

Some relations concerning k -chordal and k -tangential polygons

MIRKO RADIĆ*

Abstract. In papers [6] and [7] the k -chordal and the k -tangential polygons are defined and some of their properties are proved. In this paper we shall consider some of their other properties. Theorems 1-4 are proved.

Key words: geometrical inequalities, k -chordal polygon, k -tangential polygon

1. Preliminaries

A polygon with vertices $A_1 \dots A_n$ (in this order) will be denoted by $A_1 \dots A_n$ and the lengths of the sides of $A_1 \dots A_n$ will be denoted by a_1, \dots, a_n , where $a_i = |A_i A_{i+1}|$, $i = 1, 2, \dots, n$. For the interior angle at the vertex A_i we write α_i or $\angle A_i$, i.e. $\angle A_i = \angle A_{n-1+i} A_i A_{i+1}$, $i = 1, \dots, n$. Of course, indices are calculated modulo n .

For convenience we list some definitions given in [6] and [7].

Definition 1. Let $\underline{A} = A_1 \dots A_n$ be a chordal polygon and let C be its circumcircle. By S_{A_i} and \widehat{S}_{A_i} we denote the semicircles of C such that

$$S_{A_i} \cup \widehat{S}_{A_i} = C, \quad A_i \in S_{A_i} \cap \widehat{S}_{A_i}.$$

The polygon \underline{A} is said to be of the first kind if the following is fulfilled:

1. all vertices $A_1 \dots A_n$ do not lie on the same semicircle,
2. for every three consecutive vertices A_i, A_{i+1}, A_{i+2} it holds

$$A_i \in S_{A_{i+1}} \Rightarrow A_{i+2} \in \widehat{S}_{A_{i+1}}$$

3. any two consecutive vertices A_i, A_{i+1} do not lie on the same diameter.

Definition 2. Let $\underline{A} = A_1 \dots A_n$ be a chordal polygon and let k be a positive integer. The polygon \underline{A} is said to be a k -chordal polygon if it is of the first kind and if there holds

$$\sum_{i=1}^n \angle A_i C A_{i+1} = 2k\pi, \quad (1)$$

*Department of Mathematics, University of Rijeka, Omladinska 14, HR-51 000 Rijeka, Croatia

where C is the centre of the circumcircle of the polygon \underline{A} .

Using (1) it is easy to see that the angles of a k -chordal polygon $A_1 \dots A_n$ satisfy the relation:

$$\sum_{i=1}^n \angle A_i = (n - 2k)\pi. \quad (2)$$

Definition 3. Let $\underline{A} = A_1 \dots A_n$ be a tangential polygon and let k be a positive integer so that $k \leq \lfloor \frac{n-1}{2} \rfloor$, that is, $k \leq \frac{n-1}{2}$ if n is odd, and $k \leq \frac{n-2}{2}$ if n is even. The polygon \underline{A} will be called a k -tangential polygon if any two of its consecutive sides have only one common point, and if there holds

$$\beta_1 + \dots + \beta_n = (n - 2k)\frac{\pi}{2}, \quad (3)$$

where $2\beta_i = \angle A_i$, $i = 1, \dots, n$.

Consequently, a tangential polygon \underline{A} is k -tangential if

$$\varphi_1 + \dots + \varphi_n = 2k\pi, \quad (4)$$

where $\varphi_i = \angle A_i C A_{i+1}$ and C is the centre of the circle inscribed into the polygon \underline{A} .

The integer k in relations (1)-(4) can be at most $\frac{n-1}{2}$ if n is odd and $\frac{n-2}{2}$ if n is even.

Remark 1. In the following considerations we shall denote the angles β_1, \dots, β_n such that

$$\beta_i = \angle C A_i A_{i+1}, \quad \text{if it is a question of a chordal polygon,}$$

$$\beta_i = \frac{1}{2}\angle A_i, \quad \text{if it is a question of a tangential polygon.}$$

2. Some inequalities concerning the radius of k -chordal and k -tangential polygons

At first we prove some results concerning a k -chordal polygon.

Theorem 1. Let a_1, \dots, a_n be the lengths of the sides of a k -chordal polygon $\underline{A} = A_1 \dots A_n$ and let $a_1 = \min\{a_1 \dots a_n\}$. If there exist angles $\gamma_1, \dots, \gamma_n$ such that

$$\gamma_1 + \dots + \gamma_n = (n - 2k)\frac{\pi}{2}, \quad 0 < \gamma_i < \frac{\pi}{2}, \quad i = 1, \dots, n, \quad (5)$$

$$a_1 \sin \gamma_1 = a_2 \sin \gamma_2 = \dots = a_n \sin \gamma_n. \quad (6)$$

Then

$$2r > \frac{\sum_{i=1}^n a_i^2}{\sum_{i=1}^n a_i - \frac{1}{2} \left(\sum_{i=1}^n \frac{1}{a_i} \right) a_1^2 \sin^2(n-2k) \frac{\pi}{2n}}, \quad (7)$$

where r is the radius of the circumcircle of the polygon \underline{A} .

Proof. Since $\beta_i = \angle CA_i A_{i+1}$, $i = 1, \dots, n$, we have the following relations

$$\beta_1 + \dots + \beta_n = (n-2k) \frac{\pi}{2}, \quad 0 < \beta_i < \frac{\pi}{2}, \quad i = 1, \dots, n \quad (8)$$

$$2r \cos \beta_i = a_i, \quad i = 1, \dots, n \quad (9)$$

from which it follows

$$2ra_i \cos \beta_i = a_i^2, \quad i = 1, \dots, n$$

$$2r = \frac{\sum_{i=1}^n a_i^2}{\sum_{i=1}^n a_i \cos \beta_i}. \quad (10)$$

In addition to the angles β_1, \dots, β_n there are infinitely many angles $\gamma_1, \dots, \gamma_n$ such that

$$\gamma_1 + \dots + \gamma_n = (n-2k) \frac{\pi}{2}, \quad 0 < \gamma_i < \frac{\pi}{2}, \quad i = 1, \dots, n.$$

We shall prove that $\sum_{i=1}^n a_i \cos \gamma_i = \text{maximum}$ if the angles $\gamma_1, \dots, \gamma_n$ satisfy

$$a_1 \sin \gamma_1 = a_2 \sin \gamma_2 = \dots = a_n \sin \gamma_n.$$

First we shall prove the following lemma.

Lemma 1. *If a_1 and a_2 are positive numbers and*

$$\gamma_1 + \gamma_2 = s, \quad 0 < s < \pi, \quad 0 < \gamma_i < \frac{\pi}{2}, \quad i = 1, 2$$

then the function $f(\gamma_1, \gamma_2) = a_1 \cos \gamma_1 + a_2 \cos \gamma_2$ assumes maximum if $a_1 \sin \gamma_1 = a_2 \sin \gamma_2$.

Proof. Let $g(\gamma_1) = a_1 \cos \gamma_1 + a_2 \cos(s - \gamma_1)$, then

$$g'(\gamma_1) = -a_1 \sin \gamma_1 + a_2 \sin(s - \gamma_1),$$

$$g''(\gamma_1) = -a_1 \cos \gamma_1 - a_2 \cos(s - \gamma_1) < 0,$$

$$a_1 \sin \gamma_1 + a_2 \sin(s - \gamma_1) = 0 \quad \Rightarrow \quad a_1 \sin \gamma_1 = a_2 \sin(s - \gamma_2).$$

□

From the above lemma it is clear that the sum $\sum_{i=1}^n a_i \cos \gamma_i$ assumes maximum if for each sum

$$a_i \cos \gamma_i + a_j \cos \gamma_j, \quad i, j \in \{1, \dots, n\}$$

there holds $a_i \sin \gamma_i = a_j \sin \gamma_j$, since we can put $\gamma_i + \gamma_j = s$.

Now, we are going to prove that the inequality (7) is valid if (6) is fulfilled. Based on the assumption that equations (6) exist, we can write

$$a_i \sin \gamma_i = \lambda, \quad i = 1, \dots, n$$

from which it follows

$$\cos \gamma_i = \sqrt{1 - \left(\frac{\lambda}{a_i}\right)^2} < 1 - \frac{1}{2} \left(\frac{\lambda}{a_i}\right)^2, \quad i = 1, \dots, n,$$

$$\sum_{i=1}^n a_i \left[1 - \frac{1}{2} \left(\frac{\lambda}{a_i}\right)^2\right] > \sum_{i=1}^n a_i \cos \gamma_i \geq \sum_{i=1}^n a_i \cos \beta_i$$

so that instead of (10) we can write

$$2r > \frac{\sum_{i=1}^n a_i^2}{\sum_{i=1}^n a_i - \frac{1}{2} \left(\sum_{i=1}^n \frac{1}{a_i}\right) \lambda^2}. \quad (11)$$

Since $\gamma_i = \arcsin \frac{\lambda}{a_i}$, $i = 1, \dots, n$ we have the equation

$$\sum_{i=1}^n \arcsin \frac{\lambda}{a_i} = (n - 2k) \frac{\pi}{2}, \quad (12)$$

or

$$\left(\frac{\lambda}{a_1} + \dots + \frac{\lambda}{a_n}\right) + \frac{1}{6} \left[\left(\frac{\lambda}{a_1}\right)^3 + \dots + \left(\frac{\lambda}{a_n}\right)^3 \right] + \dots = (n - 2k) \frac{\pi}{2}. \quad (13)$$

Since by assumption $a_1 = \min\{a_1, \dots, a_n\}$, from (13) it follows that

$$\left(\frac{\lambda}{a_1} + \dots + \frac{\lambda}{a_1}\right) + \frac{1}{6} \left[\left(\frac{\lambda}{a_1}\right)^3 + \dots + \left(\frac{\lambda}{a_1}\right)^3 \right] + \dots \geq (n - 2k) \frac{\pi}{2}$$

or

$$\arcsin \frac{\lambda}{a_1} \geq (n - 2k) \frac{\pi}{2n}.$$

Hence

$$\lambda \geq a_1 \sin(n - 2k) \frac{\pi}{2n}. \tag{14}$$

Now using (11) and (14) we readily get (7). So, *Theorem 1* is proved. \square

Before stating some of its corollaries here is an example. If $A_1 \dots A_5$ is a 1-chordal pentagon as shown in *Figure 1*, then there are angles $\gamma_1, \dots, \gamma_5$ such that

$$\gamma_1 + \dots + \gamma_5 = (5 - 2) \frac{\pi}{2}, \quad a_1 \sin \gamma_1 = \dots = a_5 \sin \gamma_5$$

if instead of the drawn circles these can be drawn greater such that the above equalities are valid. (For these drawn ones it is $\gamma_1 + \dots + \gamma_5 < \frac{3\pi}{2}$. Let us remark that in the case when a side is small enough, then there are no angles $\gamma_1, \dots, \gamma_5$ such that $\gamma_1 + \dots + \gamma_5 = \frac{3\pi}{2}$.)

Figure 1.

Now we state some of the corollaries of *Theorem 1*.

Corollary 1. *There are angles $\gamma_1, \dots, \gamma_n$ such that (5) and (6) hold if and only if*

$$\frac{a_1}{H(a_1, \dots, a_n)} + \frac{1}{6} \frac{a_1^3}{H(a_1^3, \dots, a_n^3)} + \dots \geq (n - 2k) \frac{\pi}{2n} \tag{15}$$

where $H(a_1^i, \dots, a_n^i)$ is the harmonic mean of a_1^i, \dots, a_n^i .

Proof. It is clear from (13) since λ may be at most a_1 . \square

Corollary 2. A sufficient condition for the existence of the angles $\gamma_1, \dots, \gamma_n$ such that (5) and (6) hold is the inequality

$$a_1 \geq H(a_1, \dots, a_n) \sin(n-2k) \frac{\pi}{2n} \quad (16)$$

Proof. If (16) holds, then obviously (15) holds, too. Namely, if

$$\frac{a_1}{H(a_1, \dots, a_n)} + \frac{1}{6} \left[\frac{a_1}{H(a_1, \dots, a_n)} \right]^3 + \dots \geq (n-2k) \frac{\pi}{2n},$$

then certainly (15) is valid because of the property of the arithmetics mean. \square

Corollary 3. If there exists a k -chordal polygon whose sides have the lengths $\frac{1}{a_1}, \dots, \frac{1}{a_n}$ and $\frac{2k}{n} \geq \sin(n-2k) \frac{\pi}{2n}$, then there exist angles $\gamma_1, \dots, \gamma_n$ such that (5) and (6) hold.

Proof. We shall use Corollary 2 in [6]. If a_1, \dots, a_n are the lengths of the sides of the k -chordal polygon \underline{A} , then

$$\sum_{i=1}^n a_i > 2ka_j, \quad j = 1, \dots, n. \quad (17)$$

If $\frac{1}{a_1}, \dots, \frac{1}{a_n}$ are also the lengths of the sides of a k -chordal polygon, then

$$\frac{1}{a_1} + \dots + \frac{1}{a_n} > \frac{2k}{a_1}$$

or

$$a_1 > \frac{2k}{n} H(a_1, \dots, a_n). \quad (18)$$

Accordingly, if $\frac{2k}{n} \geq \sin(n-2k) \frac{\pi}{2n}$ then (16) is valid. \square

Corollary 4. If n is odd and k is maximal, i.e. $k = \frac{n-1}{2}$, then there exist the angles $\gamma_1, \dots, \gamma_n$ such that (5) and (6) hold.

Proof. If $k = \frac{n-1}{2}$, then equation (5) can be written as

$$\gamma_1 + \dots + \gamma_n = \frac{\pi}{2},$$

and obviously there is λ such that $\sum_{i=1}^n \arcsin \frac{\lambda}{a_i} = \frac{\pi}{2}$. \square

Corollary 5. If $n = 3$ and a, b, c are the lengths of the sides of an acute triangle, then

$$2r > \frac{a^2 + b^2 + c^2}{a + b + c - \frac{3}{8} \frac{a^2}{H(a, b, c)}} \quad (19)$$

where $a = \min\{a, b, c\}$. In connection with this, the following remarks may be interesting.

Remark 2. Since

$$\sqrt{1 - \left(\frac{\lambda}{a}\right)^2} < 1 - \frac{1}{2} \left(\frac{\lambda}{a}\right)^2,$$

inequality (19) follows from the inequality

$$2r \geq \frac{a^2 + b^2 + c^2}{\sqrt{a^2 - \lambda^2} + \sqrt{b^2 - \lambda^2} + \sqrt{c^2 - \lambda^2}}, \quad (20)$$

where $\lambda = a \sin \frac{\pi}{6}$. Here the equality appears for $a = b = c$.

Analogously holds for inequality (7).

Remark 3. In the case when $n = 3$, Corollary 4 can be also proved as follows:

$$\begin{aligned} \gamma_1 + \gamma_2 + \gamma_3 &= \frac{\pi}{2}, \\ \cos(\gamma_1 + \gamma_2) &= \sin \gamma_3, \\ \cos \gamma_1 \cos \gamma_2 &= \sin \gamma_1 \sin \gamma_2 + \sin \gamma_3, \\ \sqrt{1 - \left(\frac{\lambda}{a}\right)^2} \sqrt{1 - \left(\frac{\lambda}{b}\right)^2} &= \frac{\lambda}{a} \frac{\lambda}{b} + \frac{\lambda}{c}, \\ 2abc\lambda^3 + (a^2b^2 + b^2c^2 + c^2a^2)\lambda^2 - a^2b^2c^2 &= 0. \end{aligned}$$

The above equation in λ has one positive root and it lies between 0 and a since $f(0) < 0, f(a) > 0$, where $f(\lambda) = 2abc\lambda^3 + (a^2b^2 + b^2c^2 + c^2a^2)\lambda^2 - a^2b^2c^2$. For example, if $a_1 = a = 7, a_2 = b = 8, a_3 = c = 10$ (Figure 2), then $\lambda = 4.063986$ and $\gamma_1 = 35.49060749, \gamma_2 = 30.53058949, \gamma_3 = 23.97880303$.

Figure 2.

Analogously holds in the case when $n > 3$. But in this case it may be very difficult to solve the equation obtained in λ . So, if $A_1 \dots A_5$ is a 2-chordal pentagon, then we have

$$\gamma_1 + \gamma_2 + \gamma_3 + \gamma_4 + \gamma_5 = \frac{\pi}{2},$$

$$\cos(\gamma_1 + \gamma_2 + \gamma_3 + \gamma_4) = \sin \gamma_5,$$

$$\cos(\gamma_1 + \gamma_2) \cos(\gamma_3 + \gamma_4) - \sin(\gamma_1 + \gamma_2) \sin(\gamma_3 + \gamma_4) = \sin \gamma_5,$$

and so on. But it may be interesting that using the expressions

$$\sin \gamma_i = \frac{\lambda}{a_i}, \quad \cos \gamma_i = \sqrt{1 - \left(\frac{\lambda}{a_i}\right)^2}, \quad i = 1, \dots, 5$$

we obtain the equation which has a unique positive solution λ .

Corollary 6. *Let (for simplicity) in equation (13) in the case when $n = 4$ there be written a, b, c, d instead of a_1, a_2, a_3, a_4 , and let $a = \min\{a, b, c, d\}$. Then there are angles $\gamma_1, \gamma_2, \gamma_3, \gamma_4$ such that (5) and (6) hold in the case when $n = 4$ if and only if*

$$\frac{a^2}{2} \leq \frac{u}{v} \leq a^2,$$

where

$$u = -\frac{1}{a^4} - \frac{1}{b^4} - \frac{1}{c^4} - \frac{1}{d^4} + \frac{2}{a^2b^2} + \frac{2}{a^2c^2} + \frac{2}{a^2d^2} + \frac{2}{b^2c^2} + \frac{2}{b^2d^2} + \frac{2}{c^2d^2} + \frac{8}{abcd},$$

$$v = \frac{4}{a^2b^2c^2} + \frac{4}{b^2c^2d^2} + \frac{4}{c^2d^2a^2} + \frac{4}{d^2a^2b^2} + \frac{4}{a^3bcd} + \frac{4}{ab^3cd} + \frac{4}{abc^3d} + \frac{4}{abcd^3}.$$

Proof. From $\gamma_1 + \gamma_2 + \gamma_3 + \gamma_4 = \pi$, $a \sin \gamma_i = \lambda$, $i = 1, 2, 3, 4$, using the equality

$$\cos(\gamma_1 + \gamma_2) = -\cos(\gamma_3 + \gamma_4),$$

it can be found that

$$4 \left(1 - \frac{\lambda^2}{a^2}\right) \left(1 - \frac{\lambda^2}{b^2}\right) \left(1 - \frac{\lambda^2}{c^2}\right) \left(1 - \frac{\lambda^2}{d^2}\right)$$

$$= \left[\left(1 - \frac{\lambda^2}{a^2}\right) \left(1 - \frac{\lambda^2}{b^2}\right) + \left(1 - \frac{\lambda^2}{c^2}\right) \left(1 - \frac{\lambda^2}{d^2}\right) + \frac{\lambda^4}{a^2b^2} + \frac{\lambda^4}{c^2d^2} + \frac{2\lambda^4}{abcd} \right]^2$$

from which it follows that

$$u\lambda^4 - v\lambda^6 = 0.$$

Consequently, $\lambda = \sqrt{\frac{u}{v}}$. Let us remark that by (14), $\lambda \geq \frac{a\sqrt{2}}{2}$. □

In connection with this, let us remark that $\sqrt{u} = 4$ area of the chordal quadrangle whose sides have the lengths $\frac{1}{a}, \frac{1}{b}, \frac{1}{c}, \frac{1}{d}$.

Corollary 7. *The value λ given by (13) satisfies the following condition*

$$\lambda \leq H(a_1, \dots, a_n) \sin(n - 2k) \frac{\pi}{2n}. \quad (21)$$

Proof. Using (13) by the appropriate property of the arithmetic mean we get the inequality

$$n \frac{\frac{\lambda}{a_1} + \dots + \frac{\lambda}{a_n}}{n} + \frac{1}{6} n \left(\frac{\frac{\lambda}{a_1} + \dots + \frac{\lambda}{a_n}}{n} \right)^3 + \dots \leq (n - 2k) \frac{\pi}{2}$$

or

$$\arcsin \frac{\frac{\lambda}{a_1} + \dots + \frac{\lambda}{a_n}}{n} \leq (n - 2k) \frac{\pi}{2n},$$

from which it follows that (21) is valid. \square

Thus, the solution in λ of equation (13) cannot exceed the right-hand side of (21).

If λ is the solution of equation (13), then from (10), that is, from

$$2r \geq \frac{\sum_{i=1}^n a_i^2}{\sum_{i=1}^n a_i \cos \gamma_i} \quad \text{or} \quad 2r \geq \frac{\sum_{i=1}^n a_i^2}{\sum_{i=1}^n \sqrt{a_i^2 - a_i^2 \sin^2 \gamma_i}}$$

we have

$$2r \geq \frac{\sum_{i=1}^n a_i^2}{\sum_{i=1}^n \sqrt{a_i^2 - \lambda^2}}, \quad (22)$$

$$2r > \frac{\sum_{i=1}^n a_i^2}{\sum_{i=1}^n a_i \left[\sqrt{1 - \frac{1}{2} \left(\frac{\lambda}{a_i} \right)^2} \right]}, \quad (23)$$

The equality can appear in (22), but not in (23).

Let us consider the case when

$$\lambda = H(a_1, \dots, a_n) \sin(n - 2k) \frac{\pi}{2n} \quad (24)$$

Of course, we have such case when a k-chordal polygon is equilateral. Namely, then (22) can be written as

$$2r = \frac{a}{\cos(n - 2k) \frac{\pi}{2n}}, \quad (25)$$

and this is true since by this the diameter of a k -chordal equilateral polygon whose sides have the length a is given.

The following theorem is concerned with the radius of a k -tangential polygon.

Theorem 2. *Let $\underline{A} = A_1 \dots A_n$ be a given k -tangential polygon and let t_1, \dots, t_n be the lengths of its tangents. Then*

$$\left(\frac{1}{t_1} + \dots + \frac{1}{t_n} \right) \cos \left[(n-2k) \frac{\pi}{2n} \right] > 2k \left(1 - \frac{2k}{n} \right) \frac{1}{r}, \quad (26)$$

where r is the radius of the circle inscribed into \underline{A} .

Proof. Let β_1, \dots, β_n be the angles such that

$$\beta_i = \angle CA_i A_{i+1}, \quad i = 1, \dots, n.$$

Then by Theorem 1 from paper [6]

$$\sum_{i=1}^n \cos \beta_i > 2k \cos \beta_j, \quad j = 1, \dots, n.$$

From this (since $r = t_j \operatorname{tg} \beta_j$) it follows that

$$r \sum_{i=1}^n \cos \beta_i > 2kt_j \sin \beta_j, \quad j = 1, \dots, n \quad (27)$$

or

$$\frac{r}{2k} \left(\frac{1}{t_1} + \dots + \frac{1}{t_n} \right) \sum_{i=1}^n \cos \beta_i > \sum_{j=1}^n \sin \beta_j \quad (28)$$

Since $\sin(\pi x) > 2x$ if $0 < x < \frac{1}{2}$ and $\sin \alpha > \frac{2}{\pi} \alpha$ if $0 < \alpha < \frac{\pi}{2}$ (see proof of Theorem 1. in [6]), we have

$$\sum_{j=1}^n \sin \beta_j > \frac{2}{\pi} (\beta_1 + \dots + \beta_n) = n - 2k. \quad (29)$$

Also we have

$$\sum_{i=1}^n \cos \beta_i \leq n \cos(n-2k) \frac{\pi}{2n} \quad (30)$$

since the sum $\sum_{i=1}^n \cos \beta_i$ is maximal when $\beta_1 = \dots = \beta_n$. From (28), (29) and (30) we get (26). \square

Theorem 3. *Let $\underline{A} = A_1 \dots A_n$ be a k -chordal polygon and let $a_1 \dots a_n$ be the lengths of its sides. If n is even and the lengths b_1, \dots, b_n are such that*

$$a_i^2 + b_i^2 = 4r^2, \quad i = 1, \dots, n$$

where r is the radius of the circle circumscribed to \underline{A} , then there is an $(\frac{n}{2} - k)$ -chordal polygon with the property that b_1, \dots, b_n are lengths of its sides and that the radius of its circumscribed circle is the same as the radius of the circumcircle of \underline{A} .

Proof. If \underline{A} is a k -chordal polygon, then

$$\sum_{i=1}^n \beta_i = (n - 2k) \frac{\pi}{2}, \quad \beta_i = \angle CA_i A_{i+1}, \quad i = 1, \dots, n$$

where C is the centre of the circle circumscribed to \underline{A} .

Let $\underline{B} = B_1 \dots B_n$ be a polygon such that

$$B_i = A_i, \quad i = 1, 3, \dots, n - 1$$

$$B_i = A'_i, \quad i = 2, 4, \dots, n$$

where C is the midpoint of $A_i A'_i$, $i = 2, 4, \dots, n$. Then the polygon \underline{B} is an $(\frac{n}{2} - k)$ -chordal polygon since

$$\sum_{i=1}^n \angle CB_i B_{i+1} = \sum_{i=1}^n \left(\frac{\pi}{2} - \beta_i \right) = n \frac{\pi}{2} - \sum_{i=1}^n \beta_i = n \frac{\pi}{2} - (n - 2k) \frac{\pi}{2} = \left[n - 2 \left(\frac{n}{2} - k \right) \right] \frac{\pi}{2}. \quad \square$$

Here is an example. See *Figure 3*. If $n = 6$ and $A_1 \dots A_6$ is a 1-chordal hexagon, then $B_1 \dots B_6$ is a 2-chordal hexagon.

Figure 3.

In the following theorem we shall use the symbol S_j^n introduced in [7] with the following meaning: If t_1, \dots, t_n are given lengths, then S_j^n is the sum of all $\binom{n}{j}$ products of the form $t_{i_1} \dots t_{i_j}$ where i_1, \dots, i_j are different indices of the set $\{1, \dots, n\}$, that is

$$S_j^n = \sum_{1 \leq i_1 < \dots < i_j \leq n} t_{i_1} \dots t_{i_j}.$$

Also we shall use Theorem 2 proved in [7]:
Let $n \geq 3$ be any given odd number. Then

$$S_1^n r^{n-1} - S_3^n r^{n-3} + S_5^n r^{n-5} - \dots + (-1)^s S_n^n = 0,$$

$$S_1^{n+1} r^{n-1} - S_3^{n+1} r^{n-3} + S_5^{n+1} r^{n-5} - \dots + (-1)^s S_n^{n+1} = 0.$$

where $s = (1 + 3 + 5 + \dots + n) + 1$.

Theorem 4. Let $n \geq 4$ be an even number. If \underline{A} is a k -tangential polygon whose tangents have the lengths t_1, \dots, t_n , and if \underline{B} is the $(\frac{n}{2} - k)$ -tangential polygon whose tangents have the lengths $\frac{1}{t_1}, \dots, \frac{1}{t_n}$, then $r\rho = 1$, where r is the radius of the circle inscribed into \underline{A} and ρ is the radius of the circle inscribed into \underline{B} .

Proof. Let R_i^n be obtained from S_i^n putting $\frac{1}{t_i}$ instead of t_i and let $s = [1 + 3 + 5 + \dots + (n-1)] + 1$. Then

$$R_1^n \rho^{n-2} - R_3^n \rho^{n-4} + \dots + (-1)^s R_{n-1}^n = 0, \quad (31)$$

and if the equation

$$S_1^n r^{n-2} - S_3^n r^{n-4} + \dots + (-1)^s S_{n-1}^n = 0, \quad (32)$$

is divided by $t_1 \dots t_n$, we obtain

$$R_{n-1}^n r^{n-2} - R_{n-3}^n r^{n-4} + \dots + (-1)^s R_1^n = 0. \quad (33)$$

For example, if $n = 4$, we have the equation

$$(t_1 + t_2 + t_3 + t_4)r^2 - (t_1 t_2 t_3 + t_2 t_3 t_4 + t_3 t_4 t_1 + t_4 t_1 t_2) = 0,$$

from which, dividing by $t_1 t_2 t_3 t_4$, we get

$$R_3^4 r^2 - R_1^4 = 0 \quad \text{or} \quad R_1^4 \left(\frac{1}{r}\right)^2 - R_3^4 = 0,$$

where

$$R_3^4 = \frac{1}{t_1 t_2 t_3} + \frac{1}{t_2 t_3 t_4} + \frac{1}{t_3 t_4 t_1} + \frac{1}{t_4 t_1 t_2},$$

$$R_1^4 = \frac{1}{t_1} + \frac{1}{t_2} + \frac{1}{t_3} + \frac{1}{t_4}.$$

From (31) and (33) it is clear that for each r there is ρ such that $r\rho = 1$. Thus we have to prove that

$$r_k \rho_{\frac{n}{k}-k} = 1, \quad (34)$$

where r_k is the radius of the k -tangential n -gon whose tangents have the lengths t_1, \dots, t_n and $\rho_{\frac{n}{k}-k}$ is the radius of the $(\frac{n}{2}-k)$ -tangential n -gon whose tangents have the lengths $\frac{1}{t_1}, \dots, \frac{1}{t_n}$.

The proof is as follows. Let β_1, \dots, β_n and $\gamma_1, \dots, \gamma_n$ be corresponding angles, that is,

$$\beta_1 + \dots + \beta_n = (n-2k)\frac{\pi}{2},$$

$$\gamma_1 + \dots + \gamma_n = \left[n - \left(\frac{n}{2} - k \right) \right] \frac{\pi}{2},$$

$$t_i = r_k \operatorname{ctg} \beta_i, \quad \frac{1}{t_i} = \rho_{\frac{n}{2}-k} \operatorname{ctg} \gamma_i, \quad i = 1, \dots, n.$$

From $1 = (r_k \operatorname{ctg} \beta_i)(\rho_{\frac{n}{2}-k} \operatorname{ctg} \gamma_i)$ we see that $r_k \rho_{\frac{n}{2}-k} = 1$ iff $\gamma_i = \frac{\pi}{2} - \beta_i$. Hence we have

$$\sum_{i=1}^n \left(\frac{\pi}{2} - \beta_i \right) = n \frac{\pi}{2} - \sum_{i=1}^n \beta_i = n \frac{\pi}{2} - (n-2k)\frac{\pi}{2} = \left[n - 2 \left(\frac{n}{2} - k \right) \right] \frac{\pi}{2}.$$

And *Theorem 4* is proved. \square

Here are some examples. If $n = 4$, then $r_1 \rho_1 = 1$. If $n = 6$, then $r_1 \rho_2 = r_2 \rho_1 = 1$.

If $n = 8$, then $r_1 \rho_3 = r_2 \rho_2 = r_3 \rho_1 = 1$.

Especially, if $t_1 = \dots = t_n = 1$, then

$$r_k = \operatorname{tg} \left((n-2k) \frac{\pi}{2n} \right), \quad k = 1, \dots, \frac{n-2}{2},$$

$$\rho_{\frac{n}{2}-k} = \operatorname{tg} \left[\left(n - 2 \left(\frac{n}{2} - k \right) \right) \frac{\pi}{2n} \right] = \operatorname{tg} \frac{k\pi}{n},$$

$$r_k \rho_{\frac{n}{2}-k} = 1,$$

since $\operatorname{tg}(n-2k)\frac{\pi}{2n} = \operatorname{tg}\left(\frac{\pi}{2} - \frac{k\pi}{n}\right) = \operatorname{ctg}\frac{k\pi}{n}$.

So, if $n = 6$ and $k = 1$, the situation is shown in *Figure 4*, where $r_1 = \sqrt{3}$, $\rho_2 = \frac{1}{\sqrt{3}}$.
