure 5:

348

Pathway analysis using Panther 11 version for the top SNPs associated in GWAS for

349

asthma to date.

350

351

352 *Variants that affect Th2 immune response*

353

354 Common genetic variants of type 2 immune signaling relating to allergy and asthma provide

355 credence to the hypothesis that the origin of these allergy-promoting variants derives from

356 evolutionary mechanisms and their selection occurred in the presence of widespread,

357 endemic helminth infection.⁵¹ A region on chromosome 5, 5q31-q33, for example, has been

358 associated with resistance to *S. mansoni* through the presence of genes such as those of

359 granulocyte-macrophage factor (*CSF2*), *IL3*, *IL4*, *IL5* and *IL13*, that are important in

360 protective immunity against *S. mansoni*.⁵² The same locus (5q31-q33) has been linked to

361 asthma and atopy. Other relevant loci that are also linked to asthma are 7q and 21q.⁵³

362 In terms of asthma susceptibility, several immune molecules have been associated

363 with asthma/allergy. In both GWAS and candidate genes studies some 200 genes have been

364 associated with asthma or related phenotypes. Among these genes, there are those related to a

365 possible modulation of plasma tIgE levels.⁵⁴ Association studies of genes encoding the

366 epithelial cell-derived cytokines, *IL33* and *TSLP*, and the *IL1RL1* gene encoding the IL33

367 receptor, ST2, highlight the central roles for innate immune response pathways that promote

368 the activation and differentiation of Th2 cells. These genes are the most consistent variants
369 associated with asthma, allergy and helminth infections across ethnically diverse
370 populations.⁵⁵

371 In this context, GWAS studies for allergic diseases have pinpointed *IL33* and *IL1RL1*
372 as key susceptibility genes for allergic asthma, underscoring the pivotal role of this pathway
373 in the pathophysiology of these diseases.⁵⁶ Studies involving the genes codifying the *IL33/ST2*
374 route have been widely replicated in different populations,⁵⁷ confirming their association with
375 asthma⁵⁸ and blood eosinophilia.⁵⁹ The mechanism whereby the *IL33/ST2* axis induces Th2-
376 inflammation was demonstrated recently.⁶⁰ Local airway soluble ST2 (sST2) levels, as well
377 as circulating plasma sST2 levels, contribute to neutralization of IL33 in the tissues.

378 The role of human genetic determinants of *IL33/ST2* in helminth infection is poorly
379 understood. Using a generalized estimating equation model, three SNPs associated with
380 higher SWAP specific IgE/IgG4 (a measure of resistance to *S. mansoni*) were found.⁶¹ The
381 most significant SNP mapped to intron 1, and the allele, which has been shown to confer
382 asthma risk in an African-American population, also conferred protection against
383 schistosomiasis.

384 Major polymorphisms within the 5q31-q33 genomic region, previously associated
385 with resistance to *S. mansoni* infection have been studied.^{52,53} The region includes several
386 genes related to immune function including IL-4, IL-5, and IL-13 genes in the Th2 cluster.
387 Resistance to *S. haematobium* was associated with the *IL13*-1055T/T genotype⁶² which has
388 also been implicated in asthma exacerbations.⁶³ Further, a functional *IL13* polymorphism,
389 rs1800925T, was shown to contribute to the risk of late-stage schistosomiasis caused by *S.*
390 *japonicum*.⁶⁴ In another study, two quantitative traits, tIgE levels (representing Th2 pathway
391 activation) and *S. mansoni* egg counts, that reflect host immunity to helminths were

392 investigated, providing a unique opportunity for the genetic dissection of the Th2 pathway in
393 the context of schistosomiasis.⁷ Significant associations were seen between two functional
394 variants on the IL13 gene and *S. mansoni* egg counts, indicating IL13 to be protective, but no
395 associations of IL13 gene variants with tIgE levels. Since the functional effect of both
396 variants on the gene product, IL13, is to increase its amount or activity, this finding suggests
397 IL13 functions to increase anti-helminth immunity, and functional variants may be an
398 evolutionary vestige of selective forces that may now favor atopic phenotypes.⁵

399

400 *Variants that affect immune regulatory mechanisms*

401 Alterations in regulatory cytokine levels are believed to play an important role in mediating
402 immune suppression in helminth immune response. Genetic variants affecting *IL10* and
403 *TGFBI* may be associated with both asthma/allergy and heminthiasis. We described a variant
404 (rs3024496, G allele) in the IL-10 gene associated with the suppression of IL-10 production
405 in *A. lumbricoides* antigen-stimulated cultures of peripheral blood leukocytes, and also, other
406 variants within the same gene, were both positively associated with atopy and asthma and
407 negatively associated with helminth co-infections.⁶⁵

408 Several *IL10* promoter polymorphisms have been extensively studied. Some variants
409 were significantly associated with high PBMC proliferative responses to *Onchocerca*
410 *volvulus* antigen.⁶⁶ One of these promoter variants, the G-1082A was also associated with
411 immune-related diseases including type 2 diabetes, multiple sclerosis, and asthma.⁶⁷
412 Moreover, the same variant was associated with pediatric asthma.⁶⁸ In an endemic area for *S.*
413 *mansoni* alleles at the three promoter SNPs were associated with high tIgE levels in the same
414 direction as in atopic individuals, but not with egg counts. IL10 promoter polymorphisms
415 appear to influence non-specific tIgE levels, but not schistosomiasis-specific immunity.⁷

416 Genetic polymorphisms in *TGFB1* are associated with airway responsiveness and
417 exacerbations in children with asthma.⁶⁹ Common variants in *TGFB1* gene affect both
418 asthma/allergy and helminth infections. We demonstrated a negative association between
419 rs1800470 (C allele), atopic wheezing and markers of allergy. In contrast, a positive
420 association was observed between the haplotype ACCA and *T. trichiura* and *A. lumbricoides*
421 infection. This later haplotype was also associated with increased IL10 production.⁷⁰

422 The main cellular source of both IL10 and TGFB1 are T_{regs}, critical for the
423 maintenance of immune homeostasis. The activation of FOXP3 transcriptional factor is
424 pivotal for T_{regs} function. The human FOXP3 gene is located on the X-chromosome
425 (Xp11.23) and because of sex differences among X-variants, insufficient efforts have been
426 made to include X variants in GWAS. Ppolymorphisms in the FOXP3 gene have been
427 evaluated in association studies for allergy⁷¹ but only a few studies on asthma have been
428 reported. A study reported a significant interaction between SNPs in FOXP3-IL2R genes and
429 sIgE for worm eggs and asthma.⁷² The SNPs rs2294019 and rs5906761 were associated with
430 the risk of egg sensitization only in females.⁷¹ The heterozygote genotype for rs3761547 was
431 a risk factor for allergic rhinitis, and this association was reproduced in gene-gene interaction
432 analysis with rs3761548.⁷²

433 The immune regulation of allergic disease results not only from protective
434 environmental factors including helminths, but also from genetic factors relating to *IL10*
435 production or hyperactivation of type 2 immune responses. From an evolutionary perspective,
436 the selective advantage acquired by humans able to mount an efficient protective immune
437 response to helminth infections may make them more vulnerable to atopy and asthma.

Insert Table 1.

Examples of helminth infections and the allergic-type inflammatory responses with which they are associated.

Treatment of allergic diseases with systemic corticosteroids at immunosuppressive doses increase the risk of opportunistic infections. The helminth reported to affect immune suppressed hosts most frequently is *Strongyloides stercoralis*, occasionally resulting in uncontrolled dissemination of the parasite in the potentially fatal hyper-infection syndrome. *Strongyloides* hyperinfection has been associated also with other immunosuppressive drugs, lymphomas, and infection with HTLV-1 virus.⁷³ Because of the presumed central role of IgE in protective immunity against helminth parasites, treatment of severe asthma with anti-IgE antibody raised concerns about risk of severe or disseminated helminth infections. A multicentre randomized controlled trial of omalizumab for the treatment of asthma and rhinitis was safe in a population at risk of STH infections, although there was a modest increase in geohelminth infection.⁷⁴ The same safety concerns will be present in populations at risk of helminthiasis for other immunomodulatory compounds for treatment of allergic diseases, particularly those targeting specific type 2 effector pathways such as anti-IL5 and anti-*IL13/IL4*.

Helminth infections induce cellular immune hyporesponsiveness.¹¹ Such hyporesponsiveness has been associated with suboptimal vaccine responses.^{75,76} Among pregnant women, soluble parasite antigens cross the placenta and modify fetal immune responses in such a way as to possibly affect vaccine responses in childhood.⁷⁷ Modification of the host immune response to helminths affects how humans respond immunologically to other pathogens such as those causing malaria⁷⁸ and tuberculosis,⁷⁹ however, effects on clinically measurable outcomes are less clear.

472

473

Reports have indicated possible benefits of helminth infections on autoimmune diseases, inflammatory bowel disease, and even in the metabolic syndrome.⁸⁰ For example, an inverse association between lymphatic filariasis and type II Diabetes was reported,⁸¹ and past infection with *S. japonicum* was associated with a lower prevalence of metabolic syndrome.⁸² Intestinal helminth infections were inversely associated with risk factors for cardiovascular diseases, such as body mass index and lipid levels.⁸³

483

484

485

An observational study of patients with multiple sclerosis, who had acquired gastrointestinal helminth infections, reported remission of multiple sclerosis for over 4 years. Patients infected with parasites had reduced inflammatory cytokine responses and enhanced production of *IL10* as well as *TGFB*. Six of these subjects were followed up and remission continued into the sixth year, when four patients were offered anthelmintic treatment due to gastrointestinal problems. Subsequently their multiple sclerosis activity resumed while *IL10* and *TGFB* levels declined.⁸⁴

486 Experimental infections of humans with live parasites employing either the pig
487 whipworm, *T. suis*, or the human hookworm, *N. americanus* have been reported.⁸⁵ The
488 premise is that the immune system can be modulated with amelioration or remission of the
489 inflammatory disease. In the case of treatment with *T. suis*, parasite eggs are administered
490 orally. Initial studies reported a beneficial effect on Crohn's disease and ulcerative colitis.⁸⁶
491 *T. suis* eggs have been used to treat other immune disorders. A randomized controlled trial
492 tested the efficacy of *T. suis* for the treatment allergic rhinitis in Denmark but showed no
493 efficacy. Although *T. suis* infection generated a measurable anti-parasite response, infection
494 did not affect allergen-specific responses.⁸⁷ Patients with Crohn's patients were infected with
495 *N. americanus*, with the majority showing improvements in symptom scores.⁸⁸ A trial of *N.*
496 *americanus* in patients with coeliac disease was unable to demonstrate clinical benefit.⁸⁹ A
497 small randomized control trial in patients with asthma showed no significant benefit of
498 hookworm infection on clinical symptoms, bronchial responsiveness or SPT reactivity.⁹⁰

499 What may be the reasons for the disappointing findings of clinical trials to date?
500 Experimental animal models have demonstrated helminth parasites reduce allergic reactivity,
501 but most studies have been designed to prevent the development of allergic reactivity rather
502 than treat established disease. Only a handful of studies have reported the effects of these
503 infections on already established allergic reactivity.⁹¹ Most of the experimental data available
504 suggest that once the allergic reaction is established, helminth infections can do little to revert
505 the disease process, raising the question whether there is any reasonable possibility of
506 obtaining benefit through infections of individuals with active disease. Nonetheless, there are
507 sufficient doubts with respect to optimal timing of treatment, the dose and systemic versus
508 non-systemic infections, to justify future well-designed and justified randomized-controlled
509 trials of helminth therapy for inflammatory conditions.

510

511 *Tests with helminth molecules as immunomodulatory candidates*

512 Recombinant proteins can reproduce the biological effects observed in infections with live
513 worms. In experimental models of inflammatory disease, recombinant proteins derived from
514 helminth molecules induce anti-inflammatory and inhibit pro-inflammatory cytokine
515 production, promote regulatory cell recruitment and immune deviation.⁹²

516 In mouse models, helminth ES molecules, and helminth-derived synthetic molecules
517 have shown usefulness in treating or preventing the development of inflammatory diseases
518 such as inflammatory bowel diseases, type 1 Diabetes, multiple sclerosis, rheumatoid arthritis
519 and asthma. The synthetic production of ES-derived immune modulators avoids concerns
520 raised by the use of live organisms.⁹³ Further, the molecule-based helminth treatment offers
521 the advantage of delivery directly to the site of pathology.

522 We present in Table 2 a summary of pre-clinical and clinical studies of helminth
523 molecules for the treatment of chronic inflammatory conditions affecting humans.

524 Insert Table 2.

525 Helminth molecule candidates for the treatment of inflammatory diseases.

526

527 **Discussion**

528 There is conflicting evidence of an inverse association between exposure to helminth
529 infections and human chronic inflammatory diseases including allergic conditions. A possible
530 causal relationship is supported largely by the findings from experimental animal models,
531 while evidence from human studies has been equivocal. Evidence from clinical trials of live
532 helminth parasites has been disappointing.

533 One explanation for the associations between allergy and helminths in
534 epidemiological studies is the genetic evolutionary advantage of mounting strong type 2
535 responses protective against helminth infection although increasing the risk of allergy.⁶⁵
536 Alternatively, the sort of environmental and unhygienic living conditions where parasite
537 infections are likely to occur also expose populations to multiple other microorganisms which
538 may contribute to the modulation of inflammatory responses.^{94,95} Moreover, there is evidence
539 that several other contextual factors not always controlled for in observational studies might
540 contribute to the inverse association between helminthes and allergy. Such factors include
541 diet, nutrition, obesity, gut microbiome, physical activity, exposure to air pollution, stress and
542 use of vaccines and antibiotics, all of which are related to an urbanized lifestyle, which has
543 clearly been an important risk factor for allergy.^{96,97}

544 How do we interpret the negative results of clinical trials of live helminth infections
545 when helminth infections or helminth-derived molecules have proved so effective in
546 controlling animal models of inflammatory diseases? The effects of helminth infections in
547 humans are related to parasite burden and duration of infection. Clearly, there are safety and
548 ethical concerns with treating humans with large infectious doses and maintaining infections
549 for period of years that may be required to induce clinically relevant immune modulatory
550 effects. Further, trials in humans have attempted to modify preexisting disease while most
551 animal models have studied the ability of helminths to prevent disease.

552

553 **Conclusions**

554 There is consolidated evidence from studies in humans for a negative association of helminth
555 infection with allergy, although the effect seems to vary by helminth species, parasite burden,
556 and age of infection. Helminth infections may also provoke symptoms of allergy, although

557 such allergic inflammation tends to be modulated during chronic infections. Experiments in
558 animal models of chronic inflammatory diseases have demonstrated the potential benefits of
559 helminth infection or the use of helminth-derived molecules against allergic disease, but
560 clinical trials in humans have been disappointing. We still have an inadequate understanding
561 of the complex interplay between helminths and allergy and there is a need for more studies
562 in humans and experimental studies in animal models to understand these interactions more
563 fully. Certainly, the exploitation of helminth-derived molecules for the treatment of
564 inflammatory conditions offers promising new avenues for research and development.

916

917

918 Clinical Notes Box I.

919 Notes of relevance for clinical allergy practice on immunopathology of helminth infections.

920

- 921 • *Accuracy of allergy testing*
922 when dealing with patients from endemic areas for helminth infections, an allergy workup
923 including specific IgE may be more sensitive than SPT, but in subjects with a very high
924 total IgE, *in vitro* tests may be false positive
- 925 • *Interpretation of total IgE and blood eosinophilia*
926 elevated total IgE and peripheral blood eosinophilia may indicate helminth infection
- 927 • *Potential reduction in efficacy of vaccines for prevention of infectious diseases*
928 it is important children and adults are free of worms for optimal efficacy of vaccines
- 929 • *Risks of prolonged use of systemic corticosteroids and immunobiological suppressors of*
930 *T2 inflammation mediators (Anti-IgE, Anti-IL5, Anti-IL4/13)*

931 treatment of severe asthma with continuous oral corticosteroids, *Anti-IgE*, *Anti-IL5* or
932 *Anti-IL4/13* poses risk of helminth superinfection. It is advisable to observe the patient
933 closely, investigate and treat if necessary, when living or coming from a region that is
934 endemic for worms.

935

936

937 Clinical Notes Box II.

938 Note of relevance on protection against allergy and other chronic diseases

939

- 940 • *Inverse association between helminth infection and allergy and other chronic*
941 *diseases* there is compelling evidence of a strong inverse association between
942 infection by various helminths and biomarkers of chronic inflammatory diseases and
943 allergy
- 944 • *A causal association is plausible*
945 a direct causality is plausible, taking into consideration experimental studies in animal
946 models and humans
- 947 • *No robust association between helminth infection and protection against diseases*
948 we found no robust evidence for causal associations between helminth infection and
949 clinically relevant protection against disease, however
- 950 • *Exposure to helminths occur in a diverse environment that may be itself protective*
951 in the real world, exposure to helminths often occur in a markedly different
952 environmental, ethnical and lifestyle context, including contrasts in ancestrality,
953 physical activity, diet, nutrition, stress, exposure to air pollution and to
954 microorganisms
- 955 • *A protective environment may overshadow the effects of helminth infection*
956 the potential influence of multiple factors in the health and diseases balance may
957 overshadow the impact of exposure to parasites
- 958 • *The inverse associations may not be directly causal*
959 the inverse associations between helminth infections and biomarkers of chronic
960 inflammatory diseases and allergy may not be directly causal, but linked to conditions
961 related to parasite infections

962

963 FIGURE LEGEND

964

965 Figure 1. Typical features of a rural household in a village in the municipality of
966 Conde, Brazil, in which the prevalence of helminth infections was 83.5% (Grant et al,
967 2008) (picture taken in 2005).

968

969 Figure 2. Typical urban underserved neighborhood of Salvador, Brazil, in which the
970 prevalence of helminth infection among children was below 20% (Alcantara-Neves et
971 al, 2011).

972

973 Figure 3. Schematic representation summarizing the findings from epidemiological
974 studies on the relationships between helminth parasites, atopy and asthma.

975

976 Figure 4. Helminths suppress autoimmunity and allergy via type 2 or regulatory
977 immune response. Immunomodulatory molecules (IMs) of parasites activate innate
978 immune cells that promote either Th2 or T_{reg} responses. IMs that induce TGFβ, IL10
979 by dendritic cells (DCs) or macrophages (Mφ) prime IL10 or TGFβ-producing T_{reg}
980 cells suppress Th2 responses, Th1 or Th17 responses. A separate set of helminth-
981 derived IMs activate type 2 innate cells, including basophils, M2 macrophages, and
982 type 2 innate lymphoid cells (ILC2) and induce innate IL-4 production, which drives
983 differentiation of Th2 cells. Th2 cells and type 2 innate immune cells can suppress
984 Th1 and Th17 responses (modified from Finlay et al, 2014⁴⁸).

985

986 Figure 5. Pathway analysis using Panther 11⁸⁷ version for the top SNPs associated
987 in GWAS for asthma to date.

Helminth infection	Allergic-type reactions and syndromes
Intestinal helminths <i>Ascaris lumbricoides</i> <i>Trichiura trichiura</i> Hookworm <i>Strongyloides stercoralis</i> <i>Enterobius vermicularis</i>	'Asthma-like' syndrome Tropical dysentery syndrome Ground itch/allergic enteritis Larva currens/urticaria/'asthma-like' syndrome Itchy anus
Schistosomiasis <i>S. mansoni</i> <i>S. haematobium</i> <i>S. japonicum</i>	Cercarial dermatitis/acute schistosomiasis/urticaria/ 'asthma-like' syndrome
Filariasis <i>Wuchereria bancrofti</i> <i>Onchocerca volvulus</i> <i>Loa loa</i>	Tropical pulmonary eosinophilia/acute lymphangitis Sowda/acute popular onchodermatitis/punctate keratitis Calabar swellings
Others <i>Toxocara</i> spp. <i>Anisakis</i> spp. <i>Paragonimus</i> spp. <i>Trichinella spiralis</i> <i>Echinococcus granulosus</i> <i>Ancylostoma braziliense</i>	Visceral larva migrans/'asthma-like' syndrome 'gastroallergic'/asthma-like syndrome/urticaria/anaphylaxis Asthma-like syndrome Acute trichinosis Acute anaphylaxis associated with rupture of cyst Cutaneous larva migrans

Table 1. Examples of helminth infections and the allergic-type inflammatory responses with which they are associated.

Table 2. Helminth molecule candidates for the treatment of inflammatory diseases.

Molecule	Study phase	Treatment	Results	References
Excretory/secretory-62	animal models	rheumatoid arthritis and systemic lupus erythematosus	reduce disease severity and progression	Rodgers et al, 2015 ¹⁵⁹
<u>Neutrophil inhibitory Factor (NiF)</u>	animal models and humans (Phase I/II)	acute stroke, allergen induced lung inflammation and diabetic retinopathy	no benefit in human stroke, favourable results in mouse models of lung inflammation and retinopathy	Krams et al, 2003; ¹⁶⁰ Schnyder-Candrian et al, 2012; ¹⁶¹ Veenstra et al, 2013 ¹⁶²
Migration inhibitory Factor (MiF)	animal models	colitis and allergic airway inflammation	favorable	Cho et al, 2011; ¹⁶³ Park et al, 2009 ¹⁶⁴
Cystatins	animal models	colitis and allergic airway inflammation	favorable	Whelan et al, 2014 ¹⁶⁵
Helminth defense molecules	animal models	LPS-induced inflammation	favorable	Alvarado et al, 2017 ¹⁶⁶
Anti-inflammatory protein-2 (AIP-2)	animal models	model of asthma	favorable	Navarro et al, 2016 ¹⁶⁷
TGF β Pathway Manipulation	studies <i>in vitro</i>	molecular biology stage	promising	Freitas et al, 2009 ¹⁶⁸
Prostaglandin E2 (PGE2)	studies <i>in vitro</i>	molecular biology stage	promising	Liu et al, 2013 ¹⁶⁹
ShkT domains	animal models and humans (Phase I and II)	human psoriasis	unknown results	Beeton et al, 2006 ¹⁷⁰ and NCT02435342
AcK1 and BmK1	studies <i>in vitro</i>	immunology stage	promising	Steinfelder et al, 2016 ¹⁷¹
