Dissertation Director: Dr. Michael H. Nantz

Dr. Christopher T. Burns

Dr. Palaniappan Sethu

Dr. Francis P. Zamborini

DEDICATION

This dissertation is dedicated to my loving and supportive wife

Andrea Michelle Knipp,

and my wonderful children

Cooper Elliott Knipp

and

Libby Jane Knipp

ACKNOWLEDGEMENTS

I consider myself very lucky to have worked with Professor Michael H. Nantz as my advisor during my tenure at the University of Louisville. Any question or problem that I brought before him was immediately met with a torrent of well-contemplated ideas. But his brilliance was not limited to the research lab. Professor Nantz is a fantastic presenter and lecturer due to his ability to capture the audience's attention and provide thoughtful explanations in a way that best reflects the importance of the issue at hand. Dr. Nantz is also a natural leader who engenders respect while being fair and supportive. He always knew when he needed to push me to ensure that I reached my full potential.

I would also like to thank my committee members Professor Christopher Burns, Professor Francis Zamborini and Professor Palaniappan Sethu for their advice and direction throughout my graduate career.

During my time at the University of Louisville I was in several collaborations that provided me with the opportunity to work with researchers from disciplines outside of chemistry. I was lucky enough to

work with Professor Xiao-An Fu (University of Louisville, Department of Chemical Engineering), Professor Palaniappan Sethu (University of Alabama, Department of Cardiovascular Disease), Professor Ralf Schirmacher (University of Alberta, Department of Oncology) and Dr. Anu Puri (National Cancer Institute, Frederick, MD).

One of the best aspects of spending so many hours working in the lab was the friendship that I built with my group members. Xuan Huang and Souvik Biswas were always willing to offer advice and direction during my early days in the Nantz Lab. There is no doubt in my mind that I could never have made it through graduate school without the music, YouTube videos, hysterical lunches and thought-provoking conversations that I enjoyed with Sébastien Laulhé and Stephanie Mattingly. I have also become great friends with my younger lab mates Sadakatali Gori, Sara Biladeau, and Mumiye Ogunwale, as well as our post-doc Raju Mandapati. I would also like to thank the great undergraduate students Joseph Riddle, Ben Neltner, Olivetta Uradu, and Kristopher Nelson whom I trained.

I would like to thank the School of Interdisciplinary and Graduate Studies, the Institute for Molecular Diversity and Drug Design (IMD³), and the Office of Technology Transfer for their financial support and their belief in my research.

I also feel indebted to my high school teachers Jerry Rismiller and Nicholas Palmer who enthusiastically taught and awakened my desire to pursue a career in chemistry. I also want to thank my undergraduate advisor Professor A. J. C. Lewis Hogarth who provided me with a firm scientific foundation on which to build my career.

I want to express my gratitude also to my parents Ralph and Donna Knipp, my father- and mother-in-law Gregg and Reneé Dyke, my brother and his wife Caleb and Madoka Knipp, and my brother- and sister-in-law Aaron and Katherine Dyke. Their love, support and encouragement helped me reach my educational goals and emboldened me to persevere through the high and low points of graduate school.

Finally, my wife Andrea Knipp and my children Cooper Elliott and Libby Jane were my loudest cheerleaders. I thank them for enduring my absence through the long days and late nights, my frustration when my research was not going well and my stress as deadlines approached. Throughout my time at the University of Louisville they have believed in my aspirations and never ceased to build me up with words of encouragement.

ABSTRACT

TRIGGERED RELEASE OF SMALL MOLECULES FROM SOLID SUPPORTS USING HEAT OR AN APPLIED MAGNETIC FIELD

Ralph Jacob Knipp

November 19, 2014

The reaction of an aminoxy moiety (RONH_2) with an aldehyde or ketone carbonyl, an oximation reaction, results in the formation of robust oxime ether linkages. Oximation is a form of click chemistry and is chemoselective, occurs in a variety of solvents including water, and produces high yields with little to no purification.

We were inspired to exploit the advantages of oximation reactions by attaching aminoxy-functionalized molecules to solid supports, thus allowing us to employ aminoxy chemistry in ways that cannot be achieved using solution phase. Chapter 1 provides a review of aminoxy chemistry, its advantages over similar reactions and its multitude of applications. Chapter 2 describes the use of aminium aminoxy salts fixed to a silicon microreactor to enable the capture of volatile aldehydes and ketones from exhaled breath for early detection of lung cancer. Since only carbonyl compounds were

retained and thereby concentrated, the accurate measurements of scarce metabolite cancer markers were realized. Use of an acid-scavenging polymer transformed the aminium salt adducts into a volatile adducts, thus enabling analyses by both high-resolution mass spectrometry and gas chromatography.

Chapter 3 details our investigation into the use of thermally-induced intramolecular cyclization as a release mechanism. A kinetic study on the cyclization rates of a panel of thermally-labile linkers led to a demonstration involving such an aminoxy-functionalized linker covalently bonded within a poly(dimethylsiloxane) microchannel. After capture of an aldehyde-functionalized fluorophore that had been passed through the microchannel, the intramolecular cyclization release mechanism was induced by gentle warming to liberate the fluorescent oxime ether adduct. In Chapter 4 we applied our thermally-labile linkers to iron oxide nanoparticles in an effort to design an externally controlled drug delivery system. Fe_3O_4 nanoparticles generate heat when subjected to an alternating magnetic field (AMF), thus eliminating the need for an *in vivo* conventional heat source. During our investigation of AMF-induced release we discovered the unprecedented hydrolysis of robust chemical functionalities that occurs only at the nanoparticle-liquid interface. This discovery was exploited in the development of a delivery system capable of releasing oxime ether adducts.

In conclusion, this thesis describes novel innovations that can be immediately applied in a multitude of disciplines, from analytics to diagnoses and to drug delivery.

1.1. INTRODUCTION

Aminoxy chemistry is one of the true forms of click chemistry as described by Nobel laureate K. Barry Sharpless in 2001.¹ Sharpless recommended to follow Nature's lead, namely to synthesize substances by joining small segments together through heteroatom linkages (C–X–C) as opposed to focusing on carbon-carbon bond generation as the key assembly process. In order for a reaction to be considered click chemistry, it must be modular, wide in scope, have high yields, generate only inoffensive byproducts that can be removed without chromatography, use only readily available starting materials and reagents and be carried out either without solvents or with solvents such as water.

With such stringent specifications, only a handful of reactions can be labeled as click chemistry. Click chemistry reactions can be divided into four different classes: 1) cycloadditions of unsaturated species, especially 1,3-dipolar cycloaddition reactions, but also the Diels–Alder family of transformations; 2) additions to carbon–carbon multiple bonds, particularly oxidative cases such as epoxidation and aziridination; 3) carbonyl chemistry of the “non-aldol” type, such as formation of oxime ethers, hydrazones and amides; and 4) nucleophilic substitution chemistry of the S_N2 type, such as ring-opening reactions of strained heterocyclic electrophiles (*i.e.*, epoxides and aziridines).¹ Examples of these reactions can be seen in Figure 1.1.

1. Cycloadditions of unsaturated species

Azide-Alkyne Cycloadditions

2. Additions to carbon-carbon multiple bonds

3. Carbonyl chemistry of the “non-aldol” type

Aminoxy-Carbonyl Oximation

4. Ring opening reaction of strained heterocycles

Epoxide ring-opening

Figure 1.1. Generic examples of the four click chemistry classes of chemical transformations.

Though the azide-alkyne cycloaddition is one of the most popular forms of click chemistry, our lab has focused on the development of carbonyl chemistry of the “non-aldol” type, specifically aminoxy chemistry. Aminoxy chemistry involves the reaction of an aminoxy group with an aldehyde or ketone to form an oxime ether derivative

(Scheme 1.1). The aminoxy nitrogen exhibits very different properties from the nitrogen of an amine moiety. Table 1.1 highlights a few of these major differences.

Scheme 1.1. Reaction of an aminoxy with an aldehyde or ketone to form an oxime ether.

Table 1.1. Comparison of the aminoxy functionality with a primary amine.

The stark difference between the aminoxy group and the primary amine stems from the presence of the oxygen adjacent to the nitrogen (i.e., in an α -position), a phenomenon termed the α -effect.² Edwards and Pearson³ first introduced the α -effect in 1962 to explain the enhanced nucleophilicity of a certain group of nucleophiles. The presence of an electronegative atom with one or more unshared pairs of electrons in an α -

position to the nucleophilic atom was the one common feature among this class of nucleophiles. Edwards and Pearson postulated that the unshared electrons in the α -position help to stabilize a positive charge on the nucleophilic atom, thus allowing the nucleophilic atom to more freely bond to electrophiles.

A major contributing factor to the chemoselectivity of the aminoxy nitrogen is the electronegativity of the α -oxygen. This is most evident by observing the pK_a difference between a protonated aminoxy ($RONH_3^+$) having a pK_a of 5-6⁴ and a primary aminium (RNH_3^+) having a pK_a of 9-10. Hydrazine, another molecule/functional group subject to the α -effect, has a pK_a of 8 when protonated. Similar to an aminoxy group, hydrazine reacts with aldehydes and ketones to form stable hydrazones, but it is not chemoselective like the aminoxy group in that it will react with esters, phthalimides and anhydrides. The hydrolytic stability of oximes and hydrazones, in contrast with imines, is also due to the α -effect. As can be seen in Figure 1.2, the lone pair of electrons α to the sp^2 -hybridized nitrogen allow for resonance stabilization by increasing the negative charge density at C1, thus reducing its electrophilicity.⁵ When the resonance forms of an oxime or hydrazone are compared to the resonance forms of an imine it is easy to understand why imines are susceptible to hydrolysis. Imine electron density is primarily located at the nitrogen atom, making C1 electrophilic and prone to nucleophilic attack by water. In addition, Wiberg and Glaser⁶ proposed another explanation for the hydrolytic stability of oximes ethers and hydrazones. They predict that the reduction in lone-pair repulsion achieved by going from an aminoxy and hydrazine to respective oxime ether and hydrazone leads to this stability.

Oximes and Hydrazones

Imines

Figure 1.2. Resonance forms of oximes, hydrazones and imines. Resonance in oximes or hydrazones increases the negative charge density at C1 and imparts hydrolytic stability.

Though oximes and hydrazones are hydrolytically stable in an aqueous environment, hydrolysis can still be achieved. Figure 1.3 shows the mechanism of the acidic hydrolysis of oximes and hydrazones to restore the aminoxy and hydrazine along with the starting aldehyde. It is well known that the hydrazone bond is more susceptible to acidic hydrolysis than its oxime counterpart. As was noted by Kalia and Raines,⁵ the difference in hydrolytic stability is due to the electronegativity of the atom α to the nucleophilic atom in the preceding aminoxy or hydrazine (atom X, Figure 1.3). For the oxime, the increased electronegativity of an oxygen atom ($\chi_{\text{O}} = 3.5^7$) in the X position (Figure 1.3), α to the nitrogen, reduces the probability of the formation of **III** and increases the likelihood of forming **II**. This resonance makes the convenient hydrolysis of oxime ethers require heat with HCl or HClO₄ at pH 0-4. Hydrazones, due to the reduced electronegativity of a nitrogen atom ($\chi_{\text{N}} = 3.0$) in the X position (Figure 1.3), can undergo hydrolysis under more mildly acidic conditions. The hydrazone functionality

makes the formation of **III** much more likely, thus perpetuating the acidic hydrolysis to give the hydrazine and starting aldehyde.

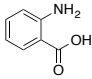

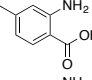

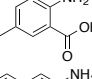

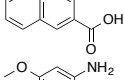

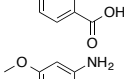

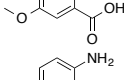

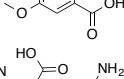

Figure 1.3. Mechanistic considerations for acid-induced hydrolysis of oximes and hydrazones.

The ability of the aminoxy functionality to chemoselectively bond to aldehydes and ketones to form oxime ethers makes it attractive for a variety of applications. Though aminoxy groups are usually quite reactive and can react to completion very rapidly, there are some oximation reactions that occur very slowly. Numerous different catalysts have been studied to hasten this process. Crisalli and Kool⁸ report a panel of anthranilic acids for the nucleophilic catalysis of oximation and hydrazone formation (Table 1.2). Aniline is the central focal point of the majority of nucleophilic catalysts for oximation and hydrazone formation.⁹ Aniline catalyzes the reaction by first forming an iminium ion, then the nucleophilic amine of an aminoxy or hydrazine functionality can

primary amine on an aldehyde or ketone under acidic conditions to form the susceptible iminium ion, can be compared to a reductive amination reaction.¹¹ The enhancement of oximation and hydrazone formation reactions under acidic conditions was displayed in Crisalli and Kool's⁸ catalytic studies, as can be seen in Table 1.3. It should also be emphasized that all reported catalysts for oximation and hydrazone formation reactions are water-soluble and the water solubility of the catalyst is oftentimes a deciding factor for its promise.¹²

1.2. CHEMOSELECTIVE LIGATION

Most organic chemistry transformations cannot be performed in aqueous conditions, thus making the application of organic chemistry techniques to biological systems, such as cells, challenging. Due to this difficulty, researchers interested in common biological processes, such as ligation, are constrained and forced to work with a limited number of reactions.¹³ Figure 1.4 shows the limited catalog of chemoselective reactions available for ligation or other modifications of cells. The hydrolytic stability, chemoselectivity and overall robustness of the aminoxy linkage make it an excellent candidate for such biological applications.

Figure 1.4. Chemoselective ligation reactions used in the convergent assembly of biopolymers and their mimetics, and in the modification of biopolymers and cells. The products of the reactions are (A) N-acylhydrazones, (B) oxime ethers, (C) thiosemicarbazones, (D) thioethers, (E) native amide bonds, (F) simple amide bonds, (G) pseudoproline linkages, (H) tetrahydro- β -carbroles, (I) native amide bonds after reduction of disulfide bonds, and (J) amide phosphine oxide.¹⁴

Pascal Dumy's lab has developed a tetrameric cRGD containing nano-probe by covalently linking four peptides to the cyclic decapeptide scaffold regioselectively addressable functionalized template (RAFT).¹⁵ Dumy *et al.* used aminoxy ligation to ensure chemoselectivity, versatility and allow for covalent attachment without the use of coupling agents. But the most influential reason that oximation was the chosen ligation technique was that the oxime bond afforded robust and stable linkages for both *in vitro* and *in vivo* applications. This technology, now commercially available under the name AngioLoneTM, can be linked with a fluorescent dye or with radioactive contrast agents for use in the surgical removal of tumors. The $\alpha_v\beta_3$ integrin is overexpressed on the surface of endothelial cells¹⁶ and several tumor cell types.¹⁷ RGD is a known recognition motif and thus allows the AngioLoneTM to have a high tumor-targeting efficacy.¹⁸ As a proof of concept for upcoming human clinical trials, Coll *et al.* applied AngioLoneTM for the removal of a mesenchymal tumor, a feline fibrosarcoma, where it was found to be effective in the accurate, safe and complete removal of the tumors in real surgical conditions. As can be seen in Figure 1.5, the cluster of $\alpha_v\beta_3$ ligands are bound to the decapeptide RAFT through oxime ether bonds.

Figure 1.5. Chemical structure of the tetraivalent RGD ligand RAFT conjugated to a fluorescent or radioactive label.¹⁹

Zeng *et al.*²⁰ used oxime ether and thioether linkages to build a synthetic lipopeptide-based self-adjuvanting vaccine that can elicit neutralizing antibodies against heat-stable enterotoxin from enterotoxigenic *Escherichia coli*. They found that the thioether vaccine showed residual toxicity in suckling mice while the oxime ether versions expressed no cytotoxicity. Though both the thioether and oxime ether vaccine produced specific anti-ST antibodies, only the oxime ether vaccine, specifically the ST^N-oxime-P2C-T_H vaccine, generated antibodies capable of neutralizing the virus when administered by the mucosal (intranasal) route. This finding suggests that the chemical linkage affects the efficacy of the antibodies. Figure 1.6 shows the three different vaccines that Zeng and coworkers synthesized.

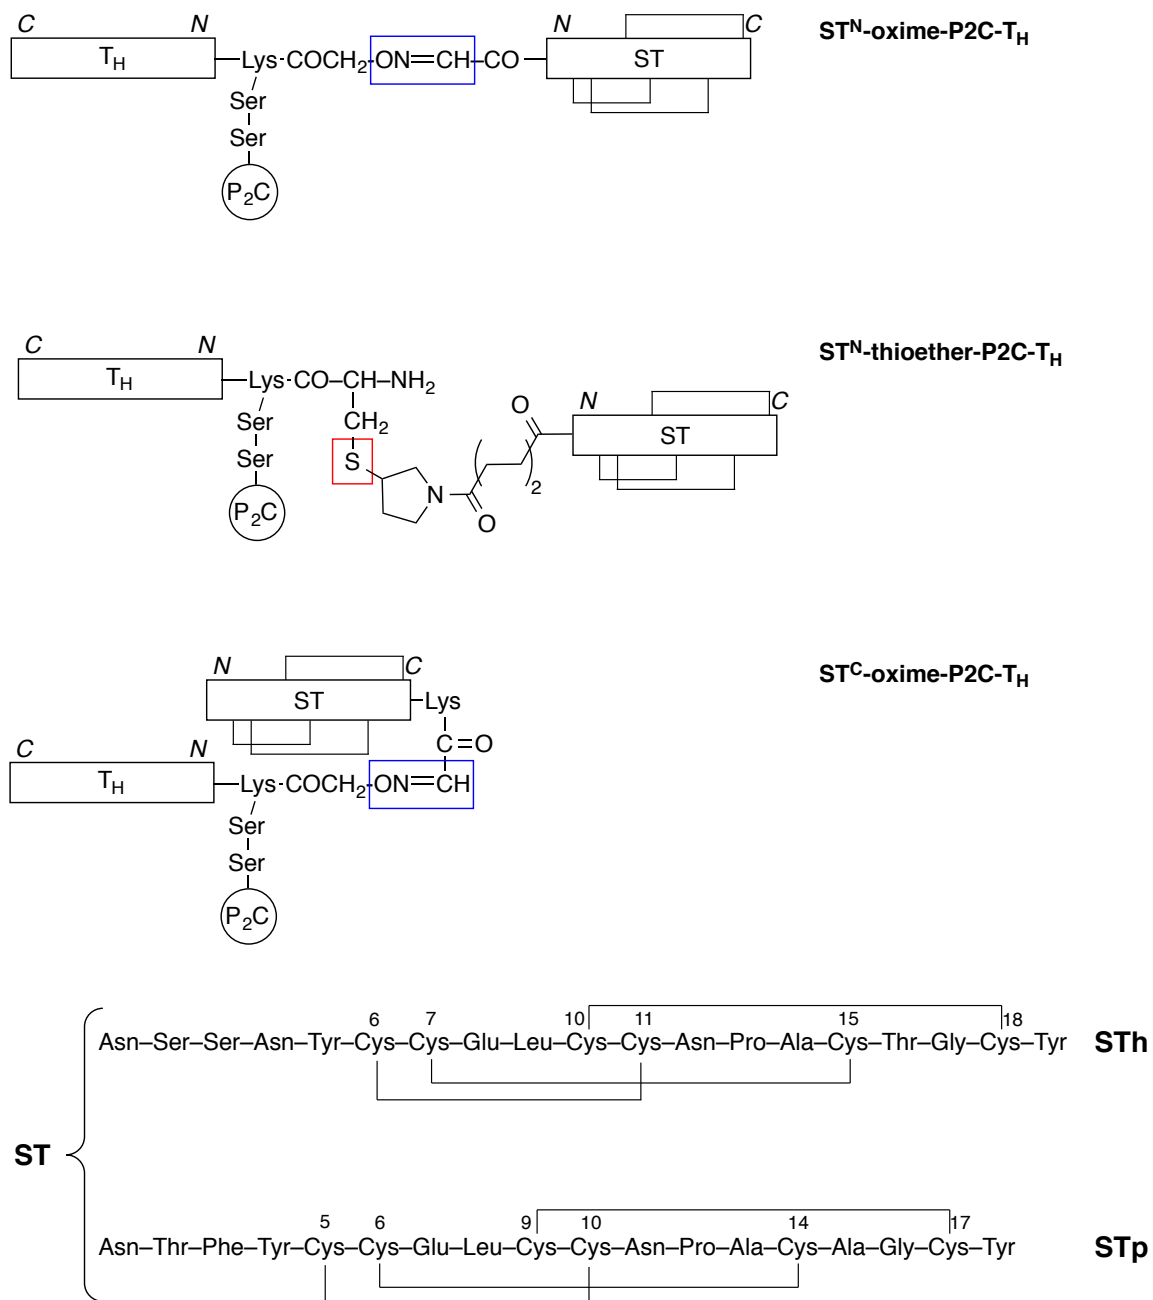

Figure 1.6. Schematic representation of the structures of the ST-based lipopeptide vaccines with oxime ether and thioether linkages. T_H refers to the helper T cell epitope, C and N refer to the *N*-terminus and *C*-terminus, respectively, of peptide sequences and P2C refers to *S*-[2,3-bis(palmitoyloxy)propyl]cysteine.²⁰

1.3. SOLID-SUPPORTED AMINOXY CHEMISTRY

Oxime bonds are also used extensively for solid support surface modification. Lepens *et al.*²¹ modified surface plasmon resonance (SPR) chips with aminoxy groups using a newly developed bifunctional linker. After the carboxylic acid groups on the SPR chip surface were activated with 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC) and *N*-hydroxysuccinimide (NHS), a solution of a Boc-protected aminoxy derivative was injected. To quench the unreacted activated esters on the SPR chip a solution of ethanolamine was injected. Following cleavage of the Boc protecting group, *N*-terminal aldehyde or ketone functionality was introduced either by oxidation of *N*-terminal amino acids with pyridoxal 5'-phosphate ($R = R' =$ amino acid side chain) or by oxidation of *N*-terminal serine ($R' = H, R'' = CH_2OH$) or threonine ($R' = H, R'' = CH(CH_3)OH$) residues using $NaIO_4$. These functional groups allowed for the covalent retention of the modified proteins on the SPR chip (Scheme 1.3). The process was catalyzed with aniline and, consistent with previously discussed findings, Lepens *et al.* found that the oximation reaction occurred most rapidly under acidic conditions at pH 4.5.

Scheme 1.3. Site-specific immobilization of peptides and proteins on a biosensor chip surface using aniline-catalyzed oximation.²¹

Another example of solid-supported aminoxy chemistry was shown by Chan *et al.*²² in a layer-by-layer approach to immobilize polymeric films onto glass. Glass substrates derivatized with aldehyde groups were dipped into a solution of aminoxy substituted poly(phenylenevinylene) (PPV) in methylene chloride and were allowed to sit for 4 hours. Sonication was used to remove unbound polymer. The coated plates could then be alternately immersed in aldehyde and aminoxy functionalized PVP to form the

multilayer films (Figure 1.7). This technology provided nanostructured thin films with potential in a range of applications from light-emitting diodes to the coating for biomedical devices.²³

Figure 1.7. Multilayer deposition of PPV supported aldehyde and aminoxy substrates on derivatized glass via chemoselective ligation.²²

1.4. USE OF AMINOXY CHEMISTRY IN NANOTECHNOLOGY

The click assembly of aminoxy compounds with aldehyde and ketone substrates has also been employed in the popular field of nanotechnology. Using gold nanoparticles (NPs), Thygesen *et al.*²⁴ synthesized glyconanoparticles from unprotected reducing glycans and glycopeptide aldehydes. To do this, a protected aminoxy-thiol linker was bound to a gold NP through a gold-thiol bond. Following deprotection, the active aminoxy was reacted with unmodified reducing glycans via a single chemoselective

reaction to attach them through an oxime ether bond to the surface of the gold NPs (Table 1.4). The oximation was performed in phosphate buffer solution (PBS) without catalysis and all of the glycans contained a fluorenylmethyloxycarbonyl (Fmoc) protecting group to allow for spectrophotometric quantification of the aminoxy NP capture efficiency (Scheme 1.4).

Scheme 1.4. Synthesis of aminoxy-terminated core-shell gold NPs via Trim deprotection and oximation of a peptide, glycopeptide and glycan. Trim quantification gave an aminoxy loading of ~ 435 reactive linkers/gold NP.²⁴

^a Calculated from Fmoc quantification relative to trimellitoyl (Trim) quantification.
^b By microwave heating.

Biswas and coworkers²⁵ used iron oxide, specifically Fe₃O₄, NPs as a solid support for quaternary ammonium lipids to serve as a magnetic transfection vector (Scheme 1.5). The ammonium salt allowed for electrostatic attraction between the negatively charged surface for the NPs and a cationic polar head group of the lipid. By using click ligation to attach the hydrophobic chain a variety of lipids could be easily bound to the NPs to aid in finding the most efficient lipid for transfection. In addition, the magnetic NPs allow for *in vivo* direction and collection of the coated NPs at the treatment site.

Scheme 1.5. Preparation of lipid-coated Fe₃O₄ NPs using oximation to attach hydrophobic chains.²⁵

Zhang *et al.*²⁶ used core-shell Fe₃O₄-SiO₂ NPs to covalently attach an aminoxy linker to the NP surface. Using alkoxy silane chemistry, a Boc-protected was bound to the NP surface followed by deprotection using trifluoroacetic acid (TFA) to unmask the reactive aminoxy (Scheme 1.6). Zhang and coworkers used the functionalized NPs to chemoselectively capture glycopeptides via oximation in the presence of non-oxidized peptides. This method is particularly attractive due to the magnetic properties of the iron oxide NPs. After the glycopeptides are covalently bound to the NPs, the loaded iron NPs

can be rapidly magnetically separated from the mixture.

Scheme 1.6. Installation of an aminoxy moiety onto core-shell Fe_3O_4 - SiO_2 NPs for subsequent chemoselective reaction with glycopeptides.²⁶

1.5. IRON OXIDE NANOPARTICLES

As is apparent from the aforementioned examples, iron oxide NPs can readily serve as an advantageous solid support. Iron oxide NPs are ferromagnetic in both the form of Fe_3O_4 or the more oxidized version Fe_2O_3 .²⁷ This magnetism allows the NPs to be easily removed from suspensions with the use of a magnet. The magnetism of the NPs also allows enables applications as magnetic resonance imaging (MRI) contrast agents.²⁸ In this capacity, the magnetic NPs greatly enhance the sensitivity of MRI, a technique that is often coupled with another imaging method, such as positron emission tomography (PET), to account for its low sensitivity. Huang *et al.*²⁹ have reported such a coupling of MRI using NPs with PET for increased sensitivity.

Localization within the body of the iron oxide NPs in the area of interest is an important part of effectively utilizing the magnetic NPs as a contrast agent. To achieve spatial and temporal orientation of NPs, surface functionalization is generally required.

Yang *et al.*³⁰ synthesized receptor-targeted NPs for *in vivo* imaging of breast cancer. The NP surface was functionalized with a peptide containing a fragment of a urokinase-type plasminogen activator (uPA) (Figure 1.8). The bound uPA ligand directed the NPs to uPA receptors that were overexpressed in breast cancer tissues. The benefit of using a magnetic NP-based contrast agent over a small molecule contrast agent is that the small molecule agents have a relatively short lifespan (< 30 minutes), thus resulting in degradation prior to accumulation at the tumor site.³¹ Polymer-coated iron oxide NP-based contrast agents have been shown to have over eight hours of plasma retention time.³² This helps to ensure that the NPs reach and bind to the tumor cells. Yang and coworkers³⁰ report that the NPs remained stable *in vivo* and in intracellular environments for over forty-eight hours during the imaging experiments. The Food and Drug Administration (FDA) have already approved use of iron oxide NPs as an MRI contrast agent due to biological compatibility and an agreeable toxicity profile.

Figure 1.8. Final functionalization of polymer-coated iron oxide NPs with an amine terminated fragment of urokinase-type plasminogen activator to enable binding of the NP to breast cancer cells, and cyanine 5.5 dye to aid in fluorescent imaging of the NP location.^{30, 33}

1.6. USE OF IRON OXIDE NANOPARTICLES TO GENERATE HEAT

One of the more novel ways to exploit the magnetic properties of iron oxide NPs is to use them as a source of heat. When the magnetic NPs are subjected to an alternating magnetic field (AMF) the NPs generate heat as they attempt to realign their magnetic pole with that of the AMF. The NPs transform the energy from the AMF into heat via

two mechanisms: 1) through internal dipole rotation or Néel relaxation, and 2) by physical particle rotation called Brownian relaxation as can be seen in Figure 1.9.²⁷ In either case, there are internal and external factors that prevent the magnetic dipole of the NP from realigning with the AMF, thus resulting in the production and release of heat. The dominant form of relaxation is largely thought to follow the mechanism with the shortest relaxation time. Small nanoparticles tend to be dominated by Néel relaxation while in larger particles the Brownian relaxation prevails.

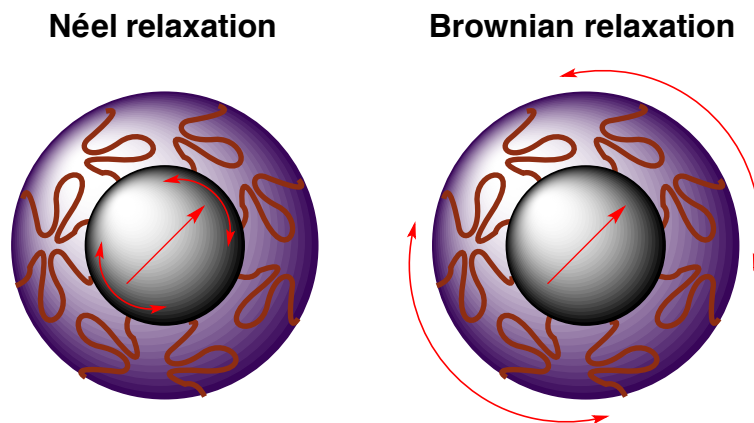

Figure 1.9. Magnetic NPs respond to AMF through either internal dipole rotation, Néel relaxation, or through physical particle rotation called Brownian relaxation. The straight arrow shows the alignment of the internal magnetic dipole and the arched arrows show whether the dipole or the NP is rotating.²⁷

When the iron oxide NPs are < 20 nm in diameter they can begin to be superparamagnetic.³⁴ Superparamagnetism is a form of magnetism where the magnetization can randomly flip direction under the influence of temperature.³⁵ The time between the reorientation of the magnetic dipole is the Néel relaxation. In the absence of

an external magnetic field the superparamagnetic particles appear to show no magnetism. This phenomenon is due to the time used to measure the reorientation of the magnetization being much longer than the Néel relaxation. The aforementioned attributes, in addition to other variations such as alteration of size,³⁶ shape³⁷ and functionality,³⁸ make iron oxide NPs an attractive solid support with tunable magnetic properties.

One application of AMF-induced iron oxide NP heating is localized hyperthermia for cancer abolition. Hyperthermia treatment first involves localization of iron oxide NPs (Fe_3O_4 or $\gamma\text{-Fe}_2\text{O}_3$) in a tumor and then AMF exposure to elevate the local, cellular temperature to at least 40-47 °C.³⁹ These elevated temperatures result in cell death. Alternate methods for inducing hyperthermia are based on the application of microwaves.⁴⁰ But the use of microwaves has been limited due to the inability to control temperatures and the ineptitude to minimize collateral damage such as exposure to radiation and a lack of selectiveness that causes extensive damage to the surrounding healthy tissue. Treatment of iron oxide NPs with an AMF also has the advantage of using an alternating current (AC) magnetic field with a significantly lower frequency (10^5 Hz) than its microwave counterpart at nearly 10^{15} Hz. Operation at a frequency of 10^5 Hz results in negligible damage to the living tissue. Figure 1.10 shows an MFH 300F® AMF applicator instrument (MagForce Nanotechnologies, AG, Berlin, Germany) that is currently being used to treat patients via hyperthermia.³⁹

Figure 1.10. Thermotherapy treatment of the pelvic region after intratumoral injection of magnetic NPs using the AMF applicator MFH 300F³⁹.

AMF-induced hyperthermia is also frequently used in conjunction with chemotherapy to increase the efficacy of an administered drug. This multimodal approach circumvents many of the limitations of conventional chemotherapy and hyperthermia. In chemotherapy, aggressive cytotoxic drugs kill both cancerous and healthy cells without discrimination and can cause systemic toxicity and decreased drug concentrations in the tumor.⁴¹ Hyperthermia suffers from insufficient temperature increase in the tumor, poor temperature distribution and risk of damage to surrounding organs due to overheating.⁴² Aoki *et al.*⁴³ reported a significant increase in drug efficacy when malignant gliomas were treated with liposomal adriamycin, a chemotherapeutic

drug, in addition to mild hyperthermia at 40 – 43 °C. Purushotham and Ramanujan⁴⁴ found that when doxorubicin (Dox) was loaded into poly-*n*-isopropylacrylamide coated iron oxide (12 nm diameter Fe₃O₄ or 23 nm diameter γ -Fe₂O₃) NPs the *in vitro* tumor cells were far more responsive to treatment when compared to *in vitro* tumor cells treated with only Dox or hyperthermia. The efficacy of Dox was increased enough that the therapeutic effect obtained with a normal dosing could be matched by using Dox/magnetic NPs with doses as low as 20% – 50% of the standard dosing. Using the combination of Dox and AMF-induced hyperthermia with magnetic NPs, Alexiou *et al.*⁴⁵ found that the same chemotherapeutic result could be obtained using a dose of as low as to 20% - 50% of the standard dosing of Dox.

1.7. CONCLUSION

It is clear from the above examples that aminoxy chemistry, and the resultant oxime ethers formed on chemoselective reaction of an aminoxy moiety with an aldehyde or ketone carbonyl, are of great value for biological applications. The aminoxy groups also provide the versatility to react readily in a variety of solvents, importantly water, while either in solution or bound to a solid support. Chapter 2 presents a solid-support application of a new aminoxy-based reagent, 4-(2-aminoxyethyl)-morpholin-4-ium chloride (AMAH). Relying on both electrostatic and hydrogen-bonding interactions, a silicon microreactor can be loaded with AMAH for chemoselective, covalent capture and concentration of volatile aldehydes and ketones in exhaled breath (Scheme 1.7). This application has great potential in the early diagnosis of lung cancer. AMAH-adducts can be analyzed via Fourier transform-ion cyclotron

resonance (FT-ICR) mass spectrometry (MS) as well as gas chromatography (GC) MS. By utilizing both forms of analysis, volatile organic compounds (VOCs) can be quantified and the conformational isomers, indistinguishable by FT-ICR-MS, can be accurately assigned. We developed a novel method to benefit from the cationic aminium salt using FT-ICR-MS while being able to neutralize the salt and directly inject the VOC adduct solution for GC-MS analysis without the use of salts or a liquid-liquid extraction.

Scheme 1.7. Chapter 2 Summary: AMAH oximation covalently traps aldehydes and ketones in the microreactor.

Chapter 3 describes the synthesis of a panel of thermally labile linkers engineered to undergo intramolecular cyclization on heating. One goal of this work is application to a polydimethylsiloxane microchannel (Figure 1.11) for use in combination with aminoxy chemistry to capture aldehyde and ketone metabolites passing through the microchannel. After preparing the linker panel, each substrate was analyzed to determine any thermal responsiveness. By design, heating is intended to promote addition of a nucleophilic amine, positioned along a connecting chain, to an electrophilic carbonyl to form various-sized heterocyclic rings. To tune the thermal responsiveness of the linker different functional groups including esters, amides, carbonates and carbamates were inserted

around the electrophilic carbonyl. We also tuned the cyclization rate by altering the ring size from five to seven and employing *gem*-dimethylation. After an optimal linker was established, we installed an aminoxy group and then bound the assembly to the interior walls of a microchannel for carbonyl capture applications.

Figure 1.11. Chapter 3 Summary: Heat-induced cyclization via (a) lactamization or (b) carbamate formation.

Chapter 4 describes our efforts to engineer an AMF-induced iron oxide NP drug delivery system, one that involves a covalently NP-bound drug as opposed to a NP-associated drug (Figure 1.12). This work possessed many hurdles including formation of a covalent bond between the iron oxide NP and the organic linker, modification of the surface properties of the NPs, reduction of NP agglomeration as well as the discovery of a phenomenon that had not yet been reported. Though originally expecting to utilize our thermally labile linkers for drug delivery, we discovered a not-yet-reported release mechanism that appears to be the result of an AMF-induced hydrolysis. We were able to

hydrolyze robust, *i.e.* carbonate and carbamate, functionalities at room temperature, neutral pH and in less than 45 minutes.

Figure 1.12. Chapter 4 Summary: AMF-triggered hydrolysis of pendant functionality (FL = fluorophore, •; carbamate moiety, n; terminal amine residue, n).

Chapter 5 presents the experimental procedures for all of the chemistry described in Chapters 2, 3 and 4. Select ^1H and ^{13}C NMR spectra as well as other select spectroscopic data of synthesized molecules and NPs are provided in Appendix A.

2.1. INTRODUCTION

In 2011, there were 98,000 men and 77,000 women who developed lung cancer.¹ Only ~18% of these people will survive beyond five years.¹ However, if the spread of the lung cancer can be minimized at the time of diagnosis and quickly treated, the five-year survival rate increases to 54%.¹ Thus, the early detection of lung cancer is of critical importance. Currently, the common methods of diagnosing lung cancer include, but are not limited to, bronchoscopy, PET scan or needle biopsy, all of which are after having completed a CT scan. All of these methods are either invasive or subject the patient to a substantial dose of radiation. Due to the aforementioned side effects, these methods of diagnosis are usually used only when the cancer has become symptomatic. Lung cancer is largely asymptomatic in its early stages. Screening is the only systematic means of finding tumors at the surgically curable stage.² Therefore, it is easy to appreciate the need for a non-invasive method to accurately diagnosis lung cancer in its early stages.

There are many minimally or non-invasive methods being designed and tested for clinical application in the early detection of lung cancer. Some of these methods include the cytology of the sputum,^{3,4} detection of circulating cancer biomarkers,^{5,6} determination of blood proteomic patterns,^{7,8} chest tomography,^{9,10} and whole body magnetic resonance imaging (wbMRI).¹¹ But all of these techniques suffer from serious drawbacks. Specifically, sputum cytology regularly provides false negatives and, therefore, fails to detect numerous early-stage cases of lung cancer.¹² Circulating cancer biomarkers, when used alone, have not shown promise as a screening test and it is not yet clear which panel of tests will afford the necessary sensitivity and specificity.^{13, 14} Blood proteomic patterns are difficult to establish, though FT-ICR has aided in the advancement of this

technology.^{5,6} Computed tomography (CT) scans, despite subjecting the patient to high doses of X-ray radiation, can accurately detect nodules as small as 1 mm in diameter, but they also show many false positives if not confirmed by positron emission tomography (PET), that lead to unnecessary biopsies.¹⁵ Table 2.1 outlines the different methods of analysis, the procedure for the collection of a sample, the invasiveness and the method of diagnosis of lung cancer.

Table 2.1. Analytical procedures for the diagnosis of lung cancer.

Method of Analysis	Collection of Sample	Invasive/ Non-Invasive	Method of Diagnosis
Cytology of the sputum	- Subject coughs up mucus	Non-Invasive (coughing)	Cells are observed under microscope to determine if abnormalities are carcinogenic
	- Subject inhales saline followed by coughing - Bronchoscopy	Invasive (bronchoscopy)	
Circulating tumor biomarkers	- Tissue collection - Draw blood	Invasive	Tissue biopsy/blood analysis looking for known cancer derived metabolites
Blood proteomic patterns	- Draw blood - Lung cancer tissue - Serum - Plasma - Pleural effusions	Invasive	MALDI-TOF or FT-ICR-MS used to scan for known proteins derived from cancer
Chest tomography	Spiral CT scan of chest	Non-Invasive	CT image shows visible nodules in lung
Whole body magnetic resonance imaging (wbMRI)	wbMRI	Non-Invasive	Used in partnership with diffusion weighted imaging (DWI) and apparent diffusion coefficient (ADC) to determine metabolic and morphological deviations

The analysis of volatile organic compounds (VOCs) in exhaled human breath is another area of focus for non-invasive early diagnosis of lung cancer. In 1971, Pauling *et al.*¹⁶ reported that human breath is comprised of over 1000 VOCs. Beginning in 1985, O'Neill and coworkers^{17, 18} identified 28 VOCs from exhaled breath as candidate markers of lung cancer, including hexane, methylpentane, *o*-toluidine, and aniline. In addition, altered lipid-peroxidation activity in patients with lung cancer was observed in the form of over-oxidized VOC metabolites.^{19, 20} But since most VOCs occur at picomolar concentrations, advanced techniques must be employed to effectively capture and concentrate the VOCs prior to analysis.²¹

The development of devices to perform the capture and subsequent concentration of the VOCs in exhaled breath has received much attention. One of the most simplistic (and sensational) methods of diagnosing lung cancer from exhaled breath involves the use of canines for scent detection. First proposed by Williams and Pembroke in 1989,²² the hypothesis for this method of detection is based on the idea that dogs are known to possess superior olfactory systems capable of detecting VOCs at parts-per-trillion levels from complex mixtures.²³ Application of five dogs (both genders) for canine scent detection in a double-blinded testing of 28 lung cancer patients and 6 breast cancer patients against 17 controls found that the dogs had an overall sensitivity of 0.99 (95% confidence) and overall specificity of 0.99 (95% confidence) when compared to biopsy-confirmed conventional diagnosis.² Despite the tremendous sensitivity and specificity of the dogs, there are significant drawbacks to this idea, largely due to the variables involved with a living species.

Other, more conventional, forms of non-invasive lung cancer diagnoses include the aforementioned induced sputum, exhaled nitric oxide, exhaled breath condensate and the electronic nose. The advantages and disadvantages of each non-invasive diagnostic method are summarized in Table 2.2. In particular, the electronic nose possesses great potential in its ability to accurately identify specific VOC profiles in exhaled breath. But the electronic nose is comprised of a series of electronic sensors of different composition and relies heavily on complex algorithms to give rise to the so-called “breathprint.”²⁴

Analysis of VOCs that are a direct result of the oxidative stress inherent in lung cancer, usually in the form of aldehydes and ketones, is another area that has great potential. Table 2.3 shows common targeted VOC metabolites along with the method of detection, concentration threshold and whether the technology has been tested with humans.

Table 2.2. Mean advantages and disadvantages of non-invasive diagnostic tools detecting biomarkers of pulmonary inflammation in smoking subjects.²⁴

Diagnostic Tools	Biomarkers	Advantages	Disadvantages	Conclusions
Induced Sputum	Airway cellularity Inflammatory mediators in supernatants	Easier and more comfortable than bronchoalveolar lavage or bronchial biopsy	Not completely non-invasive; may induce bronchospasm	Partially conflicting data; need large longitudinal studies
Exhaled Nitric Oxide	Nitric oxide in exhaled air	Completely non-invasive; repeatable	Many confounding factors such as meals, asthma, respiratory infections	May play an important role in smoking cessation programs
Exhaled Breath Condensate	Many inflammatory markers in exhaled air	Completely non-invasive; repeatable	Not standardized	Smokers show an increased oxidative stress and a lower pH than non-smokers
Electronic Nose	Able to identify specific VOC profiles in exhaled breath	Completely non-invasive; repeatable	Not standardized	Discriminate between healthy non-smokers and healthy smokers

2.2. AMAH: A VERSATILE REAGENT FOR ANALYSIS OF VOCS

Our attempt to develop a non-invasive method for early detection of lung cancer also focuses on the capture and identification of carbonyl metabolites. My group colleague, Dr. Souvik Biswas,⁵¹ had developed the reagent *N*-(2-(aminooxy)ethyl)-*N,N,N*-trimethylammonium iodide (ATM) to chemoselectively capture volatile aldehydes and ketones from exhaled human breath and ambient air.^{52, 53, 54, 55} Several carbonyl compounds in exhaled breath previously had been identified as lung cancer markers.^{52, 56, 57, 58, 59, 60, 61} Reaction of ATM with VOCs was achieved by first coating ATM on the surface of micropillars within a silicon microreactor. The microreactor (or, more precisely, a preconcentrator) contains thousands of micropillars that function to distribute gas flow through channels to provide surface area for efficient capture of the VOCs by the reactive coating. Aldehydes and ketones from exhaled breath are selectively and covalently preconcentrated in the microreactor using a click chemistry reaction (oximation). The resultant ATM-carbonyl adducts are eluted from the microreactor using a small volume (*ca.* 50 μ L) of methanol, and analysis of the breath analytes then is performed using rapid direct-infusion Fourier transform-ion cyclotron resonance (FT-ICR) mass spectrometry (MS) to determine the concentrations of exhaled carbonyl VOCs.

Though convenient for rapid identification of biomarkers, FT-ICR-MS is often incapable of distinguishing structural isomers (e.g., constitutional isomers), especially as compound molecular weights increase. One method for confirming an isomer assignment is to use gas chromatography-mass spectrometry (GC-MS) in conjunction with a reference standard of the compound. Unfortunately, the adducts of ATM are not

suitable for analysis by GC-MS since ATM is non-volatile as a consequence of its quaternary ammonium moiety. The use of ammonium ions to enhance the MS signal intensity at low concentrations is a well-established technique,⁶² but since such ions typically are non-volatile a new strategy is required to conjunctively use the speed and accuracy of FT-ICR-MS with the isomeric differentiation afforded by GC-MS. We developed an approach to address this challenge by introducing a versatile aminoxy reagent, 4-(2-aminoxyethyl)-morpholin-4-ium chloride (AMAH, Scheme 2.1). AMAH functions as a chemoselective probe as a consequence of the aminoxy reactivity, and it contains a titratable ammonium salt for enhancing [+] ion electrospray MS analysis. Moreover, AMAH-carbonyl adducts can be made volatile for analysis by GC using a straightforward basification procedure. By applying AMAH onto the micropillars of the silicon microreactor, the dual capability of AMAH can be exploited through detection and structural assignment of carbonyl VOC adducts from exhaled breath using both FT-ICR-MS and GC-MS.

Scheme 2.1. AMAH oximation covalently traps aldehydes and ketones in the microreactor.

2.3. RESULTS AND DISCUSSION

ATM was specifically designed with several features that would optimize analyses of its adducts by FT-ICR-MS. The quaternary ammonium salt allowed for electrostatic interaction between ATM and the negatively charged silica surface of the micropillars (Scheme 2.1). Secondly, the aminoxy moiety allowed for the rapid, chemoselective capture of gaseous aldehyde and ketone metabolites in exhaled breath samples with >90% capture efficiency.⁵⁵ Finally, the permanent positive charge of the quaternary ammonium salt enhanced the signal intensity of the metabolite adducts at low concentrations when analyzed by FT-ICR-MS.⁶² In addition to cost considerations, a limitation of analyzing ATM-adducts using FT-ICR-MS is the inability to differentiate constitutional isomers for a given molecular mass. MS-MS techniques can be applied to address this issue; however, use of a more widely available and affordable analytical platform, such as GC-MS, would improve the accessibility of the microreactor approach for identifying metabolites. Unfortunately, GC-MS cannot be used to analyze ATM-carbonyl metabolite adducts since these are non-volatile. To address this issue, we developed a second-generation reagent that allows for both FT-ICR-MS and GC-MS identification with isomeric accuracy.

Figure 2.1. Structures of ATM, AMAH and AMA.

By slightly expanding the structural framework of ATM, we engineered second-generation reagent, AMAH (Figure 2.1), that features a titratable aminium nitrogen instead of a quaternary ammonium salt. The morpholino bridge, as opposed to *N,N*-dimethyl, imparts an order of magnitude greater acidity for ease of basification, a subsequent key step, to generate neutral species, such as AMA or neutral AMA-carbonyl adducts.⁶³ Upon introduction to the microreactor, the aminium salt of AMAH electrostatically bonds to the silica surface of the micropillars while the morpholino oxygen and aminic proton also provide hydrogen bonding opportunities with surface silanols to improve the availability of the aminooxy moiety for carbonyl capture. Finally, the tertiary ammonium ion also enhances the MS signal intensity for analyses using FT-ICR-MS so that high mass accuracy can be determined for even low abundance carbonyl metabolites.

The key advantage in using AMAH over ATM for metabolite identification is its ability to be volatilized through a basification procedure, thus making it applicable for both FT-ICR-MS and GC-MS analyses. To ensure that the basification of AMAH-carbonyl adducts proceeds to give an analyte mixture that can be injected directly into a GC instrument, we developed a salt-free neutralization procedure that does not require liquid-liquid extraction or other lengthy handling processes (Scheme 2.2). First, the eluted methanolic AMAH-carbonyl adduct mixture can be directly analyzed by FT-ICR-MS. An aliquot can then be prepared for GC-MS analysis by reaction with poly(4-vinylpyridine) (PVP), an acid scavenging polymer (Figure 2.2). We were gratified to

Figure 2.2. Structure of poly(4-vinylpyridine) (PVP).

find that when a 40 μL sample of AMAH-adducts in methanol was added to 2 mg of PVP followed by shaking for 30 seconds, complete neutralization of the adducts was achieved. Efficient neutralization using this procedure was confirmed by NMR spectroscopy (Figure 2.3). When the acetone- d_6 adduct of AMAH is treated with PVP, the chemical shifts of the morpholino methylene protons coalesce into broad singlets, at δ 3.95 and δ 3.37 ppm for the methylene signals adjacent to oxygen and nitrogen, respectively, as a result of the greater conformational flexibility of the AMA-adduct. This procedure is particularly appealing in that after basification using PVP the polymer quickly sediments to allow convenient aliquot sampling for direct GC injection.

Scheme 2.2. Use of AMAH for both FT-ICR-MS and GC-MS analyses. PVP = poly(4-vinylpyridine)

Figure 2.3. 400 MHz ^1H NMR (CD_3OD) of (a) AMAH-acetone- d_6 adduct and (b) AMA-acetone- d_6 after treatment with PVP.

To examine the reactivity of AMAH with volatile carbonyl compounds, we performed a calibration experiment with acetaldehyde, acetone and 2-butanone in a closed chip. Each carbonyl (7.67×10^{-7} to 7.67×10^{-10} mol) was injected into a 1 liter Tedlar bag and connected to the preconcentration setup (Figure 2.4). A vacuum pump

Figure 2.4. Schematic flow diagram of the preconcentration set-up.

pulled the gaseous contents of the bag through the AMAH-functionalized, closed microreactor (Figure 2.5) at a rate of 3.5 mL/min. After the Tedlar bag had been fully evacuated, the microreactor was removed from the preconcentration assembly and the analytes were washed free from the chip using methanol. A solution of AMAH-

Figure 2.5. Silicon microreactor for the capture of carbonyl VOCs in exhaled breath. (a) Optical micrograph of the microreactor before bonding with a glass wafer. (b) SEM micrograph of the micropillar array within the microreactor.

acetone- d_6 adduct was added to the analyte solution to serve as an internal standard. For both aldehydes and ketones, the linear capture efficiency of AMAH peaks at a ~91 % capture rate at a 10^3 AMAH/analytes molar ratio (Figure 2.6, Table 2.4). The reason that the highest capture efficiency occurred at higher AMAH/analyte molar ratios is due to the elevated reaction probability for the capture of aldehyde and ketone VOCs. Due to the low concentrations of carbonyl VOCs in exhaled breath, 180-800 ppbv for acetone, AMAH should capture nearly all of VOCs of interest and provide an accurate concentration of each metabolite.^{64, 65} Having confirmed that AMAH was highly reactive

Figure 2.6. Graphical relationship between VOC capture efficiency and AMAH/VOC molar ratio.

Table 2.4. Tabulated relationship between VOC capture efficiency and AMAH/VOC molar ratio.

AMAH/VOC molar ratio	log(AMAH/VOC molar ratio)	Capture Efficiency (% ± standard error)

1000	3	89.3 ± 3.6	92.4 ± 2.9	91.1 ± 1.6

and applicable for both FT-ICR-MS and GC-MS, we analyzed a panel of AMA-C₁-C₅ aldehyde and ketone adducts (Figure 2.7, Table 2.5) on GC-MS to establish reference retention times for the adducts.

Figure 2.7. GC-MS chromatogram of reference AMA–carbonyl adducts; TBSO = *t*-butyldimethylsilyloxy.

Table 2.5. Retention times of AMA–C₁–C₇ adducts.

Adduct	<i>t_R</i> (min)	Adduct	<i>t_R</i> (min)

^a TBSO = *t*-butyldimethylsilyloxy

Following calibration, the closed chip was replaced by an open chip to allow a patient to blow directly onto the AMAH-functionalized microreactor through a straw. Subjects blew into a vial containing the microreactor for 15 minutes. Upon completion, methanol was used to elute the AMAH-adducts from the microreactor, and the collected eluent then was directly analyzed by FT-ICR-MS. Figure 2.8 shows a FT-ICR-MS spectrum of a healthy non-smoking subject. An aliquot (*ca.* 35 μL) of the methanol AMAH-adduct mixture also was added to PVP. After neutralization, the PVP was

Figure 2.8. Qualitative comparison of (a) FT-ICR-MS spectrum and (b) GC-MS chromatogram of VOCs from a healthy, non-smoking subject.

filtered and the methanol filtrate was evaporated. To the residue was added a 1:1 mixture of acetonitrile:*N-tert*-butyldimethylsilyl-*N*-methyltrifluoroacetamide (MTBSTFA) (v/v) (30 μ L). MTBSTFA was used to produce volatile and stable *tert*-butyldimethylsilyl (TBS) derivatives of hydroxyl groups for GC analysis. MTBSTFA was used over TBSCl because its reaction byproducts are volatile and neutral, thus minimizing the risk of degrading other VOCs. The resultant silylated AMA-adduct mixture was analyzed by GC-MS. With results from both the FT-ICR-MS and GC-MS analyses in hand, we compared the abundance of captured carbonyls by calculating the ratio of the abundance of an analyte to the sum of the abundance of all analytes (Table 2.6). The results indicate that the carbonyl ratios based on GC-MS analysis were consistent with the ratios calculated using the FT-ICR-MS results with a 2.6% variance as the largest difference (entry 1).

Table 2.6. Quantitative comparison of FT-ICR-MS and GC-MS analyses of a breath sample.^a

Entry	Carbonyl VOC	GC-MS ^b	FT-ICR-MS ^b
1	CH ₂ O (formaldehyde)	0.128	0.154

^a Breath sample from a healthy, non-smoker;

^b Analyte contribution to total (ratio of analyte abundance/sum of the abundance of all analytes).

With the knowledge that AMAH can be used in conjunction with either GC-MS or FT-ICR-MS to analyze these high abundance carbonyl compounds in exhaled breath, Dr Fu working with Dr. Michael Bousamra, University of Louisville, Brown Cancer Center, examined samples from more than 30 non-smoker controls, 30 smoker controls and 50 patients diagnosed with lung cancer to determine differences in their exhaled breath. Each subject blew into a vial containing an AMAH-functionalized open chip for 15 minutes. Then, the AMAH-adducts were washed from the microreactor with methanol and injected for FT-ICR MS analysis (Figure 2.9a). Finally, an aliquot was neutralized, silylated and then analyzed by GC-MS. Figure 2.9a shows typical FT-ICR-MS spectra of a non-smoker control, a smoker control and a lung cancer patient. Figure 2.9b shows typical GC-MS chromatograms of a non-smoker control, a smoker control and a lung cancer patient.

Figure 2.9. Analyses of a healthy non-smoker control, smoker control and lung cancer subject via (a) FT-ICR-MS and (b) GC-MS.

The FT-ICR-MS and GC-MS spectra both show that the smoker control and the lung cancer subject have considerably more carbonyl VOCs than the non-smoker control. For example, *n*-propanal and 2-pentanone are conspicuous in the lung cancer subject. Figure 2.8a and 2.8b also show a higher abundance of 2-butanone and *n*-pentanal in the exhaled breath of the lung cancer patient. These compounds have been reported as lung cancer markers.^{52, 57, 58, 60} Hydroxyacetaldehyde and 3-hydroxy-2-butanone also have been identified as lung cancer markers in our previous work on closed chip microreactors.⁵² Whereas breath analysis for detection of lung cancer using GC-MS has great potential, these results are only a preliminary indication of the potential of AMAH. In this regard, a major advantage in using AMAH/AMA is the ability to accurately determine marker molecular formulae as well as to detect the isomeric differences by GC-MS that FT-ICR-MS does not provide. For example, 2-pentanone and pentanal are constitutional isomers that would register as a single *m/z* on FT-ICR-MS, but the AMA adducts of these VOCs are readily separated by GC-MS to reveal an abundance of one over the other. In addition, due to the chemoselectivity of aminoxy compounds for reacting with aldehydes and ketones,⁶⁶ interference of other abundant volatiles in exhaled human breath, such as O₂, CO₂, H₂O and numerous VOCs, is avoided and this greatly facilitates carbonyl compound calibration as well as peak identification.

2.4. CONCLUSION

This thesis research resulted in the development of a second-generation ammonium aminoxy probe, AMAH, to efficiently capture trace aldehyde and ketone VOCs from exhaled breath when applied to a silicon microreactor containing thousands of

micropillars. The AMAH-coated microreactor chemoselectively and covalently concentrates carbonyl VOCs through an oximation reaction. The resultant AMAH-adducts can be readily rinsed from the microreactor by elution with cold methanol and then directly analyzed by FT-ICR-MS. The positive charge of the AMAH-VOC adducts enhances sensitivity for the high mass accuracy and ultra-high resolution of FT-ICR-MS to enable determination of molecular formulae. Also developed was a protocol whereby the AMAH-VOC adduct solution is added to a small amount of the acid-scavenging polymer PVP to produce volatile AMA-VOC adducts that can be analyzed by GC-MS. This versatile attribute of AMAH enables the identification and quantification of isomeric metabolites using GC-MS. The combination of a titratable aminium reagent with the PVP neutralization protocol constitutes a general approach that may be applicable for the development of other chemoselective probes.

2.5. FUTURE DIRECTIONS

To expand the use of this technology, I have also synthesized ADMH, an aminium version of ATM, as can be seen in Figure 2.10. The synthesis of ADMH was similar to that of ATM. A Mitsunobu reaction with *N,N*-dimethylethanolamine was performed to afford the phthalimide protected aminoxy. The phthalimide was cleaved via hydrazinolysis with methylhydrazine and the resulting ADM was distilled using a

Figure 2.10. Structures of ATM and ADMH.

Kügelrohr apparatus. Due to the reactive nature of the aminoxy terminus, the ^1H NMR spectrum revealed that *ca.* 48% of the product had reacted and formed an oxime ether adduct. To circumvent this problem, the partially reacted material was hydrolyzed under acidic conditions (6 M HCl, reflux, 22 h) to unmask the aminoxy moiety and to provide the ADMH amminic proton needed to reduce volatility. The reactivity of ADMH and its application to both FT-ICR-MS and GC-MS analyses are currently being investigated by Dr. Xiao-An Fu and collaborators.

In addition, I have pursued initial efforts to prepare an aminoxy reagent that could be used for the analysis and detection of VOC adducts via HPLC-MS. Our goal in designing this molecule was to have a non-volatile aminoxy molecule that was sufficiently reactive to efficiently capture and covalently retain VOCs from exhaled breath while also providing a convenient and sensitive method of detection, such as by HPLC. We chose to use a fluorescent detector with the HPLC to ensure that we would be able to quantify the VOC oxime ether adducts at nanomolar concentrations. When searching for a fluorophore, we found a paper by Goto *et al.*⁶⁷ that specifically addressed the formation of sensitive fluorescence labeling reagents for HPLC of carbonyl compounds. Figure 2.11 shows a time course to exemplify the oximation of **2** with a ketone (*ca.* 12 α -hydroxy-3-oxo-5 β -chloanoic acid). Though Goto only reported the reactivity of **2**, he noted that there was no difference in the reactivity between the anthracene-aminoxy molecules.

Figure 2.11. Time course for derivatization of 12 α -hydroxy-3-oxo-5 β -chloanoic acid with *O*-(2-anthrylmethyl)hydroxylamine (**2**).⁶⁷

With this information in-hand, we synthesized AAn (Figure 2.11) from 9-anthracenemethanol. Briefly, the alcohol was reacted with *N*-hydroxyphthalimide under Mitsunobu conditions to afford the phthalimide-protected aminoxy that was deprotected with hydrazine monohydrate to give AAn. Though initial results are encouraging, the Fu lab is still in the early stages of testing AAn and comparing its reactivity with ATM and AMAH.

CHAPTER 3

THERMALLY-INDUCED INTRAMOLECULAR CYCLIZATION AS A MECHANISM FOR SUBSTRATE RELEASE

- 3.6. CONCLUSION

-

3.1. INTRODUCTION

Intramolecular cyclization is a well known chemical process often exploited in synthesis, not only for target molecule synthesis but also for diverse applications in many fields, such as materials science and biochemistry. Examples include carbon-carbon bond formation via intramolecular Diels-Alder reactions¹ as well as catalyzed cyclizations² and formation of heterocyclic rings such as lactones,³ lactams,⁴ and oxazolidinones.⁵ Though intramolecular cyclization is usually utilized as a means to ring formation, it can also be used as a mode of substrate release. The intramolecular cyclizations that focused more so on substrate release typically were engineered in this manner to function as mechanisms for drug delivery.^{6,7,8,9} In these cases, the released substrate is either a phenol ($R' = Ar$) or an aniline derivative (Figure 3.1b) so that the intramolecular cyclization occurs rapidly at physiological temperature,¹⁰ generally with a half-life from minutes to one hour.¹¹ Intramolecular cyclizations of this type also have been used to unmask aromatic hydroxyl,¹² amine¹³ or thiol¹⁴ moieties as mechanisms to initiate electron cascade reactions or for release of polymer-bound drugs (Figure 3.1).¹⁵ Again the focus was to use the intramolecular cyclization for rapid drug release at physiological temperature, and this required R' to be aromatic. Few examples have used this approach to release non-aromatic alcohols,^{16,17} the most common being for the delivery of 5-halo deoxyuridine analogs.^{18,19,20}

Figure 3.1. General structure of drug or prodrug delivery systems involving (a) electron cascade reactions, (b) rapid intramolecular cyclizations or (c) a hybrid of intramolecular cyclization and electron cascade reactions.¹¹

Our interest in control over heat-induced intramolecular cyclization as a mechanism for substrate release led us to investigate linkers that would expel HO-R' (Figure 3.2) at temperatures above 37 °C, such as in response to an externally triggered local hyperthermia. In addition to the release of alcoholic substrates, thermally induced intramolecular cyclization could also be used to release any carbonyl agent by fitting R' with an aminoxy group.

Figure 3.2. Heat-induced cyclization via (a) lactamization or (b) carbamate formation.

3.2. FIRST GENERATION

My first generation attempts at developing this strategy were motivated by a report published in *Organometallics* by Ojima and Vidal²¹ that described the synthesis and reactivity of amine **1** (Figure 3.3). We envisioned that the hydroxyl group could readily be transformed into the requisite, electrophilic carbonyl needed for the cyclization trigger, as in **2** (Figure 3.3). Aside from this attribute, **2** would also afford an alkoxy silane group that could allow the linker to be covalently bound to a variety of solid supports containing surface hydroxyl groups.^{22, 23} Finally, the intramolecular cyclization could occur in response to heat. Thermal induction was desired because the cyclization rate could be tuned to occur at a range of temperatures, allowing for the technology to be adjusted for the application. In order to tune the thermal responsiveness of **2**, the butyl group could be modified to increase or decrease steric bulk. In addition, the primary alcohol of **1** would allow the subsequent carbonyl to be an ester or a carbonate. This

functional group variation from ester to carbonate would allow for accelerated or retarded cyclization, respectively.

Figure 3.3. Proposed alterations to molecule published by Ojima and Vidal.²¹ The target molecule would cyclize when heated to form the lactam.

Scheme 3.1. Synthesis of **2**. Conditions: *a*. Phthalimide, DIAD, PPh₃, THF, 0 °C, 87%; *b*. N₂H₄•H₂O, CH₂Cl₂, 56%; *c*. *n*-BuLi, chlorodimethylsilane, THF, -78 °C, 73%; *d*. cat. Rh₄(CO)₁₂, CO (10 atm), toluene, 60 °C; *e*. NaBH₄, MeOH, toluene, 66% over 2 steps; *f*. [O]; *g*. Substrate-OH; *h*. cat. Pd/C, H₂, MeOH.

Starting with 3-octyn-1-ol (Scheme 3.1), a two-step functional group transformation using Mitsunobu conditions to add a phthalimide followed by hydrazinolysis yielded oct-3-yn-1-amine in 49% overall yield. The primary amine was then bis-silylated by reaction with chlorodimethylsilane. Subsequent Rh₄(CO)₁₂-catalyzed intramolecular silylformylation of the resident alkyne moiety under 10 atm CO followed by immediate reaction with methanolic NaBH₄ afforded the stable azasilacyclopentane **5** in good yield. The results of the reaction were supported by the downfield position of the methylene protons and carbon of **1** (Figure 3.4) that was added in the reaction of CO with the alkyne bond. Further verification was found in the ¹³C NMR spectrum with carbon 2 and 3

(Figure 3.4) in the olefinic region. The presence of the *exo*-alkylene group of **5** is postulated to stabilize the Si–N bond against hydrolysis. This unique stability would allow for further modification of **5** while affording the ability to restore the characteristic hydrolytic susceptibility of Si–N bonds by subsequent hydrogenation. On hydrogenation of the exomethylene (and thus removal of its stabilizing influence) in dry methanol, the Si–N bond would be expected to immediately hydrolyze and form the target methoxysilane (e.g., as in **2**, Figure 3.3).

Figure 3.4. ^1H and ^{13}C NMR spectra (CDCl_3) confirming the synthesis of **5** (Scheme 3.1).

Despite our synthetic success, we ceased our pursuits of **2** after obtaining **5** due to concerns about the synthetic pathway. The first challenge was the hydrolytic susceptibility of **4** and the second concern was the safety of using CO gas at 10 atm of pressure at elevated temperatures. Throughout this process the scalability of our

syntheses was always a goal; therefore, a new target molecule was deemed necessary due to the finesse and potential dangers associated with the aforementioned concerns.

3.3. SECOND GENERATION

To create a less cumbersome synthetic approach while still maintaining the goal for development of a thermally induced intramolecular cyclization we reflected on the positive and negative aspects of the route involving **2**. On doing so, the linearity of the amine with the carbonyl became evident and made us realize that an ω -amino acid could be used as a readily available starting material (Figure 3.5).

Figure 3.5. Retrosynthetic analysis of **2** reveals a path for simplification involving an ω -amino acid starting material.

In addition to availability, there were other advantages to modifying the synthetic procedure to start with an ω -amino acid. First, the distance between the nucleophilic amine and electrophilic carbonyl was no longer fixed at four carbons. This is of great importance because it allows for tuning the thermal responsiveness by adjusting the size of the heterocyclic ring that would be formed, from an expected rapid 5-membered ring formation to a slower forming 7-membered ring. Second, an oxidation step to form the carbonyl was no longer necessary.

But there were also new synthetic challenges in using an ω -amino acid starting material. First, we would have to devise a way to incorporate an alkoxy silane into the linker. The second challenge was that the preexisting carbonyl was only advantageous for esterification. In order to modify the functionality around the carbonyl we would have to reduce the esterified or acidic carboxyl group to form a primary alcohol. The alcohol could then be used in the formation of a carbonate or undergo a functional group transformation to an amine for eventual carbamate formation (Scheme 3.2).

Scheme 3.2. Modification of carbonyl functionality from carboxylic acid to a carbonate or carbamate.

The first issue that we addressed was the incorporation of an alkoxy silane into the linker motif. A convenient location for attachment of an alkoxy silane group is to use the amine. In doing so, we gain nucleophilicity by forming a secondary amine. Furthermore, this approach would not be expected to deter the desired intramolecular cyclization — steric hindrance issues are minimal. We therefore decided to alkylate the primary amine with an allyl group to subsequently use the unsaturation as a means for incorporating the alkoxy silane through hydrosilylation methodology. Following a report by Sabourault *et*

*al.*²⁴ we used PtO₂ as a catalyst to add triethoxysilane in the γ position. As can be seen from the ¹H NMR spectrum in Figure 3.6, the disappearance of the olefinic peaks (red), the collapse of the methylenes surrounding the Boc-protected nitrogen into one broad peak (blue) and the appearance of an upfield peak at 0.57 ppm (green) all support the effectiveness of the hydrosilylation. Despite the option of other hydrosilylation catalysts (Table 3.1), PtO₂ was an affordable option that would enable us to use a minimal amount due to its high w/w percentage of Pt. In addition, the catalyst could be recovered and reused, thus making PtO₂ applicable for industrial reactions.

Figure 3.6. ¹H NMR spectrum (CDCl₃) of the hydrosilylated ester **14.3**.

4	PtO ₂ (83.69% Pt w/w)	24	> 95/5	> 95

^a Calculated on the basis of ¹H NMR spectrum.

We now turned our attention to studying how the functionality around the carbonyl and the heterocyclic ring size affected the rate of cyclization. To do this, we prepared a panel of amino carbonyl substrates to determine factors that would minimize the rate of cyclization at 37 °C while allowing cyclization to proceed at higher temperature (Figure 3.6).

3.3.1. Cyclization Panel (Figure 3.7)

All substrates were prepared to contain an *N*-allyl moiety for convenient functionalization, such as hydrosilylation or thiol incorporation, for eventual covalent attachment to various supports. To quantify release of the ‘payload’ (e.g., HO-R’ in **6-8** and **10-11**, H₂N-R’ in **9**) on heating, R’ was selected as a 9-substituted anthracene for ease of UV and fluorescent measurements. When using the commercially available 9-anthracenemethanol, we found that the acidic Boc-deprotection step would also

hydrolyze the fluorophore. This issue was circumvented by synthesizing the homologous 2-(9-anthracenyl)ethanol. In addition to the cyclization ring size (*italics*, Figure 3.6), we

Figure 3.7. Cyclization precursors (R = 2-(9-anthracenyl)ethyl). Ring size after intramolecular cyclization given in parentheses.

varied the carbonyl functionality to include ester, carbonate, carbamate and amide examples. The influence of *gem*-dimethylation, as in seven-membered ring precursors ester **10** and carbonate **11**, also was examined as a means to enhance intramolecular cyclization via the Thorpe-Ingold effect.²⁵

3.3.2. Syntheses (Schemes 3.3-3.7)

N-allylation²⁶ of commercial Boc-protected amino acids **12** followed by carbodiimide-mediated esterification with 2-(9-anthracenyl)ethanol²⁷ and Boc-deprotection furnished amino esters **6.1-3** (Figure 3.8, Scheme 3.3).

Figure 3.8. ^1H NMR (CDCl_3) of ester **14.3** showing successful Boc-protection, *N*-allylation and esterification with 2-(9-anthracenyl)ethanol.

Condensation of amino acid **13.1** with 2-(9-anthracenyl)ethanamine²⁸ gave the amino amide substrate **9**. In similar fashion, *N*-allylation of Boc-protected alcohols **15** (Scheme 3.4), after necessary silylation and desilylation steps, gave alcohols **16**. The carbonate moiety was installed by first forming the corresponding acyl imidazole intermediates **17**. Reaction with anthracenyl ethanol under basic conditions²¹ then gave amino carbonates **7.1-2**. Though the ^1H NMR spectra were similar for these compounds, the ^{13}C NMR spectra allowed for confirmation of the functionality around the carbonyl (Figure 3.9).

The *gem*-dimethyl amino ester **10** was prepared by applying the above-described three-step sequence of *N*-allylation, esterification and Boc-deprotection to commercially available amino acid **20** (Scheme 3.6). Synthesis of *gem*-dimethyl amino carbonate **11** followed from bis- α -methylation¹⁵ of the ester derived from amino acid **16.1** (Scheme 3.7). Mono-methylation could be identified by thin layer chromatography (TLC) since the R_f of bis- α -methylated product was 0.53 and the mono- α -methylated product had an R_f of 0.50. Incomplete α -methylation could also be confirmed by the integration of the ¹H NMR spectrum (Figure 3.10). Subsequent chemoselective ester reduction²⁹ and carbonate formation using the established method gave desired substrate **11**.

3.4. CYCLIZATION STUDY

To determine the release rates of the 9-substituted anthracenes (e.g., **25**, Scheme 3.8) from the panel of amino-carbonyl substrates, dilute methanol solutions of each compound were heated at 55 °C. Aliquots taken at various times were analyzed by normal phase HPLC for the appearance of **25** or **26**. Amino-carbamate **8** and amino-amide **9** were unreactive under the conditions and did not release detectable **25** or **26**, respectively (Scheme 3.8). As could be expected, anthracene alcohol **25** was released from the amino-ester and amino-carbonate progenitors of the 5- and 6-membered lactams (**24**, Y = CH₂, n = 0, 1) and oxazolidinones (**24**, Y = O, n = 0, 1) at rates faster than from the progenitors of corresponding 7-membered rings (Figure 3.11 and Table 3.2). Control experiments indicated that ester or carbonate methanolysis did not occur under the conditions to yield **25**. Whereas dilute conditions were used to reduce the incidence of

intermolecular reactions, these cannot be ruled out as a possible source of **25** particularly with the substrates that lead to 7-membered rings. In regards to potential heat-triggered release applications, the high thermal responsiveness of esters **6.1-2** and carbonates **7.1-2** make these constructs ideal for applications involving thermally sensitive substrates, such as in cell studies involving triggered release at or below 37 °C.

In contrast, the resistance to cyclization of the 7-ring progenitor ester **6.3** is promising for higher temperature applications (Figure 3.11 and Table 3.2), although the overall release of **25** from **6.3** on heating at 55 °C was low. Comparison of amino-esters **6.3** and **10** shows that *gem*-dimethylation more than doubled the heat-induced release of anthracene **25** after heating 24 h. The *gem*-dimethyl amino-carbonate **11** provided an even higher thermal response than *gem*-dimethyl ester **10** with a nearly 40% release of payload at 55 °C over 24 h. Furthermore, the *gem*-dimethyl 7-ring carbonate motif resists cyclization at lower temperatures. Incubation of **11** at 37 °C for 24 h resulted in only 5.7% ± 0.7% release of **25**.

We also performed an NMR experiment to prove that the release **25** was due to intramolecular cyclization and not intermolecular polymerization. ¹H NMR spectra allowed us to not only see **25**, but also the subsequent lactam or oxazolidinone. Samples of **6.1** and **7.1** were placed into NMR tubes with toluene-d₈ and heated. The resulting ¹H NMR spectra (Figure 3.12) showed the formation of cyclized rings that were in agreement with literature while also showing the liberated alcohol **25**.³¹ No polymerization was observed in the spectra.

Figure 3.12. ¹H NMR (toluene-d₆) spectra of ester **6.1** before heating (top spectrum) and after thermally-induced intramolecular cyclization (bottom spectrum).

3.5. MICROCHANNEL APPLICATION

With these cyclization trends established, we set out to incorporate an aminoxy group into the linker chain. We felt that the addition of an aminoxy group would allow us to design a pre-concentrator for the chemoselective capture of carbonyl metabolites from an aqueous solution. After concentration of the aldehydes and ketones, the oxime ether adducts would be released from the linker with mild heating.

We chose to use a poly(dimethylsiloxane) (PDMS) microchannel (Figure 3.13) as a substrate from which we could covalently attach our linker and release its cargo upon heating. Microchannels fabricated using PDMS have shown great utility for molecular and cellular separations due to their extremely high surface to volume ratio.³²

Figure 3.13. Schematic of poly(dimethylsiloxane) microchannel.

Further, small PDMS channel heights and incorporation of features, such as microfabricated grooves, enhance fluid mixing within the channel to increase interactions of functionalized surfaces with target molecules flowing through the channel.³³

The *N*-allyl moiety of ammonium aminoxy ester **27** (Scheme 3.9), based on the ester motif of **6.2**, was hydrosilylated²⁴ to attach a terminal triethoxysilane group. The ammonium aminoxy substructure of ester **27** follows from our previously published

work on ammonium aminoxy reagents for capture of aldehyde and ketone metabolites from aqueous cell extracts.^{34, 35} Subsequent condensation^{36, 37} with the PDMS microchannel (Figure 3.13) covalently attached **28** to afford an aminoxy-functionalized microchannel specific for reaction with aldehydes and ketones. Injection of an

Scheme 3.9. Poly(dimethylsiloxane) microchannel functionalization and heat-induced release study (FL = fluorescein, $\text{X}^- = \text{CF}_3\text{CO}_2^-$).

acetonitrile solution containing a fluorescent aldehyde probe, FITC (fluorescein isothiocyanate) reacted with a 4-aminobutanol equivalent (Scheme 3.10),³⁸ anchored the fluorophore to the surfaces of the microchannel via oxime ether formation. The

Scheme 3.10. Preparation of the aldehydic FITC moiety. Conditions:
a. H₂N-(CH₂)₃-CH(OEt)₂, 94%; *b.* 30% aq. AcOH, 50%.³⁸

quaternary ammonium salt of **28** ensures availability of the aminoxy moiety for reaction with aldehydes since charged polar groups are repelled by the hydrophobic PDMS matrix. The capture and covalent attachment of the FITC-derived fluorophore to the microchannel was verified using fluorescent microscopy (Figure 3.14a). Boc-deprotection using trifluoroacetic acid afforded trifluoroacetate salt **30**. Concerned that loss of captured aldehyde probe may occur at this stage, we verified that no fluorescent probe was released prior to neutralization and thermal triggering. Indeed, no fluorescence was observed in the microchannel effluent after heating **30** at 60 °C for 30 min. Injection of a dilute solution of triethanolamine into the microchannel neutralized the linker. After subsequent rinsing (CH₃CN) of the microchannel, we were gratified to observe that mild heating (60 °C, 30 min) promoted the intramolecular cyclization to release alcohol **32**. As can be seen in Figure 3.14b, nearly complete release of the bound

fluorophore was achieved. Further utilization of this release mechanism in microchannel studies of cell metabolites requiring hydroxide-free cleavage conditions are ongoing.

Figure 3.14. Fluorescence microscopy image of (a) FITC-derived substrate **17** within the microchannel and (b) same field of view showing microchannel fluorescence after heating neutralized **18**.

3.6. CONCLUSION

In summary, a brief study on the cyclization of amino esters and amino carbonates as a mode for substrate release revealed that both ring size and carbonyl functionality significantly influence the release rate. The process is facile at mild temperatures in cases where 5- and 6-membered rings are formed, even for non-phenolic alcohols as illustrated in a PDMS microchannel application. In contrast, an amino carbonate motif leading to a seven-membered ring appears well suited for applications requiring thermal

stability at 37 °C while still releasing the alcohol substrate at slightly elevated temperatures. This particular secondary amine–carbonate structural combination may be a promising linker for drug delivery vehicles relying on the generation of local hyperthermia.

4.1. INTRODUCTION

An important attribute of a drug delivery system is regulated spatial and temporal drug release to minimize side effects as well as to improve the therapeutic efficacy of conventional pharmaceuticals. Iron oxide nanoparticles (NPs) possess many appropriate qualities that make them a viable choice for drug delivery formulations. Magnetite (Fe_3O_4) NPs are biocompatible,¹ have low cytotoxicity,² and provide multiple means for surface modification. Fe_3O_4 NPs are set apart from other forms of iron oxide due to inherent paramagnetic or superparamagnetic properties.³ As a result of the magnetism, one highly-studied feature of Fe_3O_4 NPs is their ability to heat a surrounding environment when exposed to an alternating magnetic field (AMF). Indeed, irradiation of Fe_3O_4 NPs with an AMF to cause local hyperthermia (i.e., to raise target body tissue to 40-45 °C) is an emerging alternative treatment for several cancers,⁴ such as melanoma,^{5, 6} glioblastoma,^{7, 8} liver,^{9, 10} or prostate^{11, 12} cancer. Furthermore, when the Fe_3O_4 NPs are fitted with a drug, attached either through ionic interactions or via entrapment in a polymer gel coating, the drug may be guided to tumors using a magnet, a property first demonstrated by Meyers in 1963.¹³ Consequently, many Fe_3O_4 NP-based systems now are extensively functionalized for drug delivery applications.^{14, 15}

Some of the most common approaches for association of drug payloads with Fe_3O_4 NPs include encapsulation of Fe_3O_4 NPs within drug-loaded liposomal formulations,^{16, 17} addition and subsequent functionalization of mesoporous silica shells^{18, 19, 20} and the use of polymer coatings to surround the Fe_3O_4 NPs (Figure 4.1).^{21, 22} As the NPs reach

Figure 4.1. (a) Liposomal, (b) mesoporous silica and (c) polymeric iron oxide drug delivery platforms that use AMF-induced heat as a mechanism for controlled drug release.

a target (e.g., cancerous) tissue, a release mechanism is initiated so that the drug payloads are available only to the target tissue. The most popular release mechanisms

include the use of pH-sensitive — typically acid-labile — triggers (Figure 4.2a),²³ photolabile linkers (Figure 4.2b)²⁴ and AMF irradiation (Figure 4.1).^{25, 26}

Figure 4.2. Drug release mechanism for (a) acid-labile hydrazone linkages and (b) photolabile *o*-nitrobenzyl linkages.

AMF-induced drug release has a distinct advantage over the pH-mediated approaches in that the former exploits advantages associated with using a controllable, *external* stimulus whereas the latter requires contact with an *internal* stimulus that cannot be easily controlled. AMF induction stimulates controlled release at a specific region and at a specific time without the need for a precise, and often unpredictable, internal environment.^{27, 28} Despite the advantage of controlled release using an AMF trigger, many such NP drug delivery systems still have a problem with premature drug release (i.e., payload leaching). In these instances, drugs are continuously released prior to application of the external stimulus.^{29, 30} This problem is generally due to the inability of the payload to be covalently retained until the stimulus is applied. For example, Brule *et al.*³¹ have used AMF-induction to increase the porosity of drug-loaded, alginate microbeads containing Fe₃O₄ NPs. Whereas this elegant approach is quite functional for

drug release, undesired diffusion of loaded drug from the microbeads is noted prior to AMF irradiation. Thus, the development of an AMF-responsive delivery system that covalently retains its payload until stimulated would constitute a desirable next-step and advance the evolution of nano-delivery systems.

4.2. NANOPARTICLE FUNCTIONALIZATION AND RELEASE

4.2.1. Initial Loading

Our initial concept was to covalently tether a drug to an Fe_3O_4 NP via a thermally labile functionality using a linking chain that contains a secondary amine, such as shown by NP assembly **1** (Figure 4.3). With judicious choice in linker length, we expected that application of an AMF to raise the surrounding temperature would power an intramolecular cyclization via reaction of the amine with the carbonyl moiety, as in [2]. We aimed to achieve this goal using one of our thermally labile linkers (Figure 4.4) discussed in Chapter 3.

Figure 4.3. AMF-mediated intramolecular cyclization results in release of ROH. X = CH_2 , O, NH, or NR' .

Figure 4.4. Cyclization precursors ($R = 2$ -(9-anthracenyl)ethyl). Ring size after intramolecular cyclization given in parentheses.

The first issue that we addressed was the formation of a covalent bond between Fe_3O_4 NPs and an organic linker. Despite the plethora of options for non-covalent bonding of Fe_3O_4 NPs, including but not limited to catechols,³² polysaccharides,³³ liposomal,³⁴ polymers³⁵ and cationic molecules,³⁶ there are limited options to effectively form a covalent bond to iron oxides. The three avenues to the formation of a covalent bond to Fe_3O_4 NPs (Figure 4.5) are 1) phosphonic acids/phosphonates³⁷ 2) trichlorosilanes³⁸ and 3) alkoxy silanes.^{39,40} Out of these three, only the trichlorosilanes and the alkoxy silanes form a true covalent bond. It has been suggested that the phosphonic acids and phosphonates, similar to carboxylic acids, bind to the iron oxide surface through an interaction with a trivalent iron atom.⁴¹ The resulting interaction between the Fe_3O_4 and the carboxylic acid is relatively weak while the phosphonic acids and phosphonates form stronger interactions.⁴² The chlorosilanes, though quite effective

at forming bonds to the Fe₃O₄ NP surface, are quite hydrolytically unstable and are more difficult to handle when compared to the alkoxy silane. Due to the aforementioned reasons, the alkoxy silane is currently the primary method used to form a covalent bond to iron oxides. But formation of the Fe–O–Si bond is not as straightforward as the formation of the Si–O–Si bonds described in Chapter 3 between the linker and the PDMS microchannel. In Figure 4.6 Gelest, an industry leader in silanes and silicones, reports that the bonding effectiveness of an alkoxy silane with iron oxides is moderate. All Metal–O–Si bonds are inferior to the robust and hydrolytically stable Si–O–Si bonds.⁴³

Figure 4.5. Phosphonic acid/phosphonate, chlorosilane and alkoxy silane functionalities used to form moderate to strong bonds to Fe₃O₄ NPs.

Figure 4.6. Effectiveness of silane bonding to various substrates.⁴⁴

Using the same hydrosilylation protocol as described by Sabourault,⁷⁵ we added a triethoxysilane to linker **4.3** to allow for loading onto Fe₃O₄ NPs. The NP loading was achieved following a procedure by Ma *et al.*⁴⁵ to afford the functionalized iron oxide NPs. There were two different means of loading alkoxy-silylated molecules onto iron oxide NPs in literature. The two routes differ only after magnetically separating the NPs with the first route calling to dry the functionalized NPs under vacuum and the second route calling for the NPs to be dried by heating at ~100 °C (Figure 4.7, final bond formation/condensation step). The route described by Ma and coworkers called for the use of vacuum without heating. Abstaining from heating the NPs was attractive to us

since our NPs were functionalized with a thermally labile linker. Since we wanted to induce the intramolecular cyclization using AMF, not conventional heat, using vacuum to induce the final condensation reaction was desirable.

Figure 4.7. Hydrolytic deposition of silanes.⁴⁶

The Fe₃O₄ NPs that were used for the loading were synthesized using the Massart method as described by Mikhaylova *et al.*⁴⁷ and had an average diameter of 10 nm. The

NPs were synthesized by combining $\text{FeCl}_2 \cdot 4 \text{H}_2\text{O}$ and $\text{FeCl}_3 \cdot 6 \text{H}_2\text{O}$ in a 1:2 molar ratio in a 0.1 M solution of NaOH with rapid stirring. As the solution of the iron salts is added to the basic solution the black Fe_3O_4 NPs form.

To functionalize the magnetic NPs, they were suspended by sonication in ethanol with a small amount of water added to aid in hydrolysis of the alkoxy silane to form the silanol. The alkoxy silane linker was added to the NP suspension and was mechanically stirred for 24 h at room temperature. The functionalized NPs were magnetically separated and washed with EtOH until there was no activity to ultraviolet (UV) light observed in the supernatant as determined using thin layer chromatography (TLC). Finally, the NPs were dried under vacuum for 12 hours to afford a tan powder. Using the weight difference between the starting, black Fe_3O_4 NPs and the final, tan functionalized NPs, we had obtained a loading of $1.75 \mu\text{mol}/\text{mg}$. To verify that the linker was loaded onto the NPs and was still capable of undergoing an intramolecular cyclization to release, a portion of the NPs were suspended in toluene and heated to reflux for 22 hours. After magnetic separation, the supernatant was analyzed by TLC. TLC analysis (developed using UV and *p*-anisaldehyde stain) revealed the presence of 2-(9-anthracenyl)ethanol. This result confirmed that our linker was covalently bound to the Fe_3O_4 NP and was still capable of undergoing an intramolecular cyclization for the release of an alcohol.

When we began to characterize the functionalized NPs by attenuated total reflectance (ATR) Fourier Transform (FT) infrared (IR) spectrometry we noticed that our signal intensity was high and that we had an intense signal at 1060 cm^{-1} . This signal is attributed to Si–O, Si–O–Si and Fe–O–Si vibrations.⁴⁸ In addition, Galeotti and coworkers report that the signal intensity of the Fe–O bonds ($580\text{--}635 \text{ cm}^{-1}$) in a

monolayer of silane should be stronger than the Si–O, Si–O–Si and Fe–O–Si vibration signal. As can be seen in Figure 4.8 our peak at 1060 cm^{-1} is very intense and the peak at 632 cm^{-1} is much weaker.

Figure 4.8. FT-IR spectrum of Fe_3O_4 NPs functionalized via an EtOH:H₂O route with linker **4.3** obtained using ATR.

These results were indicative of a thick silica-linker shell around the iron oxide NP. These results were not desired despite the advantages provided by the silica shell including the robust Si–O–Si linkages between the linkers. We were targeting a silane monolayer for two main reasons, 1) to maximize the percent released when compared to the loading and 2) to increase the magnetism and thus the potential thermal response with the application of an AMF. Larumbe *et al.*⁴⁹ reported that as the thickness of the SiO_2 layer increases there is a sharp reduction in the magnetic response of the Fe_3O_4 NPs when

compared to analogous uncoated Fe_3O_4 NPs. After running the kinetic experiment, we knew that the 7-membered ring formation required temperatures above 55 °C and, therefore, were trying to maximize the AMF-induced release of thermal energy.

Before we could correct the thickness of the alkoxy silane coating we had to understand why the alkoxy silane was polymerizing instead of only binding to the surface of the NP. In order to form a SiO_2 shell on an Fe_3O_4 NP it is common to use the Stöber process, which is also performed in a solution of EtOH and water.⁵⁰ But this process utilizes basic conditions to catalyze the hydrolysis of the alkoxy silane and the condensation of the silanols. Following the LaMer model, the nucleation is the fast process and the particle growth follows without further nucleation and can also be thought of as the addition of monomers.⁵¹ In our case, the base was likely from excess NaOH that had not been removed from the synthesized Fe_3O_4 NPs. The presence of the base, in conjunction with the solvent conditions, had mimicked the Stöber process. Even if we were to eliminate the base from the prepared NPs, there was still worry that the water would eliminate our ability to positively obtain only a monolayer due to the inability to control the self-polymerization of the silanols in the presence of water as depicted in Figure 4.9.

Figure 4.9. Examples of hydrolysis and condensation of alkoxy silanes with surface hydroxyl groups in the presence of water to afford A) a monolayer, B) a bilayer and C) an uncontrolled and disorderly polymeric shell.

For greater reliability, we switched from using in-house prepared Fe_3O_4 NPs to commercial Fe_3O_4 NPs with a diameter of 20-30 nm (US Research Nanomaterials, 98+%). This change reduced the risk of any problems arising from having used more basic NPs — commercial NPs are acid-washed. We also averted the unpredictability of aqueous loading by shifting to an anhydrous variation. Galeotti *et al.*⁴⁸ reported a route

that would consistently provide a monolayer by performing the loading in chloroform instead of aqueous EtOH. The loading procedure involved suspending the Fe₃O₄ NPs in chloroform via sonication, then adding a solution of the alkoxy silane linker in chloroform to the suspension with sonication. Upon completion of the addition, the reaction was moved to an overhead stirrer and heated to 65 °C for at least 24 hours. Heat can be used instead of water to induce the hydrolysis of the alkoxy silane.⁴⁴ The work-up was consistent with Ma *et al.*⁴⁵ except the EtOH washes were replaced with chloroform washes. When the NPs functionalized via the procedure described by Galeotti and coworkers⁴⁸ were characterized by FT-IR, the spectra were similar to published data (Figure 4.10).

Figure 4.10. FT-IR spectrum of Fe₃O₄ NPs functionalized via an anhydrous route with linker **4.3** obtained using ATR.

4.2.2. Formation of Covalent Bond to NP

Now, with functionalized NPs similar to those published in the literature, we were able to begin experimenting with the exposure of the NPs to an AMF. We placed ~4 mg of the magnetic NPs functionalized with linker **4.3** in 0.75 mL of 2:1 phosphate buffer solution (PBS) : acetonitrile. The pH was adjusted to 7.4 with glacial acetic acid and the acetonitrile was used to keep the hydrophobic anthracene fluorophore in solution to enable fluorescence measurements to be taken. As a control, one vial was allowed to sit on the bench at room temperature and a second vial was subjected to an AMF at 595 amps and 204 kHz using a 5-turn coil. After separating the NPs by magnetic sedimentation, the supernatant could be conveniently analyzed. We were pleased to find that after 30 minutes of AMF exposure there was substantial fluorescence in the supernatant. However, much to our surprise, a similar result was obtained when analyzing the non-AMF exposed control (Figure 4.11).

Figure 4.11. 595 Amp AMF and non-AMF induced release of fluorophore from ~4 mg of 20-30 nm Fe₃O₄ NPs functionalized with linker **4.3** in 2:1 PBS:MeCN at pH 7.4.

There were two possibilities to explain the minimal difference between non-AMF and AMF-induced release. The first possibility was that the intramolecular cyclization was occurring at a faster than expected rate when attached to the iron oxide NP. The second explanation was that we were not actually forming a covalent bond to the magnetic NPs. This would be the case if we had not successfully initiated the final condensation in the NP loading (Figure 4.12).

Figure 4.12. Possible explanations for non-AMF induced release of fluorophore. A) accelerated intramolecular cyclization or B) linker anchored to NPs through a non-covalent, hydrogen bond.

To discriminate these theories, I synthesized linker **10** (Figure 4.13) wherein the secondary amine involved in the intramolecular cyclization is replaced with a non-reactive methylene group. Also, the anthracenyl fluorophore was slightly modified to use the commercially available 9-anthracenemethanol instead of the 2-(9-anthracenyl)ethanol since no Boc-deprotection step is required for synthesis of **10**. Having eliminated the possibility of an intramolecular cyclization for release of fluorophore, we expected it would be straightforward to differentiate this mechanism from the hypothesis that fluorophore release occurs via mere detachment of a hydrogen bound linker.

Figure 4.13. Linker **4.3**, capable of intramolecular cyclization, and **10** with a methylene instead of a nucleophilic amine, rendering it incapable of intramolecular cyclization. Linker **10** was used to probe the origin of the observed non-AMF induced release.

Using the procedure described by Galeotti *et al.*⁴⁸ the Fe₃O₄ NPs were functionalized with **10** in the same manner as the NPs were loaded with **4.3**. The AMF experiment was repeated with ~3 mg of Fe₃O₄ NPs coated with **10** and the addition of a 30 second sonication step to ensure that we would see fluorescence from any non-covalently bound fluorophore. The results of this experiment are shown in Figure 4.14. Though the non-AMF induced release without sonication has been reduced, sonication and AMF exposure resulted in substantial release of the fluorophore. These results led us to understand that we were not successfully initiating the final condensation step using vacuum in the absence of heat.

Figure 4.14. 595 Amp AMF and non-AMF induced release of fluorophore from ~3 mg of 20-30 nm Fe₃O₄ NPs functionalized with linker **10** in 2:1 PBS:MeCN at pH 7.4.

Dr. Jerry Larson, senior research fellow at Gelest Inc., Morrisville, PA, advised us that, despite what literature reports claim, Fe–O–Si bonds are difficult to form and that high temperatures (≥ 100 °C) are required to induce the final condensation reaction for covalent attachment of the linker to the iron oxide NP. Armed with this knowledge, the NPs that were functionalized with **10** were heated to 110 °C for 24 hours at atmospheric pressure and the previous experiment was repeated, the results of which are combined with the results from Figure 4.14 and shown in Figure 4.15. When compared with the results obtained using conditions 1a-3a, conditions 1b-3b showed almost no release of the fluorophore; a vast improvement in the minimization of undesired fluorophore release. These results also show that the use of heat to initiate the final condensation reaction and covalently bond the linker to the NP surface (Figure 4.7) is necessary and that vacuum

alone cannot form the Fe–O–Si bond. Without the use of heat, the hydrolyzed alkoxy silane is only hydrogen bound to the Fe–OH surface of the NP, thus explaining the high release rate when the functionalized NPs are subjected to sonication (condition 2a).

Figure 4.15. 595 Amp AMF and non-AMF induced release of fluorophore from ~3 mg of 20-30 nm Fe₃O₄ NPs functionalized with linker **10** in 2:1 PBS:MeCN at pH 7.4. With and without heat refers to the curing process of the functionalized NPs. Without heat NPs were cured under vacuum and with heat NPs were cured at 110 °C for 24 hour at atmospheric pressure.

Though the results presented in Figure 4.15 were promising, it was necessary to confirm that the anthracene fluorophore was still attached to the Fe₃O₄ NPs. The NPs loaded with **10** and cured at 110 °C (~3 mg) underwent saponification to liberate the esterified 9-anthracenemethanol. Briefly, bare Fe₃O₄ NPs (as a control) and NPs

functionalized with **10** were suspended in a 2:1 solution of THF:MeOH. Then, a 0.03 M aqueous solution of NaOH was added and the suspension was stirred overnight. After centrifuging the NPs out of solution the fluorescence of the supernatant was measured to find a fluorescent signal released only from the functionalized NPs.

4.2.3. Acidic Boc-deprotection on NPs

Since exposure of the NPs functionalized with the thermally labile linker to high temperatures were now required, we were no longer able to perform the acidic -C(O)Ot-Bu (Boc) deprotection prior to loading the linker onto the NPs. To test the acidic stability of the Fe₃O₄ NP and the Fe–O–Si bonds we synthesized a small linker, **11**, and attached it to the Fe₃O₄ NPs to form **12** (Scheme 4.1). We chose a secondary amine to best model our thermally responsive linkers.

Scheme 4.1. Boc-deprotection of a 2° amine bound to a 20-30 nm Fe₃O₄ NP under acidic conditions. Conditions: *a.* (EtO)₃SiH, cat. PtO₂, 90 °C; *b.* Fe₃O₄, CHCl₃, 65 °C; *c.* i. CF₃CO₂H : CH₂Cl₂, 1:1, 0 °C, 1 h; ii. Et₃N : CH₂Cl₂, 1:1, rt.

The Boc-deprotection of **12** was performed using 1:1 CF₃COOH:CH₂Cl₂ at 0 °C for 1 hour, the same as the Boc-deprotection performed to the linkers not bound to NPs. Upon completion the aminium functionalized NPs were magnetically separated, washed

with CH₂Cl₂ and dried under vacuum. Thermogravimetric analysis (TGA) of **12** and **13i** showed that ~50% of the loading had been cleaved during the Boc-deprotection. As an affirmation of the successful deprotection and presence of nucleophilic **13**, the NPs were neutralized with 1:1 Et₃N:CH₂Cl₂ and fluorescein isothiocyanate (FITC) was added. **13**, now functionalized with an FITC-thiourea fluorophore, was washed with methanol and ethyl ether, dried under vacuum and the fluorescent signal was observed using a Molecular Devices SpectraMax M5 fluorescent well plate reader. A well plate reader was necessary since the solid NPs prohibit the standard fluorescent emission at 90° to the excitation. The fluorescent signal confirmed the successful Boc-deprotection as can be seen in Figure 4.16, though costing ~50% of the loading. Since we were still aiming for proof of concept this was deemed acceptable.

Figure 4.16. Fluorescent signal of **13** functionalized with FITC via a thiourea linkage in MeCN.

We were now ready to load **14** (Scheme 4.2) onto the Fe₃O₄ NPs using the information we had learned. This included the information that anhydrous loading

conditions decreased the uncontrolled polymerization and loading of the NPs, heat was necessary to initiate the final condensation reaction and acidic Boc-deprotection could effectively be performed on NP-bound linkers. The release experiment was set-up similar to earlier experiments with **16** (~7 mg) being suspended in 2:1 PBS:acetonitrile (1.5 mL) at pH 7.4. First, **16** was suspended and left on the bench for 30 minutes without exposure to sonication or an AMF. Using magnetic separation **16** was removed and the supernatant was collected and retained for fluorescent measurements. Then, the samples of **16** were again suspended in 1.5 mL 2:1 PBS:acetonitrile and were subjected to an AMF at 595 amps and 204 kHz with a 5-turn coil for 30 minutes. The NPs were then magnetically separated and the supernatant was collected. Both samples of the supernatant were then analyzed using fluorescent spectrometry, the results of which are displayed in Figure 4.17. The only mystery that remained was an explanation for the continued release in the absence of an AMF.

Scheme 4.2. Loading of **14** onto 20-30 nm Fe₃O₄ NPs and Boc-deprotection of **15** under acidic conditions to afford a thermally labile linker. Conditions: *a*. (EtO)₃SiH, cat. PtO₂, 90 °C; *b*. Fe₃O₄, CHCl₃, 65 °C; *c*. i. CF₃CO₂H : CH₂Cl₂, 1:1, 0 °C, 1 h; ii. Et₃N : CH₂Cl₂, 1:1, rt.

Figure 4.17. 595 Amp AMF and non-AMF induced release of fluorophore from ~7 mg of **16** in 1.5 mL 2:1 PBS:MeCN at pH 7.4. The AMF-induced release is the result of what remained on the NPs following the incubation period of 30 minutes at room temperature in 1.5 mL 2:1 PBS:MeCN at pH 7.4.

4.2.4. AMF vs. Non-AMF Induced Release: Hydrolysis

We began to suspect that the hydrolytic susceptibility of the ester functionality might be the culprit responsible for non-triggered release of fluorophore. To test this theory we synthesized three short linkers, one with an ester functionality, one with a more hydrolytically stable carbonate functionality and one with an even more hydrolytically stable carbamate functionality (Scheme 4.3). The chemical structure of **17.1-3** was confirmed by ^{13}C NMR (Figure 4.18). Aside from the differences in the carbonyl carbon peak, the methylenes α to the carbonyl functionality also distinctly different chemical

shifts. The ester methylenes have a chemical shift of 64.3 ppm and 33.8 ppm with the methylene α to the carbonyl being upfield of the methylene adjacent to the ester oxygen. The allyl methylene of the carbonate was at 67.4 ppm, upfield of the methylene next to the oxygen on the anthracene side of the molecule that was at 68.7 ppm. The methylene beside the carbamate nitrogen had an upfield chemical shift of 43.7 ppm compared to the methylene near the oxygen, which had a chemical shift of 64.9 ppm. In addition to increasing the robustness of the carbonyl functionality, we also made several experimental adjustments: (1) the AMF power amperage was reduced from 595 amps to 200 amps (the frequency was kept at 204 kHz since the coil diameter and number of turns dictate this frequency); (2) to begin modeling physiological conditions, we changed the control conditions from NPs incubated at room temperature to NPs incubated at 37 °C; and (3) we also changed the AMF application protocol from 30 minutes of continuous exposure to a pulsed application of AMF consisting of consecutive 5 minute ‘on’ and 5 minute ‘off’ cycles for a total of 30 minutes of AMF exposure. The pulsed modification in the experimental design allowed for collection of multiple data points needed to establish a release profile and provided a procedure that would be more agreeable with a biological system. Figure 4.19 shows the results of the AMF experiments.

Scheme 4.3. Short chain linkers bound to Fe₃O₄ NPs to test hydrolytic stability of ester, carbonate and carbamate functionalities. Conditions: *a.* (EtO)₃SiH, cat. PtO₂, 90 °C; *b.* Fe₃O₄, CHCl₃, 65 °C.

Figure 4.18. ^{13}C NMR spectra (CDCl_3) confirming the structures of 17.1-3.

Figure 4.19. 200 amp AMF induced release of fluorophore from ~6 mg of **18.1-3** in 0.75 mL 2:1 PBS:MeCN at pH 7.4.

The release results from **18.1-3** were quite unexpected. The ester, the most easily hydrolyzed functionality of the panel, showed the lowest rate of release while the more robust linkages, carbonate and carbamate, showed higher release rates with the carbonate releasing the fastest. But the release patterns all appeared to be a stepwise release, indicating that it could be a result of AMF exposure. To test this theory we performed another experiment, but instead of exposing the NPs **18.1-3** to an AMF we incubated them at 37 °C in the 2:1 PBS:acetonitrile solution at pH 7.4 for 20 hours. This experiment would allow us to see if the release was AMF-induced. Figure 4.20 depicts the incubation results.

Figure 4.20. Release of fluorophore from ~6 mg of **18.1-3** in 0.75 mL 2:1 PBS:MeCN at pH 7.4 incubated at 37 °C for 20 h.

Incubation of **18.1-3** at 37 °C for 20 hours resulted in a release profile that was similar to the one obtained using an AMF. This result is remarkable — carbonate and carbamate functionalities undergoing hydrolysis at pH 7.4 at 37 °C. This import of this finding is put into perspective on comparison with current hydrolytic examples from the literature (Scheme 4.4) that show the forcing conditions needed to cleave carbonate and carbamate functionalities. It became obvious that the Fe₃O₄ NPs must be exerting some effect to accelerate the hydrolyses, even in the absence of an AMF.

Scheme 4.4. Examples from current literature of the hydrolysis of A. an ester,⁵² B. a carbonate⁵³ and C. a carbamate.⁵⁴ Conditions: *a.* H₂O, DMSO, rt, 42 h, 58%; *b.* 5 M NaOH, MeOH, rt, 3 d, 90%; *c.* KOH, N₂H₄, (CH₂OMe)₂, 200 °C, 80%.

To attempt to explain the iron oxide NP hydrolysis phenomenon we started to investigate the catalytic and physical attributes of iron. The Fe₃O₄ NPs are comprised of a mixture of both Fe²⁺ and Fe³⁺ at a molar ratio of 1:2, respectively.⁴⁷ Since Fe₃O₄ is readily oxidized to Fe₂O₃ (Fe³⁺) when exposed to air, changing the NP color from black to an orange/red color, it is not uncommon for the NPs to have an oxidized layer of Fe₂O₃ or Fe³⁺.⁵⁵ With this in mind, we researched the properties of iron(III) and found that iron(III) oxides are a known Lewis acid, thus making them capable of selectively binding to Lewis bases (e.g., heteroatoms, particularly carbonyl oxygens).⁵⁶ The Lewis acid-Lewis base concept could help explain why the carbonate and carbamate groups were hydrolyzed to a greater extent than the ester. The attribute of both the carbonate and carbamate that adds to their hydrolytic stability is the increased electron density supplied

to the carbonyl, thus making it less susceptible to nucleophilic attack at the carbonyl carbon by water. As can be seen from Scheme 4.4, the hydrolysis of carbonates and carbamates require highly basic reaction conditions and, in the case of the carbamate, high temperatures. These conditions are all methods of enhancing the nucleophilicity of water/hydroxyl groups. But this hydrolytic acceleration can also be achieved with Lewis acids that, instead of increasing nucleophilicity, enhance the electrophilicity of the carbonyl and allow a weaker nucleophile to attack an otherwise stable functional group. This knowledge led us to postulate a possible mechanism for the Fe_3O_4 NP accelerated hydrolysis that is shown in Figure 4.21.

Figure 4.21. Proposed mechanism for Fe_3O_4 NP accelerated hydrolysis of esters, carbonates and carbamates under mild conditions.

4.2.5. Suppression of Hydrolysis

Our attention was now turned to possibly masking the Lewis acidity at the surface of the magnetic NPs. The first approach we tried was to coat the functionalized NPs with either the disaccharide D-lactose or the polysaccharide dextran. The idea in using these substrates was to effectively mask the unfunctionalized portions of magnetic NPs

(Scheme 4.5a). The hydroxyl groups of the carbohydrate or polymer would hydrogen bond to the NP surface and prevent the Lewis basic carbonyl oxygen from coordinating with the NP surface. We postulated that application of an AMF would aid in the release of the hydrogen bound carbohydrate or polymer, allowing the NP accelerated hydrolysis to occur. The second method of preventing the rapid, non-triggered hydrolysis was to coat the unfunctionalized Fe₃O₄ NPs with a silica shell and then load the linkers onto the silica surface (Scheme 4.5b). Though silica can still serve as a Lewis acid, its acidity, in comparison to iron oxides, is far less since its Lewis acid centers are developed only from silicon atoms in a strained siloxane bridge.⁵⁷ In this case the strained covalent bond causes the formation of a dipole, thus causing the silicon atom to become electron deficient and Lewis acidic. By using a silica shell around the iron oxide NP we would provide a permanent shield to prevent the linkers from interacting with the iron core. The linker-NP bond would also be strengthened and easier to form since we would be seeking to form Si–O–Si bonds instead of Fe–O–Si bonds during linker loading. As was previously stated, all Metal–O–Si bonds are inferior to the highly stable Si–O–Si bonds.⁴³

Scheme 4.5. Attempts to mask the iron oxide NP surface. A: coating the functionalized NPs with polysaccharides; B: coating the iron oxide core with a silica shell. Conditions: *a*. D-lactose or dextran (6 kd); *b*. tetraethyl orthosilicate, NH_4OH , EtOH, H_2O ; *c*. i. **17.2**, $(\text{EtO})_3\text{SiH}$, cat. PtO_2 , 90°C , ii. add alkoxy silane to NPs.

The 37°C incubation experiment was repeated to compare the release rate of **18.2** with that of **19.1-2** and **20** and to see if we were able to effectively minimize non-AMF induced hydrolysis. As can be seen from Figure 4.22, the polysaccharides did slightly reduce the rate of hydrolysis with **19.2** being more effective. Since the vast majority of the non-AMF induced hydrolysis occurred soon after the incubation began, Figure 4.22 has focused only on the first 2 hours of incubation. This was especially true at the beginning of the experiment but the lack of a covalent bond resulted in a large amount of the mask dissociating from the NP surface. The silica shell of **20** greatly increased the

hydrolytic stability of the linker. We continued all further experiments with $\text{SiO}_2@\text{Fe}_3\text{O}_4$ NPs.

Figure 4.22. Non-triggered (i.e., no AMF application) hydrolysis of ~7 mg **18.2** compared with the suppressed hydrolysis of **19.1-2** and **20** at 37 °C in 2:1 PBS:MeCN pH 7.4.

4.2.6. Commencement of $\text{SiO}_2@\text{Fe}_3\text{O}_4$ NPs

With non-AMF induced hydrolysis sufficiently minimized, we returned to the investigation of AMF-induced intramolecular cyclization. Using the kinetic study discussed in Chapter 3 (Figure 3.11 and Table 3.2), we selected **9** as the optimal linker. It afforded thermal stability over short periods of time at 55 °C while remaining thermally responsive over extended intervals. Consequently, we set out to evaluate the feasibility

of AMF-mediated oxazolidinone formation as a mechanism for drug release by covalently attaching **9** to SiO₂@Fe₃O₄ NPs (Scheme 4.6).

Scheme 4.6. Synthesis of NP-carbonate linker conjugates with anthracenyl fluorophore (Ar = 9-anthracenyl). Conditions: *a.* (EtO)₃SiH, cat. PtO₂, 90 °C; *b.* SiO₂@Fe₃O₄, EtOH, H₂O; *c.* i. CF₃CO₂H : CH₂Cl₂, 1:1, 0 °C, 1 h; ii. Et₃N : CH₂Cl₂, 1:1, rt.

After adding the alkoxy silane to **9** through the PtO₂-catalyzed hydrosilylation described by Sabourault *et al.*⁵⁸ the linker was bound to SiO₂@Fe₃O₄ NPs. The Boc group was once again cleaved by treatment with trifluoroacetic acid followed by neutralization with triethylamine to afford **22** with the unmasked nucleophilic amine needed for the AMF-induced intramolecular cyclization.⁵⁹ The success of the Boc-deprotection could be qualitatively observed by the formation of a white cloud when the 1:1 triethylamine:CH₂Cl₂ solution was added to the coated NPs. The basic solution was added after the removal of excess TFA with five washes of CH₂Cl₂.

A suspension of the free-amine NPs **22** in a 2:1 mixture of PBS:acetonitrile (pH adjusted to 7.4) at room temperature was sequentially pulsed with an AMF for six 5-

minute bursts with a delay time of 5 minutes between pulses. Magnetic-assisted sedimentation of the NPs allowed facile measurement of supernatant fluorescence at the end of each pulse (Figure 4.23). To confirm that we were releasing only the 2-(9-anthracenyl)ethanol and not another fragment we analyzed the 2:1 PBS:acetonitrile supernatant that was used to suspend **22** during AMF exposure using matrix-assisted laser desorption ionization (MALDI) time of flight (TOF) mass spectrometry (MS) (Figure 4.24). The data show an AMF-promoted release of 2-(9-anthracenyl)ethanol (Figure 4.25) presumably as a consequence of the expected amine addition to the proximal carbonate moiety.

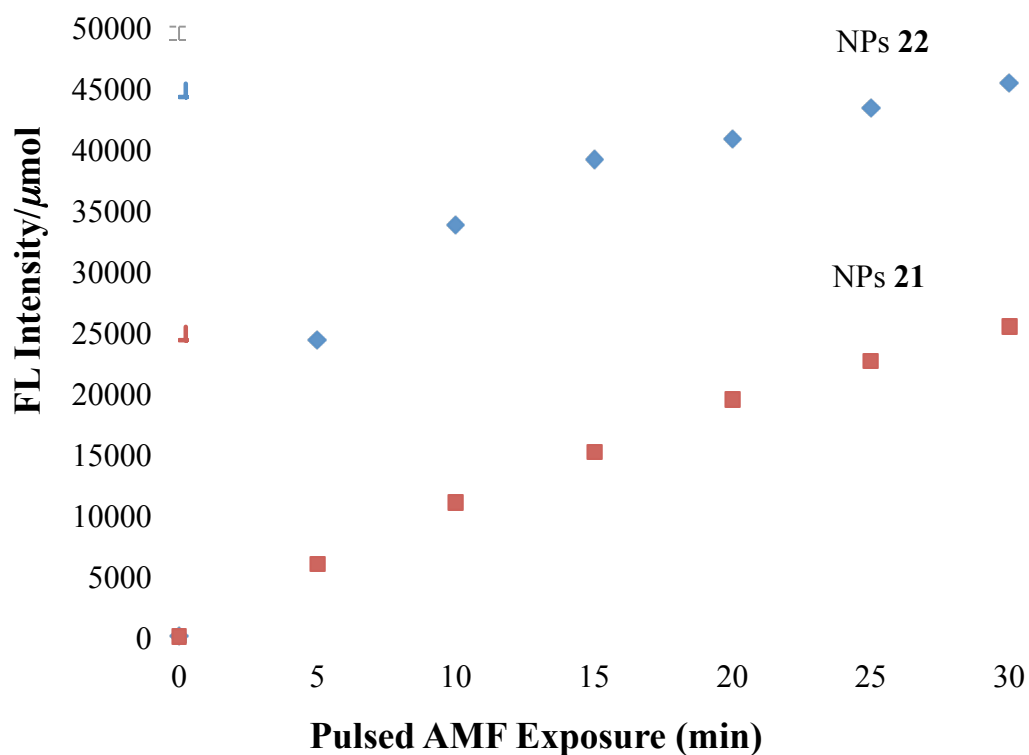

Figure 4.23. AMF-induced release of anthracene fluorophore from NPs **21** (red) and **22** (blue). NPs (6-8 mg) suspended in 2:1 PBS:acetonitrile (0.75 mL) at pH 7.4 were irradiated with an AMF (501.6 amps, 204 kHz) for 5-minute bursts followed by 5-minute intervals. Vertical axis shows fluorescence intensity normalized to mmol of bound anthracene fluorophore as determined by thermogravimetric analysis.

Figure 4.24. Procedure used to obtain sample for MALDI-TOF analysis and verification of released substrate.

Figure 4.25. MALDI-TOF spectrum using a 2,5-dihydroxybenzoic acid matrix of the radical carbocation⁶⁰ 2-(9-anthracenyl)ethanol released from **22**. The sample was acquired from the 2:1 PBS:acetonitrile supernatant used during the AMF treatment of **22**.

To test the proposed mechanism of substrate release, we examined the Boc-protected NPs **21**, which would be incapable of undergoing the postulated intramolecular cyclization, under identical conditions. To our surprise, fluorophore release from **21** also occurred in response to AMF irradiation, albeit at a rate slower than the free amine formulation (Figure 4.23). This result pointed toward enhanced hydrolysis as a function of the energy deposited by AMF irradiation. Despite the reduced Lewis acidity of the SiO₂@Fe₃O₄ NPs, the significant, rapid heating within nanometers of an iron oxide NP surface could still explain this phenomenon.⁶¹ On examination of the stability of NPs **21** under the same conditions but without AMF irradiation, we noted the gradual release of 2-(anthracen-9-yl)ethan-1-ol over an hour at 37 °C to ~50% of the cumulative level achieved by the six 5-minute bursts of AMF irradiation. This finding, while precluding the use of **21** (or **22**) as a drug delivery system, is noteworthy because dialkylcarbonates are stable to such mild conditions and generally require highly basic conditions for their hydrolysis (e.g., 5M NaOH, MeOH, rt, 3d⁵³). As a control, exposure of free carbonate **9** (Scheme 4.6) to SiO₂@Fe₃O₄ NPs in 2:1 phosphate buffer solution (PBS):acetonitrile at 37 °C resulted in no reaction, even after 24 h exposure. Consequently, we surmised that the close proximity and tethered relationship of the carbonate linkage in **21** to the iron oxide core and silica shell enhance, possibly through Lewis acid or hydrogen bonding interactions, respectively, the rate of hydrolysis of this linkage. This reasoning supports the previously postulated mechanism (Figure 4.21).

4.2.7. Monodispersed SiO₂@Fe₃O₄ Nanoparticles

To gain a better understanding of **21**, we had Dr. Jacek Jasinski (Conn Center for Renewable Energy, University of Louisville) obtain transmission electron microscopy (TEM) images. As can be seen from the High Angle Annular Dark Field (HAADF) scanning transmission electron microscopy (STEM) images in Figure 4.26, the iron oxide NPs are largely aggregated and the silica shell is visible (a somewhat cloudy surrounding) at the outer perimeter of each iron cluster. Iron oxide NPs are notorious for aggregating due to their anisotropic dipolar attraction.⁶² The most popular method of internalization of NPs into cells is through endocytosis.⁶³ For clathrin-mediated endocytosis, the NPs can be up to 100 nm in diameter and for caveolae mediated endocytosis the diameter can be no greater than 60-80 nm.⁶⁴ As is evident, the mandates of endocytosis make NP aggregation an undesirable attribute for drug delivery.

Figure 4.26. HAADF Z-contrast STEM image of aggregated Fe_3O_4 NPs with a thick silica shell surrounding them.

To prevent the aggregation the Fe_3O_4 NPs, a surfactant must immediately be applied to the surface of the NP. One of the most common surfactants used in the synthesis of monodispersed Fe_3O_4 NPs is oleic acid or its sodiated derivative. Following a two-step route described by Park *et al.*⁶⁵ we synthesized oleate-coated Fe_3O_4 NPs via high-temperature (320 °C) decomposition of the organic precursor that was generated *in situ*. Fe_3O_4 -oleate NPs can also be prepared through a co-precipitation method as reported by Jiang *et al.*⁶⁶ After obtaining the magnetic NPs we attempted to add the silica shell to the surface. Silica shells are usually added to iron oxide NPs using the Stöber process,⁵⁰ but the presence of the oleate surfactant prevented the NPs from being dispersible in the standard ethanol/water mixture. To circumvent this issue using

microemulsion, Ding and coworkers⁶⁷ suspended the Fe₃O₄-oleate NPs in cyclohexane that was basified with NH₄OH. Using another surfactant, Igepal CO-520, the oleate surfactant is removed and replaced by the Igepal CO-520. This surfactant exchange allows the ammonia, in the form a droplet containing the hydrolyzed tetraethyl orthosilicate (TEOS), to draw near to the NP and deposit the silica onto the NP surface (Scheme 4.7). Though similar methods using Igepal CO-520 are frequently reported,⁶⁸ we found the collection of the SiO₂@Fe₃O₄ NPs to be very difficult. Magnetic separation cannot be used and centrifugation causes both the NPs and the surfactant to form a gelled pellet, resulting in an unusable paste. When the Stöber process was attempted with the Fe₃O₄-oleate NPs there was rampant aggregation resulting in particles with a hydrodynamic diameter of 2065.2 ± 284.6 nm.

Scheme 4.7. Illustration of the microemulsion coating mechanism of SiO_2 on the surface of Fe_3O_4 -oleate NPs.⁶⁷

We also investigated the use of hydrophilic surfactants. Jing *et al.*⁶⁹ used iron(II) sulfate in an oxidative coprecipitation synthesis of Fe_3O_4 NPs. Briefly, $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ and sodium citrate were co-added to an aqueous solution of sodium nitrate and potassium hydroxide. The solution was heated to 90 °C for 5 h under an inert atmosphere before cooling to room temperature and precipitating the NPs from solution with acetone. The NPs could then be easily collected by magnetic separation. These NPs, though easy to suspend in water, still showed signs of aggregation with a hydrodynamic diameter of 294.8 ± 11.7 nm. When the silica shell was added to the Fe_3O_4 -citrate NPs the hydrodynamic diameter increased to 453.8 ± 8.8 nm.

We then looked into the use of commercial ferrofluid containing Fe_3O_4 NPs (EMG 304, FerroTec). We chose a procedure reported by Lu and coworkers⁶² due to its rapid application (3 hours) of a thin silica shell around Fe_3O_4 NPs. As mentioned previously, as the thickness of the silica shell increases there is a sharp reduction in the magnetism of the NP.⁴⁹ This reduction in magnetism decreases the AMF-induced energy and could potentially eliminate our ability to activate thermally-induced reactions. The dynamic light scattering (DLS) measurements showed a hydrodynamic diameter of 310 ± 3.7 nm with a polydispersity of 0.23 ± 0.01 (Figure 4.27). The ζ -Potential of the $\text{SiO}_2@\text{Fe}_3\text{O}_4$ NPs was -19.50 ± 9.12 mV with a mobility of -0.39 ± 0.18 . Though the DLS measurements still showed two distinct sizes of NPs with a larger than desired diameters we proceeded to obtain TEM images because Lu *et al.*⁶² had also used EMG 304 ferrofluid to create their $\text{SiO}_2@\text{Fe}_3\text{O}_4$ NPs. The TEM (Figure 4.28) show a very thin silica shell but there is large-scale aggregation as well.

Figure 4.27. DLS of $\text{SiO}_2@\text{Fe}_3\text{O}_4$ NPs in EtOH showing the hydrodynamic diameter at 310 nm with a polydispersity of 0.23.

Figure 4.28. TEM image of $\text{SiO}_2@\text{Fe}_3\text{O}_4$ NPs synthesized from EMG 304 showing excessive aggregation.

Because we were unable to reproduce the results of Lu *et al.*,⁶² we moved to a modified version of the Stöber process as reported by Pinho *et al.*⁷⁰ This procedure was especially attractive as it included an equation, that allowed for the thickness of the silica shell to be adjusted by varying the amount of TEOS. Using the volume of TEOS needed to afford a 4 nm thick silica shell, Fe_3O_4 NPs in the EMG 304 ferrofluid with a reported average diameter of 10 nm were silylated to form monodispersed superparamagnetic (Figure 4.29) $\text{SiO}_2@\text{Fe}_3\text{O}_4$ NPs with a particle size distribution of 24 ± 6 nm and a silica shell thickness of 6-7 nm, as determined by TEM (Figure 4.30). The monodispersed $\text{SiO}_2@\text{Fe}_3\text{O}_4$ NPs had a ζ -Potential of -46.58 ± 0.47 mV and a mobility of -3.64 ± 0.04 in Millipore water. The DLS measurements (Figure 4.31) showed a hydrodynamic diameter of 103 nm and a polydispersity of 0.17.

$$V_{TEOS} = N_{part} \left[\frac{\rho_{SiO_2} M_{TEOS}}{M_{SiO_2} \rho_{TEOS}} \right] \left[\frac{4}{3} \pi ((r + e_{shell})^3 - r^3) \right]$$

Equation 4.1. Equation used to calculate the volume of TEOS required to obtain a silica shell of a desired thickness, where V_{TEOS} is the volume of TEOS required, N_{part} is the number of Fe_3O_4 NPs to be coated, ρ_{SiO_2} is the density of silica, M_{TEOS} is the molecular weight of TEOS, M_{SiO_2} is the molecular weight of silica, ρ_{TEOS} is the density of TEOS, r is the average radius of the Fe_3O_4 NPs, and e_{shell} is the desired thickness of the silica shell.

Figure 4.29. Superconducting quantum interference device (SQUID) measurement of $SiO_2@Fe_3O_4$ NPs prepared from EMG 304. Measurements were taken at temperatures from 2 to 400 K and magnetization data was taken by cycling from -5 T to 5 T. SQUID measurements were taken by Professor Lance DeLong, University of Kentucky.

Figure 4.30. A. TEM image of $\text{SiO}_2@\text{Fe}_3\text{O}_4$ NPs synthesized from EMG 304 with a B. particle size distribution of 24 ± 6 nm and a silica shell thickness of 6-7 nm.

Figure 4.31. DLS of SiO₂@Fe₃O₄ NPs in Millipore water showing the hydrodynamic diameter at 103 nm with a polydispersity of 0.17.

When the monodispersed SiO₂@Fe₃O₄ NPs with a 10 nm Fe₃O₄ core and a 6-7 nm thick silica shell were subjected to pulsed AMF irradiation at a concentration of 7 mg of NPs in 2:1 PBS:acetonitrile (0.75 mL), the temperature of the bulk suspension, as confirmed by measurements taken using a fiber optic temperature sensor, increased +16.4 ± 0.3 °C from the start of the AMF pulse to the end of the AMF pulse and increased +4 °C from start of the first pulse to the start of the sixth pulse (Figure 4.32).

Figure 4.32. AMF-induced heating/cooling of 2:1 PBS:acetonitrile (0.75 mL) (blue), SiO₂@Fe₃O₄ NPs (7 mg) in 2:1 PBS:acetonitrile (0.75 mL) (red), AMF 5 min on/off sequence (green). A. 5 minute pulse duration and B. 2 minute pulse duration. AMF conditions: 500 amps, 204 kHz.

4.2.8. AMF-Induced Hydrolysis

Figure 4.33. AMF-triggered hydrolysis of pendant functionality (FL = anthracene fluorophore, •; carbamate moiety, n; terminal amine residue, n).

Since we were still observing significant AMF-induced hydrolysis (Figure 4.23, **21**) and continuing to lose ~50% of the NP loading during Boc-deprotection, we decided to embrace the observed AMF-induced hydrolysis. As depicted graphically in Figure 4.33, we engineered a new linker by first removing the nucleophilic element and, second, we replaced the carbonate moiety with an *N*-methyl carbamate linkage in order to effectively increase the hydrolytic stability of the carbonyl (Scheme 4.8). Even unsubstituted carbamates are extremely resistant to hydrolysis and typically require treatment with base under forcing conditions for cleavage (e.g., KOH, diglyme, 200 °C).⁵⁴ We also adopted a strategy for convenient attachment of substrate to the simplified carbamate-linked NPs, namely oximation (Schemes 4.8 and 4.9). We⁷¹ and others⁷² have used the click chemistry reaction⁷³ of NP-bound aminoxy groups with aldehydes to form oxime ethers as a convenient means for surface functionalization. Any newly formed oxime ether linkage would be sufficiently resistant to hydrolysis and thereby decrease the risk of a non-AMF induced release.⁷⁴

Scheme 4.8. Synthesis of linkers for substrate release via AMF-induced hydrolysis. Conditions: *a.* TBSCl, Et₃N, CH₂Cl₂, 0 °C; *b.* 1,1'-carbonyldiimidazole, (*i*-Pr)₂NEt, CH₂Cl₂, 0 °C; *c.* DBU, MeCN, rt, 79% over 3 steps; *d.* TBAF, THF, 0 °C; *e.* MsCl, Et₃N, CH₂Cl₂, 0 °C; *f.* *N*-hydroxyphthalimide, K₂CO₃, DMSO, 75 °C, 71% over 3 steps; *g.* N₂H₄•H₂O, CH₂Cl₂, 0 °C, 96%.

After preparing the SiO₂@Fe₃O₄ NPs, the residual ammonia from the Stöber process was removed prior to NP functionalization by placing the ethanol/water suspension of SiO₂@Fe₃O₄ NPs under mild vacuum and then heating at 60 °C for 8h. Removal of the ammonia in this way decreased the pH of the suspension from 11.7 to 8.8. The resultant SiO₂@Fe₃O₄ NPs then were functionalized by adding an ethanolic

solution of the triethoxysilane-derived linker obtained from PtO₂-catalyzed⁷⁵ hydrosilylation of alkene **23** with (EtO)₃SiH to obtain **24** (Scheme 4.9).

Scheme 4.9. Linkers designed for release via AMF-induced hydrolysis bound to SiO₂@Fe₃O₄ NPs. Conditions: *a.* (EtO)₃SiH, cat. PtO₂, 90 °C; *b.* SiO₂@Fe₃O₄, EtOH, H₂O, rt, 12 h, *c.* 2-(9-anthryl)acetaldehyde,⁷⁶ (**26**), EtOH, H₂O, rt, 8 h.

The functionalization of the SiO₂@Fe₃O₄ NPs with hydrosilylated **23** increased the shell thickness by ~3 nm to afford AO@SiO₂@Fe₃O₄ NPs with a diameter of 30 ± 8 nm as determined by TEM (Figure 4.34). The hydrodynamic diameter of aqueous AO@SiO₂@Fe₃O₄ NPs was measured at 96 nm with a polydispersity of 0.16, roughly similar to the hydrodynamic diameter of the starting SiO₂@Fe₃O₄ NPs at 103 nm with a polydispersity of 0.17 (Figure 4.35). We also observed little change in ζ-potential, where both the SiO₂@Fe₃O₄ and AO@SiO₂@Fe₃O₄ NPs registered *ca.* – 45 mV as aqueous suspensions. Simple mixing of AO@SiO₂@Fe₃O₄ with anthracene aldehyde **26** (Scheme 4.9) in aqueous ethanol gave NPs **25** (FL@SiO₂@Fe₃O₄). In an alternate approach, we conducted the oximation step first by reacting anthracene aldehyde **26** with **23** (Scheme 4.9) followed by hydrosilylation of the oxime ether adduct and then loading onto SiO₂@Fe₃O₄ NPs to obtain **25**.

Figure 4.34. A. TEM image of AO@SiO₂@Fe₃O₄ NPs with a B. particle size distribution (30.4 ± 0.8 nm) resulting in a ~ 3 nm increase in the NP radius.

Figure 4.35. DLS of AO@SiO₂@Fe₃O₄ NPs in Millipore water showing the hydrodynamic diameter at 96 nm with a polydispersity of 0.16.

With the FL@SiO₂@Fe₃O₄ NPs in hand, we studied the AMF-induced hydrolysis of the carbamate linkage by measuring the release of anthracene oxime ether fragment **27** (Scheme 4.10). The AMF experiments were conducted as described above (2:1 PBS:acetonitrile solution, pH 7.4). As can be seen in Figure 4.36, AMF irradiation stimulated a rapid release of substrate from FL@SiO₂@Fe₃O₄. MALDI-TOF analysis confirmed that the oxime ether-anthracene fragment **27** was liberated from the NP formulation on AMF irradiation (Figure 4.37). Based on fluorescent measurements, 40 minutes of AMF exposure resulted in $67 \pm 3\%$ of payload release; longer exposure times did not release additional **27**. We also tested different currents by subjecting the NPs to 100 amps and 300 amps and compared the release with the results from the previous experiment (Figure 4.38). In addition, we also varied the duration of each AMF pulse from 5-minute on/off pulses to 2-minute on/off pulse with a total AMF exposure time of 40 minutes for both samples. As can be seen in Figure 4.39, the release of **27** is controlled by total AMF exposure time and not by the duration of the pulsing sequence. We were also gratified to find that the switch from carbonate to carbamate dramatically

reduced non-AMF release of substrate — less than 10% of the payload was released at 37 °C after 40 minutes. The rapid release of the fluorophore fragment on AMF application is quite remarkable in that *N,N*-dialkyl carbamates are not expected to cleave under these mild conditions (e.g., a previous kinetic study estimates a typical half-life of >550 years at 25 °C and pH 7).⁷⁷

Scheme 4.10. AMF-induced carbamate hydrolysis.

Figure 4.36. AMF-induced release of **27** from FL@SiO₂@Fe₃O₄ (blue): NPs in PBS:acetonitrile were irradiated with an AMF (501.6 amps, 204 kHz) for 5-minute bursts followed by 5-minute intervals; release of **27** from FL@SiO₂@Fe₃O₄ (red): NPs in PBS:acetonitrile were incubated at 37 °C for the indicated time. Vertical axis shows the percent of **27** released as determined by fluorescent measurements; n = 3.

Figure 4.37. MALDI-TOF spectra of the radical carbocation⁶⁰ of the anthracenyl oxime ether of **23** (bottom, green) and **27** (top, blue) after AMF-induced hydrolysis and release from FL@SiO₂@Fe₃O₄ NPs (**25**). The MALDI-TOF analysis of the anthracenyl oxime ether of **23** shows that the appearance of **27** is not a result of fragmentation during MS analysis.

Figure 4.38. AMF-induced release, as determined by fluorescence measurements, of **27** from FL@SiO₂@Fe₃O₄ NPs in 2:1 PBS:acetonitrile at AMF amperages of 100.7 (n=1), 300.2 (n=1) or 501.6 (n=3). The control, incubated at 37 °C for the indicated time, received no AMF pulses.

Figure 4.39. AMF-induced release of **27** from FL@SiO₂@Fe₃O₄ NPs during 2 minute (n=1) or 5 minute (n=3) AMF pulses at 501.6 amps versus incubation at 37 °C.

4.3. CONCLUSION.

The use of a thermally susceptible bond, such as in the azo system recently disclosed by Riedinger *et al.*,⁶¹ enables several possibilities for controlled drug delivery from iron oxide NPs when using an AMF as an external stimulus. In the present study, we have observed the AMF-stimulated release of fluorescent substrates from short-chain carbonate- and carbamate-based linkers covalently attached to magnetic iron oxide–silica, core–shell NPs. Although the mode of catalysis for the cleavage of the carbonate and carbamate functional groups is unclear at this time, AMF-induction, likely through

accompanying local hyperthermia, dramatically enhances hydrolyses of these otherwise highly stable chemical linkages. This first example of an AMF-induced hydrolysis of a carbamate linkage may find utility in the development of externally triggerable delivery systems. In particular, the ease of carbamate synthesis, especially in the context of conjugating substrates to NPs, and the lower hydrolytic susceptibility of the *N,N*-dialkyl carbamate linkage in the absence of AMF exposure combine to make AMF-mediated functional group hydrolysis a promising strategy for regulated nanoparticle delivery of substrates.

4.4. FUTURE DIRECTIONS.

It is still unclear why the release of the fluorophore always stops at approximately 65%. As was stated by Riedinger *et al.*,⁶¹ the energy produced by the iron oxide NPs in the presence of an AMF dissipates rapidly as the distance from the NP core is increased. We suspect that the remaining ~35% of the loading that does not release is too far away from the iron oxide core to induce the accelerated hydrolysis. This hypothesis is quite reasonable in that the alkoxy silane can undergo self-condensation, or polymerization, prior to being attached to the NP surface. This theory could be tested by incorporating poly(ethyleneglycol) (PEG) chains of varying length into the linker between the NP and the carbonyl functionality. Modification of the linker with PEG would increase the distance of the carbonyl from the NP and help to determine at what distance the hydrolytic phenomenon ceases. Elucidation of the reaction mechanism of the enhanced hydrolysis would also supply much needed information to further explain this surprising reaction.

To advance this research to the next level, i.e., *in vivo* studies, we have partnered with Dr. Ralf Schirmacher, a research scientist in Oncology at the University of Alberta Medical Isotope & Cyclotron facility. Together with his post doctoral student Dr. Jun Zhu, they obtained gold coated Fe_3O_4 NPs using a procedure outlined in Scheme 4.11. Figure 4.40 shows the TEM image of the $\text{Au}@\text{Fe}_3\text{O}_4$ NPs and Figure 4.41 are the SQUID measurements showing superparamagnetism.

Scheme 4.11. Synthesis of $\text{Au}@\text{Fe}_3\text{O}_4$ NPs.

Figure 4.40. TEM image of $\text{Au}@\text{Fe}_3\text{O}_4$ NPs.

Figure 4.41. SQUID measurements of Au@Fe₃O₄ NPs showing superparamagnetism.

To allow for covalent binding of our linkers to the surface of the Au@Fe₃O₄ NPs we replaced the unsaturation with a protected thiol (Scheme 4.12). Gold is a very attractive surface because it allows for easy covalent attachment of the linker to the NP through the Au–S bond and is known to have very good biocompatibility.⁷⁸

Conditions: *a.* TBSCl, Et₃N, CH₂Cl₂, 0 °C, 17 h; *b.* MsCl, Et₃N, CH₂Cl₂, 0 °C, 1.5 h; *c.* phthalimide, K₂CO₃, DMSO, 75 °C, 18 h; *d.* N₂H₄•H₂O, 1:2 EtOH:CH₂Cl₂, 20 h; *e.* 1,2-dibromoethane, K₂CO₃, THF, reflux, 24 h, 98%; *f.* MeCN, 55 °C, 24 h, 82%; *g.* Boc₂O, Et₃N, CH₂Cl₂, 0 °C, 2 h; *h.* 1 M TBAF in THF, THF, 0 °C, 20 h, 62%; *i.* 1,1-carbonyldiimidazole, (*i*-Pr)NEt, CH₂Cl₂, 0 °C, *j.* 2-bromoethanol, AcONa, DMSO, 70 °C, 67%; *k.* DBU, MeCN, 18 h, 55%; *l.* N₂H₄•H₂O, CH₂Cl₂, 0 °C, 92%.

By transitioning from SiO₂@Fe₃O₄ NPs to Au@Fe₃O₄ NPs we suspect that hydrolysis will no longer occur. This hypothesis is based on the elimination of the Lewis acidic iron oxide surface. In the absence of hydrolysis we have resorted back to intramolecular cyclization as a release mechanism. Another problem that we had previously faced was the loss of ~50% of the NP loading during the acidic Boc-deprotection when performed on the functionalized NPs. By using a thiol attachment and careful choice of protecting groups we have circumvented this issue. Standard Boc-deprotection usually involves a reaction with trifluoroacetic acid. These acidic conditions

will also cleave the trityl thiol-protecting group. After performing the dual acidic deprotection, the Au@Fe₃O₄ NPs can be loaded without the risk of premature intramolecular cyclization. Leaving the linker in the form of an aminium salt prevents nucleophilic attack of the carbonyl by the amine. After the Au@Fe₃O₄ NPs are functionalized, a base wash restores the nucleophilic amine, thus enabling intramolecular cyclization.

My laboratory co-worker, Ms. Sara Biladeau, is currently attaching the aldehyde functionalized fluorophore 4,4-difluoro-4-bora-3a,4a-diaza-s-indacene (BODIPY)⁷⁹ through the oximation reaction and loading the linkers onto the Au@Fe₃O₄ NPs.

5.1. GENERAL STATEMENT

All solvents and reagents used in this thesis were reagent grade and were used as received unless otherwise indicated. Dry THF and CH₂Cl₂ were obtained from SPBT-101 Bench Top Solvent Purification System (LC Technology Solutions, Inc., USA). Anhydrous DMF was purchased from Sigma-Aldrich. Dry acetonitrile was obtained by distillation from CaH₂. Unless otherwise noted, all reagents were purchased from commercial suppliers and were used without further purification. The progress of reactions was monitored by thin-layer chromatography (TLC) using pre-coated silica plates (EMD Silica Gel 60 F254). Visualization was accomplished by staining the plates with iodine, PMA (3% phosphomolybdic acid/ethanol solution), PAA stain (2.5% p-anisaldehyde acid/ethanol solution) or ninhydrin stain (10 g ninhydrin in 100mL of *n*-butanol and add 3 mL AcOH). UV active compounds were visualized by UV light (254 nm). Silica gel 60 (230-400 mesh) was used for flash column chromatography. ¹H NMR spectra were recorded at 400, 500 or 700 MHz, and ¹³C spectra were recorded at 100, 125 or 175 MHz, respectively, in the indicated solvents. The chemical shifts are reported in ppm values relative to the solvent residual peak CDCl₃ (7.26 ppm for ¹H NMR and 77.23 ppm for ¹³C NMR), DMSO-*d*₆ (2.50 ppm for ¹H NMR and 39.52 ppm for ¹³C NMR), CD₃OD (3.31 ppm for ¹H NMR and 49.00 ppm for ¹³C NMR) or toluene-*d*₈ (2.08 ppm for ¹H NMR and 20.43 ppm for ¹³C NMR). Coupling constants are reported in hertz (Hz). High resolution ESI-MS were obtained using a FT-ICR-MS system (LTQ FT, Thermo Electron Corp.) at the Center for Regulatory and Environmental Analytical Metabolomics (CREAM) Mass Spectrometry Facility, University of Louisville, Kentucky. Fluorescent measurements were taken on a Molecular Devices SpectraMax M5 in fluorescent mode at

an excitation of 366 nm and emission wavelength of 408 nm. The fluorescent measurements were taken using a quartz semi-micro VWR Spectrosil spectrophotometer cell with a 10 mm light path. Transmission electron microscopy (TEM) was used to analyze size distribution and morphology of fabricated nanoparticles, including uniformity and thickness of silica coating. For this, ethanol-based nanoparticle dispersions were prepared and drop-casted on commercially available 300 mesh TEM support Cu grids coated with ultra thin carbon films. After ethanol evaporation, samples were transferred to and analyzed using a field emission gun FEI Tecnaci F20 transmission electron microscope operating at the accelerating voltage of 200 kV. TGA measurements were made on a TA Instruments Hi-Res TGA 2950 Thermogravimetric Analyzer using a Pt basket and maintaining a flow of N₂ gas through the oven. Each TGA experiment was run from 35 °C to 800 °C at a ramp rate of 20 °C/min. DLS and ζ-potential measurements were taken using a Brookhaven Instruments 90Plus Particle Size Analyzer. All measurements were taken using aqueous colloids of the nanoparticles in Millipore water. The alternating magnetic field (AMF) was generated with an Ambrell EasyHeat L1 set at 501.6 amps and 204 kHz using a 5-turn coil. MALDI-TOF analysis was done on a Voyager DE-Pro MALDI-TOF instrument (PE Biosystems). Spectra were acquired in positive reflectron mode and calibration was achieved by using known peaks from the 2,5-dihydroxybenzoic acid (2,5-DHB) matrix. Data was analyzed with mMASS data analysis software.

5.2. EXPERIMENTAL PROCEDURES FROM CHAPTER 2

5.2.1. Open- and Closed-Chip Microreactor Fabrication

Dr. Xiao-An Fu's research group designed and fabricated the open-chip microreactor in a way that mirrored the microelectromechanical system procedures described previously.^{1, 2, 3} Deep reactive ion etching (DRIE) was used to create microfluidic channels and micropillars with a height of roughly 250 μm on a silicon wafer. The microreactor channels and micropillars were thermally oxidized to form a 50 nm SiO_2 thin film in an O_2 and H_2O atmosphere. The silicon microreactors have a 7 x 5 mm microfluidic channel consisting of over 2500 micropillars with a surface area of about 130 mm^2 .

The open-chip microreactors were completed by directly dicing the silicon wafer after the thermal oxidation process. The microreactors were functionalized with AMAH by placing the chip into a 20 mL clean-air sampling vial. Then, a solution of AMAH (140 μg , 7.67×10^{-7} mol) dissolved in methanol (20 μL) was added into the microfluidic channel of the chip. The vial was put into an oven and dried for 5 minutes at 85 $^\circ\text{C}$.

Closed-chip microreactors were prepared by bonding the wafer-supported microreactors with a Pyrex glass wafer using an anodic wafer bonding process. Each wafer was subsequently diced, and the connection ports were opened for connecting fused silica tubes to the microreactors. The surface of the micropillars in the closed-chip was functionalized with AMAH by infusing a solution of AMAH (67 μg , 3.65×10^{-7} mol) in methanol (15 μL) into the microreactors followed by evaporation of the solvent under vacuum. Finally, fused silica tubes with 190 μm o.d. and 100 μm i.d. were

connected to the inlet and outlet ports of the microreactor, respectfully, with a silica-based bonding agent.

5.2.2. Open-Chip Sample Collection

To test the open chip for capture of trace carbonyl compounds, exhaled breath samples were collected. After approval by the Internal Review Board of the institution and after having obtained written informed consent, exhaled breath samples were collected from healthy never-smokers, current smokers and lung cancer patients. To collect a breath sample, the subject used a straw to blow into the sampling vial containing the open-chip for 15 minutes. During this process, the carbonyl compounds in the exhaled breath react with the AMAH coating and are retained in the microreactor while the rest of the breath sample moves freely away and out of the sampling vial. After the subject had finished blowing, methanol (10 μL) was added into the microfluidic channel to dissolve the analytes. The methanol solution was then removed from the microreactor using a pipette. This process was repeated four more times to collect an approximate total of 50 μL of a methanol-analyte mixture for analysis.

5.2.3. Determination of AMAH Capture Efficiency

To test the microreactor for capturing trace levels of carbonyl compounds, a solution of acetaldehyde, acetone or 2-butanone in methanol (7.67×10^{-7} to 7.67×10^{-10} mol) was injected to a 1 liter air Tedlar bag. The vapor-filled Tedlar bag then was connected to the preconcentration setup as shown in Figure 2.2 before a vacuum pump was used to pull the gaseous vapor from the Tedlar bag through the closed microreactor

at a flow rate of 3.5 mL/min. The microreactor then was disconnected from the system after the air sample in the bag had been completely evacuated.

The reacted AMAH adduct and unreacted AMAH were eluted from the closed microreactor by flowing 100 μ L methanol from one slightly pressurized vial through the microreactor, and into an empty collecting sample vial. An internal reference for FT-ICR-MS analysis was established by adding a solution of 1.53×10^{-8} mol of AMAH-acetone- d_6 adduct in methanol to each sample of eluent. The resulting solutions were directly injected into the FT-ICR-MS for analysis without any further process.

5.2.4. FT-ICR-MS Instrumentation

The methanol-eluted mixtures of AMAH-VOC adducts were analyzed on a hybrid linear ion trap- FT-ICR-MS instrument (Finnigan LTQ-FT, Thermo Electron, Bremen, Germany) equipped with a TriVersa NanoMate ion source (Advion BioSciences, Ithaca, NY) with an electrospray chip (nozzle inner diameter 5.5 μ m). The TriVersa NanoMate was operated in positive ion mode by applying 2.0 kV with no head pressure. Initially, low-resolution MS scans were acquired for 1 min to ensure the stability of ionization, after which high mass accuracy data were collected using the FT-ICR analyzer where MS scans were acquired for 8.5 min and at the target mass resolution of 100,000 at 800 m/z. AMAH and AMAH-adduct species were assigned on the basis of their accurate mass by first applying a small (typically <0.0005) linear correction based on the observed mass of the internal standard.

5.2.5. GC-MS Instrumentation

A Thermo Scientific GC/MS instrument equipped with an AI 1310 automatic sampler, a TRACE 1310 GC with a split/splitless injector and an ITQ 1100 series ion trap MS was used for analysis. The GC was fitted with an Agilent J&W DB-17ms column (30 m × 0.25 mm × 0.25 μm film thickness). The carrier helium flow rate was set to 1.5 mL/min. The injection port temperature was set to 280 °C and the initial column temperature was 50 °C for 1 minute, with a 12 °C/min ramp up to 290 °C and was held at 290 °C for 5 minutes. The total running time was 26 minutes. The samples were split injected with split flow 15 ml/min and split ratio of 10.

Carbonyl adduct standards for retention time determination were prepared by individually reacting excess AMA (5.1×10^{-7} mol) with commercially available aldehydes or ketones (3.5×10^{-7} mol) in a 1:1 mixture of acetonitrile:MTBSTFA (v/v) (100 μL). MTBSTFA reacted with the AMA-3-hydroxy-2-butanone and AMA-hydroxyacetaldehyde adducts to form AMA-3-(*tert*-butyldimethylsilyloxy)-2-butanone (AMA-3-TBSO-2-butanone) and AMA-(*tert*-butyldimethyl-silyloxy)acetaldehyde (AMA-TBSO-acetaldehyde), respectively for GC-MS analysis.

5.2.6. Synthesis of AMAH

2-(2-Morpholinoethoxy)isoindoline-1,3-dione. By analogy to our published method¹³ for synthesis of quaternary ammonium aminoxy compounds as well as to a literature procedure,¹⁴ we prepared AMAH as follows: diisopropyl azodicarboxylate (DIAD) (3.60

mL, 18.3 mmol) was added dropwise to a stirred solution of 2-(4-morpholinyl) ethanol (2.00 g, 15.3 mmol), *N*-hydroxyphthalimide (2.98 g, 18.3 mmol), and triphenylphosphine (4.80 g, 18.3 mmol) in dry THF (95 mL) at 0 °C under nitrogen. The resulting solution was allowed to warm to rt and then stirred. After 16 h, the THF was removed *in vacuo* and the resulting oil was dissolved in EtOAc (150 mL) and washed with sat. NaHCO₃ (3 x 50 mL) and brine (50 mL). The organic phase was reduced to 50 mL *in vacuo* followed by the addition of cold 5% HCl to pH 3. The aqueous phase was separated, washed with Et₂O (3 x 20 mL), and then basified with sat. NaHCO₃ to pH 7.5. The aqueous phase then was extracted with CHCl₃ (3 x 50 mL). The combined organic extract was dried (Na₂SO₄), filtered, and the solvent was removed *in vacuo* to afford 2-(2-morpholinoethoxy)isoindoline-1,3-dione as a light yellow solid (3.67 g, 87%); mp, 78-79 °C; TLC, *R_f* 0.37 (EtOAc); ¹H NMR (CDCl₃) δ 2.55 (s, 4H), 2.84 (t, *J* = 4.8 Hz, 2 H), 3.60 (t, *J* = 3.8 HZ, 4 H), 4.36 (t, *J* = 5 Hz, 2 H), 7.74-7.76 (m, 2 H), 7.82-7.84 (m, 2 H); ¹³C NMR (CDCl₃) δ 53.8, 57.2, 66.9, 74.2, 123.7, 129.2, 134.7, 163.7.

AMAH

4-(2-Aminoxyethyl)-morpholin-4-ium chloride (AMAH). Hydrazine monohydrate (527 μL, 10.9 mmol) was added to a stirred solution of 2-(2-morpholinoethoxy)isoindoline-1,3-dione (735 mg, 2.66 mmol) in CH₂Cl₂ (11 mL) at rt. After stirring for 20 h, the suspension was filtered through a fritted glass funnel and the cake was washed with ample CH₂Cl₂. The filtrate and combined CH₂Cl₂ washes were concentrated *in vacuo* and the residue was distilled using a Kugelrohr apparatus (10 Torr,

150 °C). The distillate was dissolved in Et₂O (11 mL) and gaseous HCl was bubbled into the solution. The acidic solution was stirred at rt for 1 h, and then dried *in vacuo* to provide 4-(2-aminooxyethyl)-morpholin-4-ium chloride (AMAH, 486 mg, 100% yield) as a white solid; mp, 148-151 °C; IR ν (cm⁻¹) 902, 1030, 1444, 2022, 2640, 3418; ¹H NMR (DMSO-*d*₆) δ 3.29 (s, 4 H), 3.47 (t, *J* = 4.4 Hz, 2 H), 3.89 (t, *J* = 4.4 Hz, 4 H), 4.47 (t, *J* = 4.6 Hz, 2 H), 11.18 (br s, 1H); ¹³C NMR (DMSO-*d*₆) δ 51.2, 53.5, 63.1, 68.2.

5.2.7. Procedure for Neutralization of AMAH-adducts

A 35 μ L aliquot of the methanol AMAH-adduct mixture was transferred to a 200 μ L insert containing 2 mg of poly(4-vinylpyridine) (PVP) for the neutralization of AMAH-adducts to AMA-adducts. After shaking the vial for 30 seconds, the vial was centrifuged at 1000 rpm for 5 minutes to settle the PVP. A 2 μ L aliquot was taken from the supernatant and directly injected into the GC-MS.

5.2.8. Synthesis of ADMH

2-(2-(Dimethylamino)ethoxy)-2,3-dihydro-1H-indole-1,3-dione was synthesized following a procedure described by Biswas *et al.*⁴

ADMH

***O*-[2-(Dimethylamino)ethyl]hydroxylamine hydrochloride (ADMH).** Methylhydrazine (247 μL , 4.70 mmol) was added to a solution of 2-[2-(dimethylamino)ethoxy]-2,3-dihydro-1*H*-isoindole-1,3-dione (1.02 g, 4.35 mmol) in dry CH_2Cl_2 (14 mL) at 0 $^\circ\text{C}$ and was stirred for 4.5 h. At completion, the solvent was removed by distillation and the residue was Kugelrohr distilled at atmospheric pressure. A small amount of oxime was present, so the distilled product was dissolved in 6 *M* aq. HCl (5 mL) and refluxed for 22 h. The majority of the water was removed by distillation and the product was finally azeo-dried with hexanes. Isopropanol was added to the remaining residue and the solution was stirred until white crystal formation ceased. The crystals were collected by filtration, washed once with *i*-PrOH and dried under reduced pressure to yield *O*-[2-(dimethylamino)ethyl]hydroxylamine hydrochloride (ADMH, 224 mg, 37%) as a white crystal. ^1H NMR (DMSO- d_6 , 700 MHz) δ 2.79 (s, 6H), 3.43 (t, J = 4.6 Hz, 2H), 4.43 (t, J = 4.9 Hz, 2H), 11.14, (br s, 3H); ^{13}C NMR (DMSO- d_6 , 176 MHz) δ 42.3, 53.7, 68.4; FT-ICR-MS calcd for $\text{C}_4\text{H}_{13}\text{N}_2\text{O}^+$ [$\text{M} + \text{H}$] $^+$ m/z 105.1022, found.

5.2.9. Synthesis of AAn

9-Anthracenemethanol. Sodium borohydride (275 mg, 7.27 mmol) was added to a solution of 9-anthracenecarboxaldehyde (1.02 g, 4.93 mmol) in EtOH (30 mL) at 0 $^\circ\text{C}$.

The reaction was then heated to 55 °C for 3.5 h. After cooling to rt, the reaction was quenched with sat NH₄Cl (50 mL) and extracted three times with CH₂Cl₂. The combined organic phases were dried over Na₂SO₄, filtered and concentrated *in vacuo* to give a crude material of 9-anthracenemethanol (yellow crystal, 1.07 g) that was used in the next step without further purification. *R_f* 0.49 (2:23, EtOAc:CH₂Cl₂).

2-(Anthracen-9-ylmethoxy)-2,3-dihydro-1H-isindole-1,3-dione. DIAD (1.26 mL, 6.40 mmol) was added dropwise to a solution of crude 9-anthracenemethanol (1.03 g, 4.92 mmol), *N*-hydroxyphthalimide (942 mg, 6.40 mmol), and PPh₃ (1.68 g, 6.40 mmol) in dry THF (25 mL) at 0 °C and the reaction was stirred overnight. The solvent was then removed and the residue was diluted with CH₂Cl₂. The solution was then washed twice with sat. NaHCO₃ and the aqueous phase was extracted twice with CH₂Cl₂. The combined organic phases were washed with brine, dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, CH₂Cl₂) to give 2-(anthracen-9-ylmethoxy)-2,3-dihydro-1H-isindole-1,3-dione as a yellow solid (1.68 g, 96%). *R_f* 0.73 (1:19, EtOAc:CH₂Cl₂); ¹H NMR (400 MHz, DMSO-d₆) δ 6.18 (s, 2H), 7.59 (t, *J* = 7.6 Hz, 2H), 7.71 (t, *J* = 7.6 Hz, 2H), 7.92-7.94 (m, 4H), 8.17 (d, *J* = 8.4 Hz, 2H), 8.66 (d, *J* = 8.8 Hz, 2H), 8.78 (s, 1H); ¹³C NMR (100 MHz,

DMSO-d₆) δ 71.3, 123.3, 124.0, 124.2, 125.4, 127.1, 128.8, 128.9, 129.8, 130.8, 131.2, 134.9, 163.4.

AAn

***O*-(Anthracen-9-ylmethyl)hydroxylamine (AAn).** Hydrazine monohydrate (343 μ L, 7.08 mmol) was added to a suspension of 2-(anthracen-9-ylmethoxy)-2,3-dihydro-1*H*-isoindole-1,3-dione (531 mg, 1.50 mmol) in EtOH (36 mL) at 0 °C. After the addition was complete, the ice bath was removed and 2-(anthracen-9-ylmethoxy)-2,3-dihydro-1*H*-isoindole-1,3-dione slowly went into solution before a white precipitate began to drop from the solution. After 5 h the white solids were filtered, washed with CH₂Cl₂, and the filtrate was concentrated *in vacuo*. Dilute HCl (30 mL, 10%) was added to the residue and stirred for 10 minutes. The solution was washed once with EtOAc before being basified with sat. NaHCO₃. The basic solution was extracted three times with CHCl₃, the combined organic phase was dried over Na₂SO₄, filtered and concentrated *in vacuo* to give *O*-(anthracen-9-ylmethyl)hydroxylamine (AAn, 200 mg, 60%) as yellow crystals. *R_f* 0.35 (1:19, EtOAc:CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 5.73 (s, 2H), 7.48 (dd, *J* = 7.2 Hz, 2H), 7.57 (dd, *J* = 6.4, 8.8 Hz, 2H), 8.02 (d, *J* = 8.0 Hz, 2H), 8.44-8.47 (m, 3H); ¹³C NMR (100 MHz, DMSO-d₆) δ 70.0, 124.6, 125.2, 126.4, 127.9, 128.8, 129.2, 131.4, 131.6.

5.3. EXPERIMENTAL PROCEDURES FROM CHAPTER 3

5.3.1. First Generation

2-(Oct-3-yn-1-yl)-2,3-dihydro-1H-isoindole-1,3-dione. DIAD (1.84 mL, 9.34 mmol) was added to a solution of oct-3-yn-1-ol (907 mg, 7.18 mmol), phthalimide (1.37 g, 9.34 mmol) and triphenylphosphine (2.45 g, 9.34 mmol) in dry THF (36 mL) at 0 °C and stirred overnight. The solution was then concentrated *in vacuo* and diluted with EtOAc (50 mL). The solution was washed with NaHCO₃ (3 x 40 mL) and the combined aqueous layers were extracted with EtOAc (20 mL). The combined organics were washed with brine (45 mL), dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 1:19 to 1:4, EtOAc:hexanes gradient) to give 2-(oct-3-yn-1-yl)-2,3-dihydro-1H-isoindole-1,3-dione (1.77 g, 97%) as a white solid. *R_f* 0.78 (1:1, EtOAc:hexanes); ¹H NMR (500 MHz, CDCl₃) δ 0.76 (t, *J* = 7.3 Hz, 3H), 1.20-1.25 (m, 2H), 1.29-1.32 (m, 2H), 2.00-2.03 (m, 2H), 2.50-2.53 (m, 2H), 3.78 (t, *J* = 7.3 Hz, 2H), 7.66-7.68 (m, 2H), 7.78-7.80 (m, 2H); ¹³C NMR (100 MHz, CDCl₃) δ 13.5, 18.2, 18.6, 21.8, 30.8, 37.1, 75.8, 82.3, 123.1, 132.0, 133.9, 167.9.

Oct-3-yn-1-amine. Hydrazine monohydrate (1.68 mL, 34.6 mmol) was added to a solution of 2-(oct-3-yn-1-yl)-2,3-dihydro-1H-isoindole-1,3-dione (1.77 g, 6.93 mmol) in 1:1 CH₂Cl₂:EtOH (5 mL) at 0 °C with stirring. The reaction was allowed to reach room

temperature and stir overnight. The white precipitate was removed through filtration and the filter cake was washed with ample CH_2Cl_2 and the filtrate was concentrated *in vacuo*. The crude material was purified by column chromatography (SiO_2 , 1:1:98 to 10:1:89 MeOH: NH_4OH : CH_2Cl_2 gradient) to give oct-3-yn-1-amine (555 mg, 64%) as a yellow oil. R_f 0.46 (10:1:89, MeOH: NH_4OH : CH_2Cl_2); ^1H NMR (500 MHz, CDCl_3) δ 0.82 (t, J = 7.3 Hz, 3H), 1.29-1.34 (m, 2H), 1.36-1.39 (m, 2H), 1.72 (br s, 2H), 2.06-2.09 (m, 2H), 2.20-2.23 (m, 2H), 2.71 (t, J = 6.3 Hz, 2H); ^{13}C NMR (100 MHz, CDCl_3) δ 13.6, 18.4, 22.0, 23.9, 31.2, 41.5, 77.8, 81.9.

Bis(dimethylsilyl)(oct-3-yn-1-yl)amine (4). *n*-BuLi (3.15 mL 1.6 M in hexanes, 5.04 mmol) was added dropwise to a solution of oct-3-yn-1-amine (517 mg, 4.13 mmol) in dry THF (21 mL) at -78 °C and stirred for 0.5 h, then warmed to -40 °C and stirred for another 0.5 h. After cooling the solution back to -78 °C, chlorodimethylsilane (504 μL , 4.54 mmol) was added and the solution was warmed to -40 °C and stirred for 1 h. The solution was cooled back to -78 °C and a second portion of *n*-BuLi (3.44 mL 1.6 M in hexanes, 5.50 mmol) was added dropwise and stirred for 1 h after returning to -40 °C. After cooling back to -78 °C the second portion of chlorodimethylsilane (550 μL , 4.95 mmol) was added and the solution was stirred overnight. Hexanes (33 mL) was added to the reaction to precipitate LiCl, filtered and concentrated *in vacuo*. The crude was purified by Kugelrohr distillation to provide **4** (731 mg, 73%) as a colorless oil. ^1H NMR

(400 MHz, CDCl₃) δ 0.16 (s, 12H), 0.90 (t, J = 7.2 Hz, 3H), 1.38-1.46 (m, 4H), 2.13 (t, J = 6.8 Hz, 2H), 2.19 (t, J = 8 Hz, 2H), 2.95 (t, J = 7.8 Hz, 2H), 4.43 (t, J = 3.4 Hz, 2H); ¹³C NMR (100 MHz, CDCl₃) δ -0.3, 13.8, 18.7, 22.2, 24.1, 31.4, 46.1, 78.1, 81.6.

2-[(3E)-2,2-Dimethyl-1,2-azasilolidin-3-ylidene]hexan-1-ol (5). Bis(dimethylsilyl)(oct-3-yn-1-yl)amine (142 mg, 0.59 mmol) in toluene (10 mL) was added to a solution of cat. Rh₄(CO)₁₂ (2 mg, 0.0025 mmol) in toluene (5 mL). The autoclave was then sealed and purged with CO before adjusting the pressure to 10 atm with CO gas. The reactor was then heated to 60 °C for 14 h, at which point the pressure was relieved and the reaction solution was poured into a solution of NaBH₄ (189 mg, 5.0 mmol) in MeOH (5 mL) at 0 °C and stirred for 10 min. The reaction was quenched with NH₄Cl (20 mL) and extracted with Et₂O (3 x 10 mL). The combined organics were dried over K₂CO₃, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 1:1:98 to 5:1:94 MeOH:NH₄OH:CH₂Cl₂ gradient) to give **5** (83 mg, 66%). R_f 0.57 (10:1:89, MeOH:NH₄OH:CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 0.23 (s, 6H), 0.90 (t, J = 6.6 Hz, 3H), 1.25-1.36 (m, 4H), 1.56 (br s, 1H), 2.14 (t, J = 7.2 Hz, 2H), 2.34 (t, J = 6.6 Hz, 2H), 2.76 (br s, 2H), 4.48 (s, 2H); ¹³C NMR (100 MHz, CDCl₃) δ 1.4, 14.1, 23.0, 27.9, 30.9, 31.9, 42.3, 74.1, 130.3, 155.0.

5.3.2. Synthesis of 2-(9-Anthracenyl)ethanol⁵ (25)

(E/Z)-9-(2-Methoxyvinyl)anthracene. (Methoxymethyl)triphenylphosphonium chloride (13.5 g, 39.5 mmol) was suspended in dry THF (105 mL) under nitrogen with stirring to which KHMDS (68.5 mL of 0.5 M solution in toluene, 34.2 mmol) was added dropwise via syringe at room temperature and stirred for 1 hour. The addition of KHMDS turned the white suspension to a dark red solution. The solution was then cooled to -78 °C and a solution of 9-anthraldehyde (5.43 g, 26.3 mmol) in dry THF (20 mL) was added dropwise. The reaction was allowed to warm to room temperature and was stirred overnight. The reaction solution was then poured into water (75 mL) and EtO₂ (50 mL) was added. After separation, the aqueous phase was extracted with EtO₂ (75 mL) and CH₂Cl₂ (75 mL). The combined organics were then dried over Na₂SO₄, filtered, and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 1:1 CH₂Cl₂:hexanes) to give a dark orange solid (E/Z)-9-(2-methoxyvinyl)anthracene (6.05 g, E/Z 1:1, 98%). *R_f* 0.6 (1:1, CH₂Cl₂:hexanes); ¹H NMR (400 MHz, CDCl₃) *E* isomer δ 3.94 (s, 3H), 6.43 (d, *J* = 13.2 Hz, 1H), 6.77 (d, *J* = 13.2 Hz), 7.45-7.52 (m, 4H), 7.99-8.00 (m, 2H), 8.25 (d, *J* = 9.2 Hz), 8.37-8.41 (m, 2H); ¹³C NMR (100 MHz, CDCl₃) *E* isomer δ 56.7, 99.1, 125.3, 125.9, 126.5, 126.9, 128.7, 129.9, 130.8, 131.8, 153.1.

2-(Anthracen-9-yl)acetaldehyde. (*E/Z*)-9-(2-methoxyvinyl)anthracene (6.05 g, 25.8 mmol) was dissolved in THF (129 mL) with stirring. Aqueous 2 M HCl solution (51.6 mL, 103.2 mmol) was added and the reaction solution was heated to 60 °C and stirred overnight. The reaction was then quenched with aqueous NaHCO₃ (125 mL), extracted with EtO₂ (3 x 80 mL), and washed with brine (100 mL). The resulting solution was dried over Na₂SO₄, filtered and concentrated *in vacuo* to give a crude material 2-(anthracen-9-yl)acetaldehyde as orange crystals that were used in the next step without further purification. *R_f* 0.34 (1:1 CH₂Cl₂:hexanes); ¹H NMR (700 MHz, CDCl₃) δ 4.70 (d, *J* = 2.8 Hz, 2H), 7.50-7.52 (m, 2H), 7.56-7.58 (m, 2H), 8.05 (d, *J* = 8.4 Hz, 2H), 8.17 (d, *J* = 8.4 Hz, 2H), 8.48 (s, 1H); ¹³C NMR (176 MHz, CDCl₃) δ 44.5, 122.0, 122.4, 123.8, 125.2, 126.4, 127.9, 129.2, 130.0, 195.1.

25

2-(Anthracen-9-yl)ethanol (25). Crude 2-(anthracen-9-yl)acetaldehyde (5.68 g, 25.8 mmol) was dissolved in 5:1 THF:MeOH (129 mL) with stirring at room temperature. NaBH₄ (1.17 g, 31.0 mmol) was added portion-wise to the reaction solution and allowed to stir for 12 h. The reaction was quenched with aqueous NH₄Cl (70 mL) and extracted

with EtO₂ (3 x 50 mL). The combined organics were washed with brine (75 mL), dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 0:100 to 6:94 EtOAc:CH₂Cl₂ gradient) to give a yellow solid **25** (4.61 g, 80% over two steps). *R_f* 0.45 (5:95, EtOAc:CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 1.56 (s, 1H), 3.94 (t, *J* = 7.0 Hz, 2H), 4.09 (t, *J* = 7.0 Hz, 2H), 7.45-7.55 (m, 4H), 8.01 (d, *J* = 8.4 Hz, 2H), 8.33 (d, *J* = 8.8 Hz, 2H), 8.39 (s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 31.3, 63.6, 124.5, 125.2, 126.0, 126.7, 129.4, 130.4, 130.6, 131.8.

5.3.3. Synthesis of Amino Esters and Amide (Scheme 3.3)

12.1-3

5-((*tert*-Butoxycarbonyl)amino)pentanoic acid (12.2). 5-aminopentanoic acid (1.99 g, 17.0 mmol) was dissolved in a 2:1 mixture of 1,4-dioxane:H₂O (51 mL) and cooled to 0 °C. A 1 M solution of NaOH (0.68 g, 17.1 mmol) was added, followed by the addition of di-*tert*-butyl dicarbonate (4.10g, 18.8 mmol). After 18 h, the dioxane was removed *in vacuo* and the remaining aqueous layer was washed with EtOAc (19 mL). The aqueous phase was then acidified to pH ~3 with 1 M HCl and extracted with EtOAc (3 x 19 mL). The combined organics were dried over MgSO₄, filtered, and concentrated *in vacuo* to give a crude material **12.2** (white crystals) which were used in the next step without further purification. ¹H NMR (400 MHz, CDCl₃) δ: 1.43 (s, 9H), 1.52 (dt, *J* = 7.2 Hz, 2H), 1.65 (dt, *J* = 7.4 Hz, 2H), 2.36 (t, *J* = 7.2 Hz, 2H), 4.61 (br s, 1H). ¹³C NMR (100 MHz, CDCl₃) δ: 22.0, 28.6, 29.6, 33.7, 40.4, 79.5, 156.3, 178.9.

6-((*tert*-Butoxycarbonyl)amino)hexanoic acid (12.1). ^1H NMR (400 MHz, CDCl_3) δ : 1.31-1.52 (m, 13H), 1.63 (dt, $J = 7.6$ Hz, 2H), 2.33 (t, $J = 7.4$ Hz, 2H), 3.08 (br s, 2H), 4.60 (br s, 1H), 10.44 (br s, 1H). ^{13}C NMR (100 MHz, CDCl_3) δ : 24.5, 26.4, 28.6, 29.9, 34.1, 40.6, 79.6, 156.1, 179.2.

4-((*tert*-Butoxycarbonyl)amino)butanoic acid (12.3). ^1H NMR (400 MHz, CDCl_3) δ : 1.43 (s, 9H), 1.80 (dt, $J = 7.2$ Hz, 2H), 2.38 (t, $J = 7.0$ Hz, 2H), 3.16 (br s, 2H), 4.72 (br s, 1H), 9.34 (br s, 1H). ^{13}C NMR (100 MHz, CDCl_3) δ : 25.3, 28.6, 31.5, 40.0, 79.8, 156.4, 178.5.

13.1: $n = 1$

13.2: $n = 2$

13.3: $n = 3$

5-(Allyl(*tert*-butoxycarbonyl)amino)pentanoic acid (13.2). Boc-protected amine **12.2** (4.65 g, 21.4 mmol) was added to a slurry of 60% NaH (4.28 g, 107 mmol) in dry THF (140 mL) at 0 °C. After one-hour of stirring, allyl bromide (5.56 mL, 64.2 mmol) was added dropwise. After 24 h, the reaction mixture was cooled to 0 °C and quenched with water until the reaction became transparent. The reaction was acidified to pH ~3 by addition of 1 M HCl and the layers were separated. The aqueous phase was extracted with EtOAc (2 x 30 mL) and the combined organic phase was washed with brine (50 mL), dried over Na_2SO_4 , filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO_2 , 1:1 EtOAc:hexanes) to give **13.2** as an oil (4.77 g, 87%); R_f 0.36 (1:1 EtOAc:hexanes); ^1H NMR (400 MHz, CDCl_3) δ 1.43 (s, 9H), 1.51-1.64 (m, 4H), 2.35 (t, $J = 7.0$ Hz, 2H), 3.17 (br s, 2H), 3.78 (br s, 2H), 5.09 (d, $J =$

11.6 Hz, 2H), 5.70-5.78 (m, 1H); ^{13}C NMR (100 MHz, CDCl_3) δ 22.1, 27.8, 28.6, 33.9, 46.2, 49.7, 79.9, 116.5, 134.4, 155.8, 179.6; FT-ICR-MS calcd for $\text{C}_{13}\text{H}_{22}\text{NO}_4^-$ [$\text{M} - \text{H}$] $^-$ m/z 256.1554, found 256.1555.

4-(Allyl(*tert*-butoxycarbonyl)amino)butanoic acid (13.1). ^1H NMR (400 MHz, CDCl_3) δ 1.44 (s, 9H), 1.83 (dt, 2H), 2.34 (t, $J = 7.2$ Hz, 2H), 3.24 (br s, 2H), 3.79 (br s, 2H), 5.08-5.12 (m, 2H), 5.71-5.80 (m, 1H); ^{13}C NMR (100 MHz, CDCl_3) δ 23.5, 28.6, 31.4, 45.8, 49.7, 80.1, 116.7, 134.1, 155.9, 178.9; FT-ICR-MS calcd for $\text{C}_{12}\text{H}_{20}\text{NO}_4^-$ [$\text{M} - \text{H}$] $^-$ (m/z) 242.1398, found 242.1398.

6-(Allyl(*tert*-butoxycarbonyl)amino)hexanoic acid (13.3). ^1H NMR (400 MHz, CDCl_3) δ 1.30 (dt, $J = 7.6$ Hz, 2H), 1.43 (s, 9H), 1.83 (dt, $J = 7.6$ Hz, 2H), 1.63 (dt, $J = 7.6$ Hz, 2H), 2.33 (t, $J = 7.4$ Hz, 2H), 3.15 (t, $J = 7.0$ Hz, 2H), 3.77 (br s, 2H), 5.07-5.11 (m, 2H), 5.70-5.80 (m, 1H), 10.02 (br s, 1H); ^{13}C NMR (100 MHz, CDCl_3) δ 24.6, 26.4, 28.1, 28.6, 34.2, 46.6, 49.7, 79.7, 116.3, 134.5, 155.8, 179.7; FT-ICR-MS calcd for $\text{C}_{14}\text{H}_{24}\text{NO}_4^-$ [$\text{M} - \text{H}$] $^-$ (m/z) 270.1711, found 270.1710.

After stirring 1h, the volatiles were removed *in vacuo* to afford the TFA salt of **9** (15 mg, 72%) as an oil; 1H NMR (400 MHz, $CDCl_3$) δ 1.97 (t, J = 6.4 Hz, 2H), 2.29 (t, J = 6.4 Hz, 2H), 2.97 (br s, 2H), 3.54 (br s, 2H), 3.60 (q, J = 7.2 Hz, 2H), 3.81 (t, J = 7.8 Hz, 2H), 5.40-5.46 (m, 2H), 5.84-5.93 (m, 1H), 6.81 (s, 1H), 7.42-7.52 (m, 4H), 7.97 (d, J = 8.0 Hz, 2H), 8.28 (d, J = 8.8 Hz, 2H), 8.34 (s, 1H), 9.81 (br s, 2H); ^{13}C NMR (100 MHz, $CDCl_3$) δ 21.9, 27.7, 33.7, 40.7, 46.7, 50.0, 124.0, 124.3, 125.2, 126.2, 126.7, 127.9, 129.4, 130.3, 130.8, 131.7, 173.0; FT-ICR-MS calcd for $C_{23}H_{27}N_2O^+$ $[M + H]^+$ (m/z) 347.2118, found 347.2143.

5.3.4. Synthesis of Amino Carbonates (Scheme 3.4)

15.1-2

***tert*-Butyl (2-hydroxyethyl)carbamate (15.1).** Et_3N (2.51 mL, 18.0 mmol) was added to a solution of 2-ethanolamine (1.02 g, 16.7 mmol) in dry CH_2Cl_2 (33 mL) with stirring at 0 °C. Boc_2O (3.93 g, 18.0 mmol) was then added to the reaction, turning the solution to an opaque white color that slowly cleared as the reaction proceeded. The reaction was stirred for 19 h and then was quenched with sat. NH_4Cl (30 mL) and the aqueous phase was extracted with CH_2Cl_2 (2 x 20 mL). The combined organics were washed with brine (30 mL), dried over Na_2SO_4 , filtered and concentrated *in vacuo* to give crude **15.1** as a

light yellow oil which was used in the next step without further purification. R_f 0.38 (1:19, MeOH:CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 1.40 (s, 9H), 2.86 (br s, 1H), 3.23 (br s, 2H), 3.63 (br s, 2H), 5.03 (br s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 28.6, 43.3, 62.6, 79.8, 157.0.

***tert*-Butyl (3-hydroxypropyl)carbamate (15.2).** ¹H NMR (400 MHz, CDCl₃) δ 1.42 (s, 9H), 1.64 (dt, J = 5.8 Hz, 2H), 3.18 (br s, 1H), 3.25 (dt, J = 6.4, 5.6 Hz, 2H), 3.63 (br s, 2H), 4.87 (br s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 28.6, 33.0, 37.1, 59.4, 79.8, 157.3.

***tert*-Butyl (2-((*tert*-butyldimethylsilyl)oxy)ethyl)carbamate.** TBSCl (3.06 g, 20.3 mmol) was added to a solution of **1.1** (2.70 g, 16.7 mmol), Et₃N (2.85 mL, 20.3 mmol) and imidazole (3.14 g, 46.1 mmol) in dry CH₂Cl₂ (40 mL) with stirring at 0 °C. After 23 h, the reaction was quenched with water (25 mL) and the aqueous phase was extracted with CH₂Cl₂ (2 x 10 mL). The combined organics were washed with sat. NH₄Cl, dried over Na₂SO₄, filtered and condensed *in vacuo*. The crude material was purified by column chromatography (SiO₂, 3:7 EtOAc:hexanes) to give *tert*-butyl (2-((*tert*-butyldimethylsilyl)oxy)ethyl)carbamate (4.52 g, 98%) as a colorless oil. R_f 0.67 (1:1, EtOAc:hexanes); ¹H NMR (400 MHz, CDCl₃) δ 0.06 (s, 6H), 0.89 (s, 9H), 1.44 (s, 9H), 3.23 (br s, 2H), 3.65 (br s, 2H), 4.84 (br s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ -5.1, 18.5, 26.1, 28.6, 43.1, 62.5, 79.4, 156.2.

2-(Anthracen-9-yl)ethyl 3-((allyl)amino)ethyl carbonate (7.1, TFA salt). Trifluoroacetic acid (0.50 mL, 6.53 mmol) was added to a solution of Boc-protected **7.1** (13 mg, 0.030 mmol) in dry CH_2Cl_2 (0.50 mL) at 0 °C. After stirring 1h, the volatiles were removed *in vacuo* to afford the TFA salt of **2.1** (14 mg, 100%) as an oil; ^1H NMR (400 MHz, CDCl_3) δ 3.24 (t, $J = 4.8$ Hz, 2H), 3.62-3.64 (m, 2H), 4.00 (t, $J = 8.0$ Hz, 2H), 4.44-4.48 (m, 4H), 5.42-5.46 (m, 2H), 5.85-5.96 (m, 1H), 7.43-7.54 (m, 4H), 7.99 (d $J = 8.0$ Hz, 2H), 8.26 (d, $J = 8.8$ Hz, 2H), 8.37 (s, 1H); ^{13}C NMR (100 MHz, CDCl_3) δ 27.2, 45.3, 50.2, 63.0, 68.0, 124.0, 124.6, 125.2, 126.4, 127.2, 127.6, 129.5, 130.5, 131.7, 134.3, 154.9; FT-ICR-MS calcd for $\text{C}_{22}\text{H}_{24}\text{NO}_3^+ [\text{M} + \text{H}]^+$ (m/z) 350.1751, found 350.1758.

5.3.5. Synthesis of Carbamate (Scheme 3.5)

18

tert-Butyl (2-aminoethyl)carbamate (18). Ethylene diamine (9.2 mL, 138 mmol) was added dropwise via syringe to dry CH₂Cl₂ (82 mL) at 0 °C with stirring. A solution of Boc₂O (5.60 g, 25.7 mmol) in dry CH₂Cl₂ (76 mL) was added dropwise over 8 h with continued chilling. The reaction was allowed to stir overnight to form a colorless solution with clumps of white solids. The solids were filtered off and the filter cake was washed with CH₂Cl₂. The filtrate was condensed *in vacuo*, and then poured into NaHCO₃ solution (75 mL), which produced an exotherm, and shaken. The aqueous solution was extracted with CH₂Cl₂ (3 x 50 mL), and then the combined organics were dried over Na₂SO₄, filtered and condensed *in vacuo* to give crude **18** (turbid oil, 4.50 g) which was used in the next step without further purification. *R_f* 0.24 (10:2:88, MeOH:NH₄OH:CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 1.40 (s, 9H), 2.76 (br s, 2H), 3.14 (br s, 2H), 5.05 (br s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 28.5, 41.9, 43.4, 79.3, 156.4.

tert-Butyl N-(2-(1,3-dioxo-2,3-dihydro-1H-isoindol-2-yl)ethyl)carbamate. Phthalic anhydride (4.18 g, 28.2 mmol) was added to a solution of crude **18** (4.11 g, 25.7 mmol) in toluene (86 mL) with stirring and the reaction flask was fitted with a Dean-Stark apparatus. The mixture was heated to reflux for 6.5 h with the phthalic anhydride slowly

going into solution. After the heat was removed, the solution was allowed to stir overnight where a precipitate dropped out of solution. The mixture was washed with water (3 x 50 mL) and the combined aqueous phases were extracted with EtOAc (2 x 30 mL). The combined organics were washed with brine (50 mL), dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 1:19 to 1:1, EtOAc:CH₂Cl₂ gradient) to give *tert*-butyl *N*-(2-(1,3-dioxo-2,3-dihydro-1*H*-isoindol-2-yl)ethyl)carbamate (5.76 g, 77%) as a white solid. *R_f* 0.27 (1:19, EtOAc:hexanes); ¹H NMR (400 MHz, CDCl₃) δ 1.33 (s, 9H), 3.42 (br s, 2H), 3.82 (t, *J* = 5.6 Hz, 2H), 4.83 (br s, 1H), 7.70-7.72 (m, 2H), 7.82-7.86 (m, 2H); ¹³C NMR (100 MHz, CDCl₃) δ 28.4, 38.3, 39.8, 79.7, 123.5, 132.3, 134.2, 156.2, 168.7.

***tert*-Butyl allyl(2-(1,3-dioxoisindolin-2-yl)ethyl)carbamate (19).** *tert*-Butyl *N*-(2-(1,3-dioxo-2,3-dihydro-1*H*-isoindol-2-yl)ethyl)carbamate phthalimide (5.76 g, 19.8 mmol) was added to a slurry of NaH (1.59 g of 60% in mineral oil, 39.7 mmol) in dry THF (83 mL) at 0 °C. After stirring 1h, allyl bromide (2.23 mL, 25.8 mmol) was added dropwise. The slurry was stirred for three days and then quenched by addition into water (50 mL). The layers were separated and the aqueous phase was extracted with Et₂O (2 x 35 mL). The combined organic phase was washed with brine (50 mL), dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 1:19 EtOAc:CH₂Cl₂) to give **19** (3.77 g, 58%) as a white solid; *R_f*

0.55 (1:19 EtOAc:hexanes); mp = 73-76 °C; ¹H NMR (400 MHz, CDCl₃) δ 1.27 (s, 9H), 3.46 (br s, 2H), 3.81 (br s, 2H), 3.87 (br s, 2H), 5.01-5.13 (m, 2H), 5.71-5.77 (m, 1H), 7.70 (br s, 2H), 7.82 (br s, 2H); ¹³C NMR (100 MHz, CDCl₃) δ 28.2, 44.5, 49.3, 50.2, 80.1, 117.2, 123.4, 132.3, 133.9, 134.2, 155.3, 168.3.

2-(Anthracen-9-yl)ethyl N-(2-(allylamino)ethyl)carbamate (8, TFA salt). Hydrazine monohydrate (147 μ L, 3.03 mmol) was added to a solution of **19** (217 mg, 0.66 mmol) in 2:1 CH₂Cl₂:EtOH (6 mL) with stirring at 0 °C. The reaction was stirred for 18 h, allowing it to warm slowly to room temperature. The white precipitate was then filtered and the filter cake was washed with CH₂Cl₂ and concentrated *in vacuo*. The concentrate was diluted with CH₂Cl₂ and the precipitate was filtered, the cake washed with CH₂Cl₂ and concentrated *in vacuo* again to give the crude amine (light yellow oil, 122 mg, 92%) which was used in the next step without further purification. *R_f* 0.47 (10:2:88 MeOH:NH₄OH:CH₂Cl₂); ¹H NMR (500 MHz, CDCl₃) δ 1.40 (s, 2H), 1.43 (s, 9H), 2.79 (t, *J* = 5.0 Hz, 2H), 3.22 (br s, 2H), 3.81 (br s, 2H), 5.09-5.12 (m, 2H), 5.74-5.79 (m, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 28.6, 40.8, 50.1, 79.8, 116.4, 134.3, 156.0; FT-ICR-MS calcd for C₁₀H₂₁N₂O₂⁺ [M + H]⁺ (*m/z*) 201.1598, found 201.1599.

The amine (188 mg, 0.94 mmol) was added dropwise with stirring to a solution of ClC(O)OCH₂CH₂(9-anthracenyl) (303 mg, 1.06 mmol) in dry CH₂Cl₂ (3.5 mL) at 0 °C. After 10 minutes, Et₃N (148 μ L, 1.06 mmol) was added dropwise to the reaction, causing

the solution to darken. After stirring 17h, the reaction mixture was quenched by addition of sat. NH_4Cl (5 mL) and the aqueous phase was extracted with CH_2Cl_2 (5 mL). Combined organic phase was dried over Na_2SO_4 , filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO_2 , 5:1:4 CH_2Cl_2 :hexanes:EtOAc) to give Boc-protected **3** (171 mg, 41%) as a yellow gum; R_f 0.33 (1:19 EtOAc: CH_2Cl_2); FT-IR: 3449, 3058, 2971, 1724, 1514 cm^{-1} ; ^1H NMR (400 MHz, CDCl_3) δ 1.46 (s, 9H), 3.13 (br s, 2H), 3.36 (br s, 2H), 3.83 (br s, 2H), 3.97 (t, $J = 8.0$ Hz, 2H), 4.43 (br s, 2H), 5.10-5.15 (m, 2H), 5.75-5.81 (m, 1H), 7.44-7.48 (m, 2H), 7.52-7.56 (m, 2H), 8.00 (d, $J = 8.4$ Hz, 2H), 8.35-8.37 (m, 3H); ^{13}C NMR (100 MHz, CDCl_3) δ 28.1, 28.5, 40.5, 46.2, 50.6, 64.6, 80.3, 116.6, 124.4, 125.1, 126.1, 126.8, 129.3, 130.5, 131.7, 134.0, 155.3, 157.0; FT-ICR-MS calcd for $\text{C}_{27}\text{H}_{32}\text{N}_2\text{NaO}_4^+$ $[\text{M} + \text{Na}]^+ m/z$ 471.2254, found 471.2256.

Trifluoroacetic acid (0.50 mL, 6.53 mmol) was added to a solution of Boc-protected **8** (20 mg, 0.045 mmol) in dry CH_2Cl_2 (0.50 mL) at 0 °C. After stirring 1h, the volatiles were removed *in vacuo* to afford the TFA salt of **3** (18 mg, 88%) as an oil; ^1H NMR (400 MHz, CDCl_3) δ 3.09 (br s, 2H), 3.48-3.56 (m, 4H), 3.90 (t, $J = 8.0$ Hz, 2H), 4.36 (t, $J = 8.0$ Hz, 2H), 5.35-5.47 (m, 2H), 5.81-5.88 (m, 1H), 7.41-7.51 (m, 4H), 7.97 (d, $J = 8.4$ Hz, 2H), 8.27 (d, $J = 8.8$ Hz, 2H), 8.34 (s, 1H), 9.47 (br s, 2H); ^{13}C NMR (100 MHz, CDCl_3) δ 27.8, 37.8, 47.2, 50.2, 65.1, 124.3, 124.6, 125.2, 126.2, 126.9, 127.5, 129.4, 130.5, 131.7, 134.3, 157.5; FT-ICR-MS calcd for $\text{C}_{22}\text{H}_{25}\text{N}_2\text{O}_2^+$ $[\text{M} + \text{H}]^+ m/z$ 349.1910, found 349.1913

5.3.6. Synthesis of *gem*-Dimethylester (Scheme 3.6)

4,4-Dimethylcyclohexanone. 10 % Palladium on carbon (10 mg, 0.0094 mmol) was added to a solution of 4,4-dimethyl-2-cyclohexen-1-one (1.52 g, 12.2 mmol) in hexanes (15 mL). The atmosphere was purged with H₂ and sealed with a H₂ balloon attached. After 48 h the reaction was filtered through Celite and the filter cake was rinsed with hexanes. The filtrate was concentrated *in vacuo* to give 4,4-dimethylcyclohexanone (1.29 g white crystals, 83%) that was used in the next step without further purification. *R*_f 0.46 (1:3, EtOAc:Hexanes); ¹H NMR (400 MHz, CDCl₃) δ 1.09 (s, 6H), 1.66 (t, *J* = 6.0 Hz, 4H), 2.33 (t, *J* = 6.0 Hz, 4H); ¹³C NMR (100 MHz, CDCl₃) δ 27.7, 30.1, 38.2, 39.3, 212.8.

5,5-Dimethylazepan-2-one. A solution of 4,4-dimethylcyclohexanone (1.29 g, 10.2 mmol) in formic acid (10 mL) was added dropwise to a solution of hydroxylamine-*O*-sulfonic acid (1.73 g, 15.3 mmol) in formic acid (7 mL) and allowed to stir at rt for 15 min. The reaction flask was then heated to reflux. After 24 h, the reaction solution was cooled to rt and quenched with 10 *N* NaOH (40 mL). The aqueous mixture was extracted with chloroform (4 x 20 mL) and the combined organics were washed with water (2 x 10

mL) and brine (10 mL). The solution was dried over MgSO₄, filtered and concentrated *in vacuo* to give 5,5-dimethylazepan-2-one (1.06 g brown crystals, 73%) that was used in the next step without further purification. *R_f* 0.13 (EtOAc); ¹H NMR (400 MHz, CDCl₃) δ 0.97 (s, 6H), 1.42-1.44 (m, 2H), 1.48-1.50 (m, 2H), 2.39-2.42 (m, 2H), 3.15 (q, *J* = 5.2 Hz, 2H), 6.50 (br s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 29.0, 32.0, 33.0, 36.0, 38.3, 42.4, 179.1.

***tert*-Butyl 5,5-dimethyl-2-oxoazepane-1-carboxylate.** Di-*tert*-butyl dicarbonate (1.54 g, 7.01 mmol) and DMAP (856 mg, 7.01 mmol) were added to a solution of 5,5-dimethylazepan-2-one (899 mg, 6.37 mmol) in dry THF (16 mL) at rt. After purging the head-space with N₂, the reaction was heated to reflux. After 2.5 h the reaction was cooled to rt and the volatiles were removed *in vacuo* and the crude material was purified by column chromatography (SiO₂, 1:9 to 3:7, EtOAc:hexanes gradient) to give *tert*-butyl 5,5-dimethyl-2-oxoazepane-1-carboxylate as yellow crystals (1.05 g, 68%). *R_f* 0.68 (EtOAc); ¹H NMR (400 MHz, CDCl₃) δ 0.94 (s, 6H), 1.46-1.49 (m, 11H), 1.52-1.55 (m, 2H), 2.54-2.57 (m, 2H), 3.67-3.70 (m, 2H); ¹³C NMR (100 MHz, CDCl₃) δ 28.2, 28.8, 32.2, 35.2, 36.5, 41.8, 41.9, 83.0, 153.0, 175.8.

20

6-((*tert*-Butoxycarbonyl)amino)-4,4-dimethylhexanoic acid (20). Lithium hydroxide monohydrate (340 mg, 8.10 mmol) was added to a solution of *tert*-butyl 5,5-dimethyl-2-oxoazepane-1-carboxylate (888 mg, 3.68 mmol) in 2:1 THF:H₂O (18 mL) and the reaction was heated to 60 °C. After 4 h the reaction was cooled to rt and partitioned between Et₂O and H₂O and the organic layer separated. The aqueous phase was acidified to pH ~4 with 10 % HCl and extracted with EtOAc (3 x 15 mL). The combined organics were washed with brine (15 mL), dried over Na₂SO₄, filtered and concentrated *in vacuo* to give **20** (912 mg yellow crystals, 96%) that was used in the next step without further purification. *R*_f 0.29 (1:1, EtOAc:Hexanes with 0.5 % AcOH); ¹H NMR (400 MHz, CDCl₃) δ 1.37-1.43 (m, 11H), 1.58 (t, *J* = 8.4 Hz, 2H), 2.30 (t, *J* = 8.4 Hz, 2H), 3.11 (br s, 2H), 4.49 (br s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 26.9, 28.6, 29.5, 32.1, 36.6, 36.9, 41.6, 79.5, 156.2, 179.7.

21

6-(Allyl(*tert*-butoxycarbonyl)amino)-4,4-dimethylhexanoic acid (21). Amino acid **20** (912 mg, 3.52 mmol) was added to a slurry of 60% NaH (703 mg, 17.6 mmol) in dry THF (18 mL) at 0 °C. After stirring 1 h, allyl bromide (913 μL, 10.5 mmol) was added dropwise. After 24 h, the reaction mixture was cooled to 0 °C and quenched with water until the reaction became transparent. The reaction was acidified to pH ~3 by addition of

1 M HCl and the layers were separated. The aqueous phase was extracted with EtOAc (3 x 10 mL) and the combined organic phase was washed with brine (15 mL), dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 1:1 EtOAc:hexanes with 0.5% AcOH) to give **21** (712 mg, 68%) as a light yellow oil; *R_f* 0.43 (1:1 EtOAc:hexanes with 0.5% AcOH); ¹H NMR (400 MHz, CDCl₃) δ 0.88 (s, 6H), 1.39-1.44 (m, 11H), 1.56 (t, *J* = 8.0 Hz, 2H), 2.31 (t, *J* = 8.2 Hz, 2H), 3.14 (br s, 2H), 3.80 (br s, 2H), 5.11 (d, *J* = 11.6 Hz, 2H), 5.71-5.81 (m, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 26.8, 28.7, 29.5, 32.0, 36.4, 39.5, 42.8, 49.6, 79.8, 116.8, 134.6, 155.6, 180.2; FT-ICR-MS calcd for C₁₆H₂₈NO₄⁻ [M - H]⁻ *m/z* 298.2024, found 298.2024.

10

2-(Anthracen-9-yl)ethyl 4,4-dimethyl-6-(allylamino)-hexanoate (10, TFA salt). To a mixture of carboxylic acid **21** (370 mg, 1.24 mmol) and **25** (249 mg, 1.12 mmol) in dry CH₂Cl₂ (10 mL) at 0 °C was added DIC (264 μL, 1.69 mmol) and DMAP (pinch). After 16 h, the precipitated white solids were filtered and the filter cake was washed with CH₂Cl₂. The combined filtrate was condensed *in vacuo* and the crude material was purified by column chromatography (SiO₂, 0:100 to 1:19 EtOAc:CH₂Cl₂ gradient) to give Boc-protected *gem*-dimethyl ester **10** as a yellow oil (494 mg, 87%); *R_f* 0.58 (1:19 EtOAc:CH₂Cl₂); FT-IR 3058, 2963, 1728, 1684 cm⁻¹; ¹H NMR (400 MHz, CDCl₃) δ 0.87 (s, 6H), 1.39 (br s, 2H), 1.46 (s, 9H), 1.51 (t, *J* = 8.4 Hz, 2H), 2.28 (t, *J* = 8.2 Hz, 2H),

3.12 (br s, 2H), 3.81 (br s, 2H), 3.98 (t, $J = 7.8$ Hz, 2H), 4.48 (t, $J = 7.8$ Hz, 2H), 5.12 (d, $J = 11.6$ Hz, 2H), 5.73-5.82 (m, 1H), 7.46-7.49 (m, 2H), 7.53-7.57 (m, 2H), 8.02 (d, $J = 8.4$ Hz, 2H), 8.34 (d, $J = 9.2$ Hz, 2H), 8.39 (s, 1H); ^{13}C NMR (100 MHz, CDCl_3) δ 26.8, 27.5, 28.7, 29.8, 32.0, 36.6, 39.2, 42.8, 49.6, 53.6, 64.3, 79.6, 116.6, 124.3, 125.2, 126.2, 127.0, 129.5, 130.5, 131.7, 134.7, 155.5, 174.5; FT-ICR-MS calcd for $\text{C}_{32}\text{H}_{41}\text{NNaO}_4^+$ [$\text{M} + \text{Na}$] $^+$ m/z 526.2928, found 526.2927.

Trifluoroacetic acid (0.50 mL, 6.53 mmol) was added to a solution of Boc-protected **10** (11 mg, 0.022 mmol) in dry CH_2Cl_2 (0.50 mL) at 0 °C. After stirring 1h, the volatiles were removed *in vacuo* to afford the TFA salt of **10** (10 mg, 85%) as an oil; ^1H NMR (400 MHz, CDCl_3) δ 0.86 (s, 6H), 1.47 (t, $J = 8.4$ Hz, 2H), 1.58 (t, $J = 8.6$ Hz, 2H), 2.24 (t, $J = 8.4$ Hz, 2H), 2.88 (br s, 2H), 3.54 (br s, 2H), 3.96 (t, $J = 7.6$ Hz, 2H), 4.46 (t, $J = 8.0$ Hz, 2H), 5.40-5.47 (m, 2H), 5.84-5.94 (m, 1H), 7.44-7.56 (m, 4H), 8.00 (d, $J = 8.8$ Hz, 2H), 8.32 (d, $J = 9.2$ Hz, 2H), 8.38 (s, 1H), 9.47 (br s, 2H); ^{13}C NMR (100 MHz, CDCl_3) δ 26.5, 27.4, 29.4, 32.1, 36.1, 37.1, 43.2, 49.9, 64.4, 124.1, 124.3, 125.2, 126.2, 127.0, 127.9, 129.2, 129.5, 130.5, 131.7, 174.1; FT-ICR-MS calcd for $\text{C}_{27}\text{H}_{34}\text{NO}_2^+$ [$\text{M} + \text{H}$] $^+$ m/z 404.2584, found 404.2588.

5.3.7. Synthesis of *gem*-Dimethylcarbonate (Scheme 3.7)

Methyl 4-(allyl(*tert*-butoxycarbonyl)amino)-2,2-dimethylbutanoate (22). DIC (837 μL , 5.34 mmol) and DMAP (pinch) were added to a mixture of amino acid **16.2** (631 mg,

2.59 mmol) and dry MeOH (173 μ L, 4.28 mmol) in CH₂Cl₂ (32 mL) at rt. After 12 h the precipitated solids were filtered and the filter cake was washed with CH₂Cl₂. The combined filtrate was concentrated *in vacuo* and the resulting residue was purified by column chromatography (SiO₂, 1:1:8, EtOAc:THF:hexanes) to give methyl 4-(allyl(*tert*-butoxycarbonyl)amino)butanoate as a pale yellow oil (532 mg, 80%); *R_f* 0.65 (1:1:8, EtOAc:THF:hexanes); ¹H NMR (400 MHz, CDCl₃) δ 1.44 (s, 9H), 1.82 (dt, *J* = 7.0 Hz, 2H), 2.30 (t, *J* = 7.4 Hz, 2H), 3.20 (br s, 2H), 3.65 (s, 3H), 3.79 (br s, 2H), 5.10 (d, *J* = 12.8 Hz, 2H), 5.72-5.80 (m, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 23.7, 28.6, 31.4, 45.9, 49.7, 51.8, 79.8, 116.7, 134.3, 155.7, 173.8.

The methyl ester (532 mg, 2.06 mmol) was dissolved in dry THF (10 mL) and cooled to -78 °C with stirring. A solution of lithium bis(trimethylsilyl)amide (LiHMDS) in THF (6.20 mL of 1 *M* solution, 6.20 mmol) was added dropwise to the reaction solution. After stirring 1h, methyl iodide (772 μ L, 12.4 mmol) was added dropwise and the reaction was stirred overnight while slowly warming to rt. After 22 h, the reaction was cooled to 0 °C and quenched with water (5 mL), followed by 1 *M* HCl (5 mL). The phases were separated and the aqueous phase was extracted with Et₂O (3 x 15 mL). The combined organic phase was washed with NaHCO₃ (10 mL) and brine (10 mL) and then dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 1:4 EtOAc:hexanes) to give **22** (397 mg, 67%) as a yellow oil; *R_f* 0.48 (1:4, EtOAc:hexanes); ¹H NMR (400 MHz, CDCl₃) δ 1.18 (s, 6H), 1.44 (s, 9H), 1.74 (br s, 2H), 3.11 (br s, 2H), 3.65 (s, 3H), 3.79 (br s, 2H), 5.10 (d, *J* = 10.8 Hz, 2H), 5.70-5.79 (m, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 25.3, 28.6, 38.1, 41.1,

43.1, 49.4, 51.9, 79.7, 116.1, 134.2, 155.5, 178.0; FT-ICR-MS calcd for $C_{15}H_{27}NNaO_4^+$
[M + Na]⁺ *m/z* 308.1832, found 308.1836.

tert-Butyl allyl(4-hydroxy-3,3-dimethylbutyl)carbamate (23). LiBH₄ (45 mg, 2.08 mmol) was added to a solution of **22** (265 mg, 0.93 mmol) in dry THF (21 mL) at 0 °C. After 5 minutes of stirring the reaction was warmed to rt and stirred overnight. The reaction was then carefully quenched with NH₄Cl (25 mL) and extracted with Et₂O (3 x 10 mL). The combined organic phase was washed with brine (15 mL), dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 1:1 EtOAc:hexanes) to give **23** (175 mg, 73%) as a colorless oil; *R_f* 0.47 (1:1, EtOAc:hexanes); ¹H NMR (400 MHz, CDCl₃) δ 0.86 (s, 6H), 1.43-1.49 (m, 11H), 2.89 (br s, 1H), 3.13-3.17 (m, 2H), 3.32 (s, 2H), 3.78 (br s, 2H), 5.09-5.13 (m, 2H), 5.71-5.81 (m, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 24.4, 28.6, 34.7, 36.5, 42.9, 50.4, 70.8, 79.8, 116.4, 134.6, 155.8; FT-ICR-MS calcd for $C_{14}H_{27}NNaO_3^+$ [M + Na]⁺ *m/z* 280.1883, found 280.1886.

11

2-(Anthracen-9-yl)ethyl 2,2-dimethyl-4-(allylamino)butyl carbonate (11, TFA salt).

N,N-Diisopropylethylamine (304 μL , 1.74 mmol) was added to a solution of alcohol **23** (251 mg, 0.98 mmol) in dry CH_2Cl_2 (25 mL) at 0 $^\circ\text{C}$. 1,1'-Carbonyldiimidazole (283 mg, 1.74 mmol) was then added to the solution followed by warming to rt. After 24 h, the reaction was washed with water (2 x 10 mL), brine (10 mL) and then dried over Na_2SO_4 . After filtration and concentration *in vacuo*, the crude residue was purified by column chromatography (SiO_2 , EtOAc) to give the imidazole carbamate as a colorless oil (316 mg, 92%); R_f 0.61 (EtOAc); ^1H NMR (400 MHz, CDCl_3) δ 1.01 (s, 6H), 1.42 (s, 9H), 1.56 (t, $J = 7.8$ Hz, 2H), 3.21 (br s, 2H), 3.76 (br s, 2H), 4.12 (s, 2H), 5.07-5.09 (m, 2H), 5.70-5.79 (m, 1H), 7.07 (s, 1H), 7.42 (s, 1H), 8.13 (s, 1H); ^{13}C NMR (100 MHz, CDCl_3) δ 24.2, 28.6, 33.7, 36.7, 42.5, 50.0, 75.9, 79.8, 116.4, 117.2, 130.9, 134.5, 137.2, 148.9, 155.4.

A solution of alcohol **25** (191 mg, 0.86 mmol) in dry THF (1 mL) was added dropwise to a slurry of NaH (103 mg of 60% in mineral oil, 2.57 mmol) in dry THF (5 mL) at -5 $^\circ\text{C}$ and stirred for 30 minutes. A solution of the above imidazole carbamate (316 mg, 0.90 mmol) in dry THF (1 mL) was then added dropwise to the reaction mixture. The reaction was stirred overnight, then the mixture was filtered through Celite and the filter cake was washed with Et_2O . The filtrate was washed with water (2 x 10 mL) and the combined aqueous layers were extracted with Et_2O (3 x 10 mL). The combined organic phase was washed with brine, dried over Na_2SO_4 , filtered and

concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 1:19 EtOAc:CH₂Cl₂) to give Boc-protected **11** (207 mg, 48%) as a yellow oil; *R_f* 0.64 (1:19, EtOAc:CH₂Cl₂); FT-IR 3008, 2974, 1743, 1685, 1256 cm⁻¹; ¹H NMR (400 MHz, CDCl₃) δ 0.98 (s, 6H), 1.46 (s, 9H), 1.53 (t, *J* = 7.8 Hz, 2H), 3.19 (br s, 2H), 3.77-3.82 (m, 2H), 3.90 (s, 2H), 4.05 (t, *J* = 8.0 Hz, 2H), 4.50 (t, *J* = 8.4 Hz, 2H), 5.10-5.13 (m, 2H), 5.74-5.80 (m, 1H), 7.45-7.49 (m, 2H), 7.53-7.57 (m, 2H), 8.01 (d, *J* = 8.4 Hz, 2H), 8.34 (d, *J* = 9.2 Hz, 2H), 8.40 (s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 24.1, 27.6, 28.7, 33.5, 37.1, 42.5, 49.7, 67.3, 76.2, 79.7, 116.2, 124.1, 125.2, 126.4, 127.2, 128.3, 129.5, 130.5, 131.7, 134.5, 155.5, 155.7; FT-ICR-MS calcd for C₂₆H₃₂NO₃⁺ [M + Na]⁺ *m/z* 528.2928, found 528.2720.

Trifluoroacetic acid (0.50 mL, 6.53 mmol) was added to a solution of Boc-protected **11** (12 mg, 0.024 mmol) in dry CH₂Cl₂ (0.50 mL) at 0 °C. After stirring 1h, the volatiles were removed *in vacuo* to afford the TFA salt of **11** (11 mg, 92%) as an oil; ¹H NMR (400 MHz, CDCl₃) δ 0.96 (s, 6H), 1.70 (t, *J* = 8.4 Hz, 2H), 2.99 (br s, 2H), 3.86 (br s, 2H), 4.03 (t, *J* = 8.0 Hz, 2H), 4.49 (t, *J* = 8.0 Hz, 2H), 5.40-5.48 (m, 2H), 5.81-5.91 (m, 1H), 7.45-7.60 (m, 4H), 8.00 (d, *J* = 8.4 Hz, 2H), 8.32 (d, *J* = 8.4 Hz, 2H), 8.39 (s, 1H), 9.06 (br s, 2H); ¹³C NMR (100 MHz, CDCl₃) δ 24.0, 27.4, 33.6, 34.8, 43.3, 50.0, 67.5, 75.3, 124.1, 124.3, 125.2, 126.4, 127.2, 127.5, 128.3, 129.5, 130.5, 131.7, 155.5; FT-ICR-MS calcd for C₂₆H₃₂NO₃⁺ [M + H]⁺ *m/z* 406.2377, found 406.2379.

5.3.8. Experimental Procedures for Determination of Release Rate of **25** and **26**.

The Boc protecting group was removed from each linker as described for **6.2** and immediately placed into a 0.01 *M* solution in MeOH and heated at 55 °C for 24 h. 200

μL aliquots were pulled at $t = 0, 0.25, 0.5, 0.75, 1, 2, 3$ and 24 h and were stored at -20 $^{\circ}\text{C}$ to prevent further release. The solvent was removed under vacuum for 3.5 h at rt and was then returned to -20 $^{\circ}\text{C}$ until analyzed by HPLC. The remaining residue was diluted to 500 μL with HPLC grade CH_2Cl_2 and a 50 μL aliquot was injected into the HPLC fitted with a Waters Nova-Pak HR Silica 6 μm 60 \AA 3.9×300 mm Prep Column using 1% $\text{MeOH}:\text{CH}_2\text{Cl}_2$ with 0.1% triethylamine as the eluent. The percent release was determined by the ratio of the starting linker to the release of **25** or **26**.

To test thermal stability of **11** at 37 $^{\circ}\text{C}$, three samples were incubated at 37 $^{\circ}\text{C}$ for 24 h. The solvent was then evaporated and analyzed as described above.

5.3.9. Experimental Procedure for ^1H NMR Verification of Cyclization

Samples of **6.1** and **7.1** (10 mg) were placed into separate screw-cap NMR tubes. Each sample was diluted with toluene- d_8 (0.5 mL) and a ^1H NMR was taken. This NMR measurement was considered $t = 0$ h. The samples were then heated to 55 $^{\circ}\text{C}$ and held for 3 h (**6.1**) and 5 h (**7.1**), at which time another ^1H NMR spectrum of each sample was obtained. The samples were then heated to ≥ 90 $^{\circ}\text{C}$ and held at that temperature overnight to complete the cyclization. ^1H NMR spectra were once again obtained. To verify the formation of the respective lactam and oxazolidinone, the toluene- d_8 was removed *in vacuo* and the samples were diluted with CDCl_3 and the spectral results were found to be in agreement with published literature.⁶

5.3.10. Synthesis of Ester 27 (Scheme 3.9)

2-((5-(Allyl(*tert*-butoxycarbonyl)amino)pentanoyloxy)-*N*-(2-((1,3-dioxoisindolin-2-yl)oxy)ethyl)-*N,N*-dimethylethanaminium iodide (27). Amino acid **13.2** (98 mg, 0.38 mmol) and the 2-(2-((2-hydroxyethyl)(methyl)amino)ethoxy)-2,3-dihydro-1*H*-isoindole-1,3-dione mono-*O*-phthalimide of *N*-methyl-diethanolamine⁴ were dissolved in dry CH₂Cl₂ (1.7 mL) with stirring. DIC (82 μL, 0.52 mmol) was added to the reaction solution followed by cat. DMAP. After 2 h, the white solids were filtered out and the filter cake was washed with CH₂Cl₂. The filtrate was condensed *in vacuo* and the crude material was purified by column chromatography (SiO₂, 3:1 to 1:0, EtOAc:hexanes gradient) to give the corresponding ester as a light yellow oil (96 mg, 55%). *R_f* 0.55 (EtOAc); ¹H NMR (400 MHz, CDCl₃) δ 1.43 (s, 9H), 1.49-1.62 (m, 4H), 2.33 (t, *J* = 7.4 Hz, 2H), 2.39 (s, 3H), 2.77 (t, *J* = 6.0 Hz, 2H), 2.91 (t, *J* = 5.6 Hz, 2H), 3.16 (br s, 2H), 3.78 (br s, 2H), 4.16 (t, *J* = 5.8 Hz, 2H), 4.30 (t, *J* = 5.4 Hz, 2H), 5.09 (d, *J* = 11.2 Hz, 2H), 5.72-5.78 (m, 1H), 7.72-7.75 (m, 2H), 7.76-7.84 (m, 2H); ¹³C NMR (100 MHz, CDCl₃) δ 22.4, 28.0, 28.6, 34.1, 42.9, 46.3, 55.9, 60.6, 62.3, 76.1, 79.6, 116.5, 123.7, 129.2, 134.6, 155.7, 163.6, 173.6.

To the ester (96 mg, 0.19 mmol) in dry CH₂Cl₂ (1 mL) in a pressure tube was added iodomethane (24 μL, 0.38 mmol). The tube was sealed and heated to 60 °C for 18 h. The solution was then concentrated *in vacuo* to give a crude ammonium salt (yellow gum, 122 mg, 100%) that was used in the next step without further purification. *R_f* 0.20

(1:9, MeOH:CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 1.39 (s, 9H), 1.50-1.56 (m, 4H), 2.40 (t, *J* = 6.6 Hz, 2H), 3.12 (t, *J* = 7.0 Hz, 2H), 3.66 (s, 6H), 3.73 (br s, 2H), 4.26 (br s, 2H), 4.39 (br s, 2H), 4.64 (br s, 2H), 4.77 (br s, 2H), 5.06 (d, *J* = 12.0 Hz, 2H), 5.68-5.74 (m, 1H), 7.76-7.81 (m, 4H); ¹³C NMR (100 MHz, CDCl₃) δ 21.9, 27.5, 28.5, 46.2, 49.9, 53.2, 57.8, 63.2, 64.9, 72.4, 79.5, 116.2, 124.1, 128.6, 134.3, 135.2, 155.6, 163.2, 172.5.

Methyl hydrazine (24 μL, 0.46 mmol) was added to a stirred solution of the crude ammonium salt (49 mg, 0.076 mmol) in 1:1 CH₂Cl₂:EtOH (2 mL) at -40 °C. After 1.5h, the solution was concentrated *in vacuo* and diluted with CH₂Cl₂, causing a white precipitate to form. The solid was filtered and the filter cake was washed with CH₂Cl₂. The filtrate was concentrated *in vacuo* to give **27** (yellow gum, 39 mg, 100%) that was used in the next step without further purification; *R_f* 0.14 (1:9, MeOH:CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 1.41 (s, 9H), 1.51-1.59 (m, 4H), 2.39 (t, *J* = 7.0 Hz, 2H), 3.14 (t, *J* = 6.4 Hz, 2H), 3.48 (s, 6H), 3.74 (br s, 2H), 4.02 (br s, 2H), 4.08 (br s, 2H), 4.19 (br s, 2H), 4.57 (br s, 2H), 5.07 (d, *J* = 15.6 Hz, 2H), 5.70-5.74 (m, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 22.0, 27.6, 28.6, 33.8, 46.2, 49.9, 53.1, 57.8, 63.9, 64.2, 69.2, 79.7, 116.3, 134.3, 155.7, 172.6; FT-ICR-MS calcd for C₁₉H₃₈N₃O₅⁺ [*M*]⁺ *m/z* 388.2806, found 388.2807.

5.3.11. Experimental Procedures for Manufacture of PDMS Microchannel

The device design and detailed fabrication protocol was based on a previous device by Sethu *et al.*⁷ Briefly, the device was fabricated using standard soft lithographic techniques. A silicon wafer was first treated with oxygen plasma in an asher (March Instruments, Concord, MA) and then spin coated with SU-8, a negative photoresist (SU-8

50, MicroChem, Newton, MA). Standard photolithography using a transparency mask (CAD ART Services Inc., Poway, CA) was generated using AutoCAD layout software (Autodesk, Inc., San Rafael, CA), and used to create negative replicas of the channel structures. A silicone elastomer, polydimethylsiloxane (PDMS) (Dow Corning, Midland, MI) was mixed 10:1 with a cross linking agent and poured on top of the silicon wafer, and cured at 60 °C for 12 hours in a petri dish. The cured elastomer with the replicated channel structure was released and access holes to the channels were punched using a 22-gauge syringe needle. The PDMS piece with the channels was bonded irreversibly to a glass slide after treatment with oxygen plasma in the asher. Access tubing (Tygon, Small Parts Inc. Miami Lakes, FL) with a slightly larger diameter than the holes was subsequently press fitted into the punched holes.

5.3.12. Procedure for Loading 27 onto PDMS Microchannel

Ester **27** (39 mg, 0.076 mmol) was placed into a pressure tube with a stir-bar and the headspace was purged with nitrogen. Catalytic PtO₂ was then added, followed by triethoxysilane (14 μL, 0.076 mmol). The headspace was purged with nitrogen and the pressure tube was sealed and heated to 80 °C. After two days, the reaction was cooled to room temperature and the solution was filtered under nitrogen through Celite and the filter cake was washed with dry CH₂Cl₂. The filtrate was concentrated *in vacuo* to give a moisture-sensitive residue, triethoxysilane intermediate **28**, which was immediately loaded onto the PDMS microchannel without further purification by first dissolving in CH₃CN (0.8 M) and then injecting the solution (10 μL, 80 μmol) into the microchannel. After 1h, the microchannel was washed with CH₃CN (5 x 10 μL) and placed in 110 °C

oven for 15 minutes. On cooling, the loaded microchannel was stored at room temperature in a sealed bag until needed.

5.3.13. Experimental Procedures for PDMS Microchannel Reaction and Release

FITC-CHO Attachment

A solution of FITC-CHO (10 μL of 0.02 M, 0.2 μmol) was injected into the aminoxy-functionalized microchannel and allowed to react for 1 h. The remaining FITC-CHO solution was then removed and the microchannel was washed with MeCN (5 x 10 μL). The microchannel was then observed with a fluorescence microscope (excitation/emission, 495 nm/521 nm) and the microchannel was fluorescent.

Boc Deprotection

The linker was activated by removing the Boc protecting group by injecting a 1:4 solution of TFA:MeCN (10 μL) into the microchannel and allowing it to react for 1 h. The microchannel was then evacuated and washed with MeCN (3 x 10 μL). The basification of the ammonium salt was achieved by injecting a 1:1 solution of TEOA:MeCN into the microchannel (2 x 10 μL) and allowing each aliquot to sit for 5 minutes. The microchannel was then washed with MeCN (5 x 10 μL).

Thermally induced cyclization/substrate release

The microchannel with the activated linker was placed on a hot plate at ~ 60 $^{\circ}\text{C}$ for 30 minutes to induce an intramolecular cyclization and release of the FITC-CHO substrate. After cooling the microchannel to rt, it was washed with MeCN (5 x 10 μL) and the washings were collected. The microchannel was then observed with a fluorescence microscope (excitation/emission, 495 nm/521 nm) and it was no longer fluorescent. To

ensure that release of the FITC-CHO moiety occurred upon heating, a fluorescent measurement was taken of the collected washings and fluorescence was observed.

5.4. EXPERIMENTAL PROCEDURES OF CHAPTER 4

5.4.1. Synthesis of Non-Nucleophilic Ester Linker

10

Anthracen-9-ylmethyl dec-9-enoate (10). 9-Decenoic acid (343 mg, 2.02 mmol) and 9-anthracenemethanol (361 mg, 1.73 mmol) were dissolved in dry CH₂Cl₂ (15 mL) with stirring. DIC (395 μ L, 2.52 mmol) was added to the reaction solution followed by cat. DMAP. After 2 h, the white solids were filtered out and the filter cake was washed with CH₂Cl₂. The filtrate was condensed *in vacuo* and the crude material was purified by column chromatography (SiO₂, 0:100 to 1:9 EtOAc:CH₂Cl₂ gradient) to give **10** (506 mg, 81%) as a yellow oil. *R*_f 0.67 (CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 1.24-1.33 (m, 8H), 1.62 (quin, *J* = 5.6 Hz, 2H), 2.00 (q, *J* = 5.6 Hz, 2H), 2.33 (t, *J* = 5.8 Hz, 2H), 4.96 (dd, *J* = 8.0 and 13.6 Hz, 2H), 5.76-5.82 (m, 1H), 6.16 (s, 2H), 7.48-7.51 (m, 2H), 7.56-7.59 (m, 2H), 8.03 (d, *J* = 6.8 Hz, 2H), 8.34 (d, *J* = 7.2 Hz, 2H), 8.50 (s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 25.2, 29.0, 29.1, 29.2, 33.9, 34.5, 58.8, 114.3, 124.1, 125.3, 126.6, 126.8, 129.3, 131.2, 131.6, 139.3, 174.3.

5.4.2. Synthesis of 11

tert-Butyl allylcarbamate. Allyl amine (997 mg, 17.5 mmol) was dissolved in dry CH_2Cl_2 (35 mL) and cooled to 0 °C with stirring. Boc_2O was added to the reaction solution and stirred for 18 h, allowing the reaction to slowly warm to room temperature. Upon completion, the solution was washed with HCl (2 x 13 mL of 1 M solution), dried over Na_2SO_4 , filtered and concentrated *in vacuo* to give *tert*-butyl allylcarbamate (2.55 g, 93%) as white crystals which were used in the next step without further purification. R_f 0.65 (1:1, EtOAc:hexanes); ^1H NMR (400 MHz, CDCl_3) δ 1.44 (s, 9H), 3.73 (br s, 2H), 4.60 (br s, 1H), 5.08-5.19 (m, 2H), 5.78-5.88 (m, 1H); ^{13}C NMR (100 MHz, CDCl_3) δ 28.6, 43.3, 79.6, 115.9, 135.1, 156.0.

11

tert-Butyl allyl(methyl)carbamate (11). A suspension of NaH (579 mg, 24.1 mmol) in dry THF (100 mL) was cooled to 0 °C with stirring. A solution of *tert*-butyl allylcarbamate (2.53 g, 16.1 mmol) in dry THF (10 mL) was added to the reaction flask dropwise and stirred for 20 min at 0 °C. Methyl iodide (1.5 mL, 24.1 mmol) was added and the reaction was stirred for 16 h allowing it to slowly come to room temperature. The reaction was quenched with sat. NH_4Cl (150 mL) and the aqueous phase was extracted with Et_2O (3 x 90 mL) and wash with brine (100 mL). The combined organics

were dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 1:3, EtOAc:hexanes) to give **11** (1.03 g, 38%) as a light yellow oil. *R_f* 0.53 (1:3, EtOAc:hexanes); ¹H NMR (400 MHz, CDCl₃) δ 1.45 (s, 9H), 2.81 (s, 3H), 3.80 (br s, 2H), 5.08-5.13 (m, 2H), 5.70-5.80 (m, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 28.6, 33.9, 51.5, 79.6, 116.5, 133.9, 155.9.

***tert*-Butyl methyl(3-(triethoxysilyl)propyl)carbamate.** **11** (518 mg, 3.02 mmol) and cat. PtO₂ were placed into a pressure vial with a stir bar and the vial was purged with nitrogen. Triethoxysilane (600 μL, 3.25 mmol) was then added and the vial was purged with nitrogen and then sealed. The reaction vial was heated to 85-95 °C and stirred for one week. Upon completion, the reaction mixture was filtered through Celite and the filter cake was washed with dry CH₂Cl₂. The solution was then concentrated *in vacuo* to give crude *tert*-butyl methyl(3-(triethoxysilyl)propyl)carbamate as a brown oil that was used in the next step without further purification. ¹H NMR (400 MHz, CDCl₃) δ 0.55 (t, *J* = 8.4 Hz, 2H), 1.20-1.25 (m, 9H), 1.44 (s, 9H), 1.58-1.61 (m, 2H), 2.82 (s, 3H), 3.16 (br s, 2H), 3.78-3.87 (quin, *J* = 6.8 Hz, 6H); ¹³C NMR (100 MHz, CDCl₃) δ 7.6, 18.5, 21.5, 28.7, 34.4, 58.6, 59.3, 79.2, 156.0.

5.4.3. Anhydrous NP Loading Procedure (with heat)

12

The functionalization of the iron oxide NPs was done following a modified procedure as described by Galeotti *et al.*⁸ Briefly, Fe₃O₄ NPs (150 mg) were placed in a round bottom flask and purged with nitrogen. CHCl₃ (20 mL) was then added via syringe and the NPs were suspended with sonication (3 x 10 min with 5 min pause between sonication). While maintaining sonication, a solution of the alkoxy silane linker (819 mg, 2.44 mmol) in CHCl₃ (5 mL) was added dropwise via a syringe. Sonication was continued for 10 min after completion of the addition of the silylated linker and was then mechanically stirred for 2.5 h at room temperature. Then, the reaction flask was heated to 60-65 °C and stirred for 48 h. After cooling, the coated NPs were magnetically separated and the supernatant was removed followed by washing with CHCl₃ (5 x 10 mL). The coated NPs were then dried with an oil vacuum pump for 30 min. The vial was then purged with nitrogen and heated to 100-110 °C for 24 h to yield **12** (197 mg, 10.8 molecules/nm²).

5.4.4. Acidic Boc-Deprotection of Functionalized NPs to Afford 2° Amine

13

A suspension of **12** (13.2 mg) in CH₂Cl₂ was sonicated for 15 seconds to break any aggregation and was then cooled to 0 °C. Trifluoroacetic acid was then added and the vial was allowed to stand for 1 h. Upon completion, the NPs were magnetically

separated, washed with CH_2Cl_2 (5 x 5 mL) and dried with an oil vacuum pump for 2 h to afford **13** (5.5 molecules/ nm^2).

Excess fluorescein isothiocyanate was added to **13** (12 mg) suspended in dry THF (2 mL) and sonicated for 30 seconds. The suspension was allowed to stand for 4.5 h before the NPs were magnetically separated and the supernatant was removed. The NPs were washed with sat. NaHCO_3 (3 x 5 mL), MeOH (5 x 5 mL), and EtO_2 (2 x 5 mL). The washed NPs were dried with an oil vacuum pump to yield the fluorescent NPs.

5.4.5. Synthesis of Non-Nucleophilic Olefinic Ester

17.1

2-(Anthracen-9-yl)ethyl pent-4-enoate (17.1). 4-Pentenoic acid (159 μL , 1.56 mmol) and 2-(anthracen-9-yl)ethanol (281 mg, 1.26 mmol) were dissolved in dry CH_2Cl_2 (15 mL) with stirring. DIC (305 μL , 1.95 mmol) was added to the reaction solution followed by cat. DMAP. After 2 h, the white solids were filtered out and the filter cake was

washed with CH₂Cl₂. The filtrate was condensed *in vacuo* and the crude material was purified by column chromatography (SiO₂, 1:1 hexanes:CH₂Cl₂) to give **17.1** (359 mg, 93%) as a yellow oil. *R_f* 0.36 (1:1 hexanes:CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 2.35-2.46 (m, 4H), 3.99 (t, *J* = 8.0 Hz, 2H), 4.50 (t, *J* = 7.8 Hz, 2H), 5.00-5.08 (m, 2H), 5.79-5.88 (m, 1H), 7.46-7.50 (m, 2H), 7.54-7.58 (m, 2H), 8.02 (d, *J* = 8.4 Hz, 2H), 8.38 (d, *J* = 8.8 Hz, 2H), 8.40 (s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 27.5, 29.0, 33.8, 64.3, 115.7, 124.3, 125.1, 126.2, 127.0, 129.2, 129.4, 130.5, 131.7, 136.8, 173.4.

5.4.6. Synthesis of Non-Nucleophilic Olefinic Carbonate

Allyl 1*H*-imidazole-1-carboxylate. *N,N*-diisopropylethylamine (5.37 mL, 30.8 mmol) was added to a solution of allyl alcohol (1.21 g, 20.8 mmol) in dry CH₂Cl₂ (69 mL). The solution was cooled to 0 °C and 1,1'-carbonyldiimidazole (5.07 g, 31.2 mmol) was added and the reaction was stirred overnight. The reaction was washed with water (2 x 40 mL), brine (40 mL) and dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, EtOAc) to give allyl 1*H*-imidazole-1-carboxylate (2.24 g, 71%) as a light yellow oil. *R_f* 0.51 (EtOAc); ¹H NMR (400 MHz, CDCl₃) δ 4.87 (d, *J* = 5.6 Hz, 2H), 5.37 (d, *J* = 10.0 Hz, 1H), 5.44 (d, *J* = 16.8 Hz, 1H), 5.95-6.03 (m, 1H), 7.05 (s, 1H), 7.42 (s, 1H), 8.13 (s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 68.8, 117.3, 120.6, 130.6, 130.9, 137.3, 148.6.

17.2

Allyl (2-(anthracen-9-yl)ethyl) carbonate (17.2). 1,8-Diazabicyclo[5.4.0]undec-7-ene (1.68 mL, 11.2 mmol) was added to a solution of allyl 1*H*-imidazole-1-carboxylate (1.71 g, 11.2 mmol) in dry CH₃CN (56 mL). The reaction solution was stirred for 10 minutes before adding 2-(anthracen-9-yl)ethanol (2.50 g, 11.2 mmol). The reaction was stirred overnight before quenching with sat. NH₄Cl (40 mL). The aqueous phase was extracted with EtOAc (2 x 40 mL) and the combined organic phases were washed with brine, dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 3:1, CH₂Cl₂:hexanes) to give **17.2** (2.33 g, 68%) as yellow crystals. *R_f* 0.63 (3:1, CH₂Cl₂:hexanes); ¹H NMR (400 MHz, CDCl₃) δ 4.06 (t, *J* = 8.0 Hz, 2H), 4.52 (t, *J* = 8.4 Hz, 2H), 4.69 (d, *J* = 5.6 Hz, 2H), 5.31 (dd, *J* = 10.8, 1.8 Hz, 1H), 5.40 (dd, *J* = 17.6, 1.2 Hz, 1H), 5.93-6.03 (m, 1H), 7.47-7.50 (m, 2H), 7.55-7.59 (m, 2H), 8.02 (d, *J* = 8.4 Hz, 2H), 8.35 (d, *J* = 8.8 Hz, 2H), 8.40 (s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 27.6, 67.4, 68.7, 119.1, 124.1, 125.2, 126.4, 127.2, 128.3, 129.5, 130.5, 131.7, 131.8, 155.3.

5.4.7. Synthesis of Non-Nucleophilic Olefinic Carbamate

2-(Anthracen-9-yl)ethyl 1H-imidazole-1-carboxylate. *N,N*-Diisopropylethylamine (408 μL , 2.34 mmol) was added to a solution of 2-(anthracen-9-yl)ethanol (346 mg, 1.55 mmol) in dry CH_2Cl_2 (8 mL), the solution was cooled to 0 $^\circ\text{C}$ and 1,1'-carbonyldiimidazole (380 mg, 2.34 mmol) was added. After stirring overnight, the reaction solution was washed with water (2 x 5 mL), brine, dried over Na_2SO_4 , filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO_2 , CH_2Cl_2 to 3:2, EtOAc: CH_2Cl_2 gradient) to give 2-(anthracen-9-yl)ethyl 1H-imidazole-1-carboxylate (436 mg, 89%) as a pale yellow solid. R_f 0.23 (1:19, EtOAc: CH_2Cl_2); ^1H NMR (400 MHz, CDCl_3) δ 4.16 (t, $J = 7.4$ Hz, 2H), 4.80 (t, $J = 7.6$ Hz, 2H), 7.02 (s, 1H), 7.31 (s, 1H), 7.50 (t, $J = 7.6$ Hz, 2H), 7.58 (t, $J = 7.4$ Hz, 2H), 8.00 (s, 1H), 8.04 (d, $J = 8.0$ Hz, 2H), 8.33 (d, $J = 8.8$ Hz, 2H), 8.44 (s, 1H); ^{13}C NMR (100 MHz, CDCl_3) δ 27.0, 68.0, 117.3, 123.8, 125.3, 126.6, 127.5, 127.9, 129.7, 130.5, 130.8, 131.7, 137.3, 149.0.

17.3

2-(Anthracen-9-yl)ethyl allylcarbamate (17.3). 1,8-Diazabicyclo[5.4.0]undec-7-ene (206 μL , 1.38 mmol) was added to a solution of 2-(anthracen-9-yl)ethyl 1*H*-imidazole-1-carboxylate (436 mg, 1.38 mmol) in dry CH_3CN (7 mL). The reaction solution was stirred for 10 minutes before adding allylamine (114 μL , 1.51 mmol). The reaction was stirred overnight before quenching with sat. NH_4Cl (40 mL). The aqueous phase was extracted with EtOAc (2 x 5 mL) and the combined organic phases were washed with brine, dried over Na_2SO_4 , filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO_2 , CH_2Cl_2 to 2:3, EtOAc: CH_2Cl_2 gradient) to give **17.3** (356 mg, 85%) as pale yellow crystals. R_f 0.72 (1:19, EtOAc: CH_2Cl_2); ^1H NMR (400 MHz, CDCl_3) δ 3.85 (br s, 2H), 4.00 (t, $J = 7.8$ Hz, 2H), 4.47 (t, $J = 7.6$ Hz, 2H), 4.74 (br s, 1H), 5.13-5.22 (m, 2H), 5.84-5.90 (m, 1H), 7.45-7.49 (m, 2H), 7.53-7.56 (m, 2H), 8.01 (d, $J = 8.4$ Hz, 2H), 8.36 (d, $J = 8.8$ Hz, 2H), 8.39 (s, 1H); ^{13}C NMR (100 MHz, CDCl_3) δ 28.1, 43.7, 64.9, 116.3, 124.4, 125.1, 126.2, 126.9, 129.4, 130.6, 131.7, 134.7, 156.7.

5.4.8. Procedure for the Addition of Polysaccharides to Functionalized NPs

Fe_3O_4 NPs functionalized with linker **17.2** (11 mg) were suspended in DMSO (1 mL). Then, excess polysaccharide (D-lactose or 6 kDa dextran) was added to the suspension and the mixture was stirred overnight. The coated NPs were magnetically separated and

the supernatant was decanted. The resulting NPs were washed once with DMSO and twice with MeOH before being dried using high vacuum to afford polysaccharide coated NPs (12 mg).

5.4.9. Synthesis of Monodispersed SiO₂@Fe₃O₄ NPs

The Fe₃O₄ NPs were coated with a thin silica shell using the modified procedure of Pinho *et al.*⁹ Briefly, the EMG 304 ferrofluid (1 mL, 233 mg NPs, 8.55 x 10¹⁶ NPs) was added to Millipore water (98 mL) and was then added to a solution of EtOH (312 mL) and NH₄OH (6.2 mL, 28-30%) with rapid mechanical stirring. Tetraethyl orthosilicate (TEOS) (2.13 mL) was then added to the colloidal suspension and was stirred for 12 h. An aliquot was removed to allow for characterization. The NPs were magnetically separated and the remaining colloidal supernatant was centrifuged at 13,200 RPM for 20 min. The NPs were then washed 5x with EtOH with magnetic separation and centrifugation after each wash. The excess EtOH was then removed by rotary evaporation and the NPs were dried under vacuum for 3 h. The resulting SiO₂@Fe₃O₄ NPs were characterized by IR, TGA, DLS, ζ-potential, SQUID and TEM.

5.4.10. Synthesis of Carbamate Linker for AMF-Induced Hydrolytic Release

2-((*tert*-Butyldimethylsilyloxy)ethan-1-ol). A solution of TBSCl (2.34 g, 15.5 mmol) in dry CH₂Cl₂ (20 mL) was added dropwise over 1 h to a solution of ethylene glycol (8 mL, 143 mmol) and Et₃N (2.80 mL, 19.9 mmol) in dry CH₂Cl₂ (25 mL) at 0 °C and was stirred overnight. The solvent was removed *in vacuo* and the remaining oil was extracted

with hexanes (4x) and the combined extractions were washed twice with sat. NH_4Cl , once with brine and was dried over Na_2SO_4 , filtered and concentrated *in vacuo* to afford the mono-TBS protected diol 2-((*tert*-butyldimethylsilyl)oxy)ethan-1-ol (2.52 g, 92%) as a colorless oil and was used without further purification. R_f 0.59 (1:3, EtOAc:hexanes).

2-((*tert*-Butyldimethylsilyl)oxy)ethyl 1*H*-imidazole-1-carboxylate. 1,1'-

Carbonyldiimidazole (3.47 g, 21.4 mmol) was added to a solution of the mono-TBS protected diol (2.52 g, 14.3 mmol) and *N,N*-diisopropylethylamine (3.70 mL, 21.4 mmol) in dry CH_2Cl_2 (48 mL) at 0 °C and was stirred for 6 h. The reaction was washed twice with water and the combined aqueous phases were extracted once with CH_2Cl_2 . The combined organic layers were then washed twice with sat. NH_4Cl , once with brine and were dried over Na_2SO_4 , filtered and concentrated *in vacuo* to afford crude 2-((*tert*-butyldimethylsilyl)oxy)ethyl 1*H*-imidazole-1-carboxylate as a colorless oil and was used without further purification. R_f 0.36 (1:3, EtOAc:hexanes); ^1H NMR (400 MHz, CDCl_3) δ 0.06 (s, 6H), 0.88, (s, 9H), 3.93 (t, $J = 4.8$ Hz, 2H), 4.71 (t, $J = 4.8$ Hz, 2H), 7.06 (s, 1H), 7.42 (s, 1H), 8.13 (s, 1H); ^{13}C NMR (100 MHz, CDCl_3) δ -5.2, 18.4, 25.9, 61.0, 69.4, 117.3, 130.9, 137.3, 149.0.

Methyl *N*-(hex-5-en-1-yl)carbamate. Triethylamine (12.8 mL, 91.0 mmol) was slowly added to a solution of hex-5-en-1-amine hydrochloride (4.11 g, 30.334 mmol) in dry CH₂Cl₂ (300 mL) at 0 °C, then methyl chloroformate (3.52 mL, 45.5 mmol) was added dropwise and the reaction was stirred overnight. The remaining white solids were removed by filtration and the filter cake was washed with CH₂Cl₂. The filtrate was then washed with 1 M HCl (2 x 100 mL) and the combined aqueous phases were extracted once with CH₂Cl₂. The combined organic phases were washed with brine, dried over Na₂SO₄, filtered and concentrated *in vacuo* to afford the crude methyl *N*-(hex-5-en-1-yl)carbamate as a yellow oil which was used without further purification. *R_f* 0.42 (1:3, EtOAc:hexanes); ¹H NMR (400 MHz, CDCl₃) δ 1.40 (quin, *J* = 7.2 Hz, 2H), 1.50 (quin, *J* = 7.2 Hz, 2H), 2.05 (q, *J* = 7.2 Hz, 2H), 3.15-3.16 (m, 2H), 3.64 (s, 3H), 4.68 (br s, 1H), 4.92-5.01 (m, 2H), 5.72-5.82 (m, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 26.2, 29.7, 33.5, 41.2, 52.1, 114.9, 138.6, 157.3.

***N*-methyl-1-aminohex-5-ene.** Lithium aluminum hydride (2.30 g, 60.7 mmol) was slowly added to a solution of crude *N*-(hex-5-en-1-yl)carbamate (30.334 mmol) in dry Et₂O (75 mL) at 0 °C, then the cooling bath was removed and the reaction was heated at reflux overnight. The reaction was then cooled to 0 °C and carefully quenched with aq. Rochelle's Salt (50%, 40 mL) and stirred for 0.5 h. The layers were separated and the aqueous phase was extracted twice with Et₂O. The combined organic phases were

washed with brine, dried over Na₂SO₄, filtered and the solvent was removed by distillation followed by distillation of the product to afford *N*-methyl-1-aminohex-5-ene (3.26 g ,95%) as a colorless oil. *R_f* 0.38 (1:9, MeOH:CH₂Cl₂ with 1% NH₄OH); ¹H NMR (400 MHz, CDCl₃) δ 1.39-1.55 (m, 4H), 2.05 (q, *J* = 6.8 Hz, 2H), 2.41 (s, 3H), 2.56 (t, *J* = 6.6 Hz, 2H), 4.91-5.01 (m, 2H), 5.72-5.84 (m, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 26.9, 29.6, 33.8, 36.7, 52.2, 114.6, 139.0.

2-((*tert*-Butyldimethylsilyl)oxy)ethyl *N*-(hex-5-en-1-yl)-*N*-methylcarbamate. The carbamate was synthesized as described by Heller, *et.al.*¹⁰ DBU (2.13 mL, 14.3 mmol) was added to a solution of crude 2-((*tert*-butyldimethylsilyl)oxy)ethyl 1*H*-imidazole-1-carboxylate (14.3 mmol) in dry MeCN (70 mL) and was stirred for 10 min, then *N*-methyl-1-aminohex-5-ene (1.60 g, 14.3 mmol) was added and the reaction was stirred overnight. The reaction was then washed twice with sat. NH₄Cl and the combined aqueous layers were extracted three times with EtOAc. The combined organic phases were washed with brine, dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 1:3, EtOAc:hexanes) to give a colorless oil 2-((*tert*-Butyldimethylsilyl)oxy)ethyl *N*-(hex-5-en-1-yl)-*N*-methylcarbamate (3.56 g, 79%). *R_f* 0.40 (1:3, EtOAc:hexanes); ¹H NMR (400 MHz, CDCl₃) δ 0.06 (s, 6H), 0.89 (s, 9H), 1.38 (quin, *J* = 7.4 Hz, 2H), 1.52, (quin, *J* = 7.6 Hz, 2H), 2.07 (q, *J* = 7.2 Hz, 2H), 2.88 (s, 3H), 3.25 (t, *J* = 7.2 Hz, 2H), 3.80 (t, *J* = 5.0 Hz, 2H), 4.13 (t, *J* = 5.0 Hz, 2H), 4.93-5.02 (m, 2H), 5.73-5.84 (m, 1H); ¹³C NMR (100 MHz,

CDCl₃) δ -5.1, 18.5, 26.1, 27.6, 33.6, 34.1, 49.0, 62.0, 66.8, 114.9, 138.7, 156.7; FT-ICR-MS calcd for C₁₆H₃₄NO₃Si⁺ [M+H]⁺ m/z 316.2302, found 316.2307.

2-Hydroxyethyl *N*-(hex-5-en-1-yl)-*N*-methylcarbamate. TBAF (1 *M* in THF, 10.6 mL, 10.6 mmol) was added dropwise to a solution of 2-((*tert*-Butyldimethylsilyl)oxy)ethyl *N*-(hex-5-en-1-yl)-*N*-methylcarbamate (2.58 g, 8.17 mmol) in dry THF (16 mL) at 0 °C and was stirred overnight. The reaction solution was washed twice with sat. NaHCO₃ and the combined aqueous layers were extracted three times with Et₂O. The combined organic phases were washed with brine, dried over Na₂SO₄, filtered and concentrated *in vacuo* to afford crude 2-hydroxyethyl *N*-(hex-5-en-1-yl)-*N*-methylcarbamate as a yellow oil and was used without further purification. *R_f* 0.12 (1:3, EtOAc:hexanes); ¹H NMR (400 MHz, CDCl₃) δ 1.40 (quin, *J* = 7.8 Hz, 2H), 1.55 (quin, *J* = 7.6 Hz, 2H), 2.08 (q, *J* = 6.8 Hz, 2H), 2.90 (s, 3H), 3.26 (t, *J* = 7.2 Hz, 2H), 3.78-3.82 (q, *J* = 4.4 Hz, 2H), 4.23 (t, *J* = 4.4 Hz, 2H), 4.94-5.02 (m, 2H), 5.74-5.84 (m, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 25.9, 27.4, 33.6, 34.7, 48.9, 62.6, 67.7, 115.0, 138.6, 157.4.

2-(Methanesulfonyloxy)ethyl *N*-(hex-5-en-yl)-*N*-methylcarbamate. Methanesulfonyl chloride (728 mL, 9.40 mmol) was added dropwise to a solution of the crude 2-hydroxyethyl *N*-(hex-5-en-1-yl)-*N*-methylcarbamate (8.17 mmol) and triethylamine (1.72

mL, 12.3 mmol) in CH₂Cl₂ (27 mL) at 0 °C and stirred overnight. The reaction was then washed twice with sat. NH₄Cl and the combined aqueous layers were extracted twice with CH₂Cl₂. The combined organic phases were washed with brine, dried over Na₂SO₄, filtered and concentrated *in vacuo* to give crude 2-(methanesulfonyloxy)ethyl *N*-(hex-5-en-yl)-*N*-methylcarbamate as a light yellow oil (2.15 g). *R_f* 0.36 (major product) & 0.68 (1:1, EtOAc:hexanes); ¹H NMR (400 MHz, CDCl₃, *R_f* 0.36) δ 1.37 (quin, *J* = 7.6 Hz, 2H), 1.54 (quin, *J* = 7.6 Hz, 2H), 2.07 (q, *J* = 7.2 Hz, 2H), 2.89 (s, 3H), 3.01 (s, 3H), 3.26 (t, *J* = 7.2 Hz, 2H), 4.32-4.34 (m, 2H), 4.39-4.41 (m, 2H), 4.93-5.02 (m, 2H), 5.74-5.81 (m, 1H); ¹³C NMR (100 MHz, CDCl₃, *R_f* 0.36) δ 26.1, 27.0, 33.5, 34.1, 37.9, 49.2, 62.8, 68.1, 114.9, 138.6, 155.9.

2-((1,3-Dioxo-2,3-dihydro-1*H*-isoindol-2-yl)oxy)ethyl *N*-(hex-5-en-1-yl)-*N*-methylcarbamate. K₂CO₃ (1.17 g, 8.47 mmol) was added to a solution of the combined 2-(methanesulfonyloxy)ethyl *N*-(hex-5-en-yl)-*N*-methylcarbamate products (*R_f* 0.36 & 0.68) (2.15 g, 7.70 mmol) in DMSO (26 mL), followed by the addition of *N*-hydroxyphthalimide (2.39 g, 14.6 mmol) and the dark red solution was heated at 75 °C overnight. The yellow solution was cooled to rt and slowly quenched with water and extracted four times with EtOAc. The combined organic phase was washed three times with water, once with brine, dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 1:1, EtOAc:hexanes) to give 2-((1,3-Dioxo-2,3-dihydro-1*H*-isoindol-2-yl)oxy)ethyl *N*-(hex-5-en-1-yl)-*N*-

methylcarbamate (2.02 g, 71% over 3 steps) as a yellow oil. R_f 0.55 (1:1, EtOAc:hexanes); ^1H NMR (400 MHz, CDCl_3) δ 1.35 (quin, $J = 7.6$ Hz, 2H), 1.52 (quin, $J = 7.6$ Hz, 2H), 2.05 (q, $J = 7.2$ Hz, 2H), 2.85 (br s, 3H), 3.24 (t, $J = 7.2$ Hz, 2H), 4.41 (s, 4H), 4.91-5.00 (m, 2H), 5.72-5.82 (m, 1H), 7.72-7.75 (m, 2H), 7.80-7.82 (m, 2H); ^{13}C NMR (100 MHz, CDCl_3) δ 26.1, 27.2, 33.5, 34.6, 49.1, 62.8, 76.7, 114.8, 123.7, 129.2, 134.7, 138.7, 156.1, 163.5; FT-ICR-MS calcd for $\text{C}_{18}\text{H}_{23}\text{N}_2\text{O}_5^+$ $[\text{M}+\text{H}]^+$ m/z 347.1601, found 347.1606.

23

2-(Aminoxy)ethyl N-(hex-5-en-1-yl)-N-methylcarbamate (23). Hydrazine monohydrate (34 mL, 0.70 mmol) was added to a solution of 2-((1,3-Dioxo-2,3-dihydro-1H-isoindol-2-yl)oxy)ethyl N-(hex-5-en-1-yl)-N-methylcarbamate (258 mg, 0.74 mmol) in CH_2Cl_2 (4 mL) at 0 °C and was stirred for 1 h. The solids were then filtered off and the filter cake was washed with ample CH_2Cl_2 . The filtrate was then concentrated *in vacuo* to afford **23** (154 mg, 96%) as a colorless oil without further purification. R_f 0.24 (1:1, EtOAc:hexanes); ^1H NMR (400 MHz, CDCl_3) δ 1.36 (quin, $J = 7.6$ Hz, 2H), 1.52 (quin, $J = 7.6$ Hz, 2H), 2.05 (q, $J = 7.2$ Hz, 2H), 2.86 (s, 3H), 3.24 (t, $J = 7.2$ Hz, 2H), 3.80 (t, $J = 3.6$ Hz, 2H), 4.26 (t, $J = 4.4$ Hz, 2H), 4.91-5.00 (m, 2H), 5.42 (br s, 2H), 5.71-5.82 (m, 1H); ^{13}C NMR (100 MHz, CDCl_3) δ 26.0, 27.3, 33.5, 34.6, 48.8, 62.9, 74.3, 114.8, 138.7, 156.7; FT-ICR-MS calcd for $\text{C}_{10}\text{H}_{21}\text{N}_2\text{O}_3^+$ $[\text{M}+\text{H}]^+$ m/z 217.1547, found 217.1548.

26

2-(((E/Z)-2-(Anthracen-9-yl)ethylidene)amino)oxyethyl N-(hex-5-en-1-yl)-N-methylcarbamate (26). 2-(Anthracen-9-yl)acetaldehyde¹¹ (175 mg, 0.79 mmol) was added to a solution of **23** (156 mg, 0.72 mmol) in CH₂Cl₂ (4 mL) and stirred for 1 h. The reaction solution was concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 0:1 to 3:17, EtOAc:CH₂Cl₂ gradient) to give **26** (291 mg, 96%) as a yellow oil. *R_f* 0.55 (1:19, EtOAc:CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 0.78 (br s, 0.25H), 0.87 (br s, 0.25H), 1.26 (br s, 1.44H), 1.35-1.41 (m, 2H), 1.55-1.63 (m, 2H), 1.92-2.07 (m, 2H), 2.78 (br s, 0.68H), 2.95 (s, 1.91H), 3.14 (br s, 0.46H), 3.22 (br s, 0.46H), 3.30-3.34 (m, 1.33H), 4.26 (dd, *J* = 16.8, 5.4 Hz, 1.78H), 4.49-4.52 (m, 3.48H), 4.68 (d, *J* = 4.4 Hz, 1.31H), 4.88-5.02 (m, 2H), 5.69-5.79 (m, 1H), 6.74 (t, *J* = 5.0 Hz, 0.60H), 7.47-7.57 (m, 4.48H), 8.01-8.05 (m, 2H), 8.19 (d, *J* = 8.4 Hz, 1H), 8.30 (d, *J* = 8.8 Hz, 1H), 8.43 (s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 25.3, 26.6, 28.7, 33.6, 34.8, 48.8, 64.1, 72.9, 114.9, 124.2, 125.3, 126.3, 127.1, 128.7, 129.4, 130.3, 131.7, 138.7, 150.3, 156.6; FT-ICR-MS calcd for C₂₆H₃₁N₂O₃⁺ [M+H]⁺ *m/z* 419.2329, found 419.2333.

Y = ONH₂ or ON=CHCH₂Ar

2-(Aminooxy)ethyl N-methyl-N-(6-(triethoxysilyl)hexyl)carbamate or 2-(((E/Z)-2-(anthracen-9-yl)ethylidene)amino)oxyethyl N-methyl-N-(6-(triethoxysilyl)hexyl)carbamate. Following a procedure outlined by Sabourault *et al.*,¹² catalytic PtO₂ and

triethoxysilane (131 mL, 0.71 mmol) was added to **23** or **26** (153 mg, 0.71 mmol) in a pressure tube. The tube was flushed with N₂, sealed and heated to 90 °C for 48 h. The reaction solution was cooled to rt and filtered through Celite into a flask flushed with N₂ and the filter cake was washed with ample dry CH₂Cl₂. The filtrate was concentrated *in vacuo* to afford the crude material as a light brown oil which was used without further characterization or purification due to its sensitivity to moisture.

5.4.11. SQUID Measurements

The magnetic properties of the magnetic NPs were measured using a Quantum Design MPMS-5S superconducting quantum interference device (SQUID) magnetometer (in the temperature range from 2 to 400 K) courtesy of Professor Lance DeLong (University of Kentucky). The samples were loaded in a gel capsule and secured inside a standard drinking straw with small holes punched in both the straw and capsule for equalization of pressure and temperature. M(H) data was taken by starting the sample at saturation, 5 T, and then cycling to -5 T and back to 5 T in different step ranges to see the details of the hysteresis. The data was taken using DC magnetization to disturb the magnetic NPs as little as possible during the measurement.

5.4.12. Synthesis of AO@SiO₂@Fe₃O₄ and FL@SiO₂@Fe₃O₄ NPs

The suspension of SiO₂@Fe₃O₄ NPs was placed under mild vacuum and heated to 60 °C for 8 h. This process was used to remove the catalytic ammonia thus increasing the chances of obtaining a thin organic monolayer on the surface of the NPs. The removal of the ammonia decreased the pH of the solution from 11.7 to 8.8. Then, EtOH (5 mL) was

added to 2-(aminoxy)ethyl *N*-methyl-*N*-(6-(triethoxysilyl)hexyl)carbamate or 2-(((*E/Z*)-(2-(anthracen-9-yl)ethylidene)amino)oxy)ethyl *N*-methyl-*N*-(6-(triethoxysilyl)hexyl)carbamate (1.454 mmol) and the solution was added to the NP suspension with rapid mechanical stirring. The mixture was stirred for 20 h. The majority of the AO@SiO₂@Fe₃O₄ or FL@SiO₂@Fe₃O₄ NPs were then magnetically separated and the remaining colloidal supernatant was centrifuged at 13,200 RPM for 20 min. The NPs were then washed 5x with EtOH with magnetic separation and centrifugation after each wash. The excess EtOH was then removed by rotary evaporation and the NPs were dried under vacuum for 3 h. The resulting NPs were characterized by IR, TGA, DLS, ζ-potential and TEM.

5.4.13. AMF-Induced Heating of Bulk Solution

Temperature measurements were taken with a Neoptix Nomad fitted with a fiber optic temperature sensor. All data was recorded using Neoptix NeoLink software. AMF conditions were set to 501.6 amps and a frequency of 204 kHz. Each AMF pulse lasted for 2 or 5 min followed by 2 or 5 min of without an AMF for a combined total of 40 min of AMF exposure. All samples were started at room temperature and were allowed to cool at room temperature; all heating was induced using only an AMF. The control was 0.75 mL of 2:1 PBS:acetonitrile without SiO₂@Fe₃O₄ NPs, which gave a ΔT of 4.8 ± 0.1 °C with a 5 min AMF pulse. The ΔT of a 5 min AMF pulse with 7.0 mg of SiO₂@Fe₃O₄ NPs in 0.75 mL 2:1 PBS:acetonitrile was +16.4 ± 0.3 °C. The ΔT from the start of the first AMF pulse to the start of the sixth AMF pulse was +4 °C.

5.4.14. Assay of Percent 27 Released from NPs

To determine the percent of **27** released from FL@SiO₂@Fe₃O₄ NPs, it is necessary to determine the residual amount of 2-(((E/Z)-(2-(anthracen-9-yl)ethylidene)amino)oxy)ethyl *N*-methyl-*N*-(6-(triethoxysilyl)hexyl)carbamate remaining on the FL@SiO₂@Fe₃O₄ NPs post AMF exposure. After recording the fluorescence intensity of the last (eighth) AMF pulse, the NPs were magnetically separated and the AMF supernatant was removed. The isolated NPs then were washed 5x with MeCN followed by magnetic separation to remove any hydrogen bound **27**. To the washed NPs was added 1 mL of 5% HF in EtOH. The suspension was stirred until all NPs had dissolved resulting in a light yellow solution. The acidic solution was added to a separatory funnel and then basified using sat. aq. NaHCO₃. The basic solution was extracted 3 x with Et₂O and the combined extracts were concentrated by rotary evaporation and dried under vacuum. The resulting residue was dissolved in a 2:1 mixture of PBS:MeCN (0.75 mL) at pH 7.4 and the fluorescence was measured. This measured fluorescence intensity was then added to the total fluorescence intensity measured in the supernatant after the final AMF pulse, and the combined intensity was set to 100%. The results from all three experiments were normalized by dividing the fluorescent intensity by the milligrams of FL@SiO₂@Fe₃O₄ NPs used for the experiment.

5.4.15. Synthesis of Thiol Linker for Loading onto Au@Fe₃O₄ NPs

4-((*tert*-Butyldimethylsilyl)oxy)butan-1-ol. A solution of TBSCl (5.20 g, 34.5 mmol) in dry CH₂Cl₂ (60 mL) was added dropwise over 1 h to a solution of 1,4-butanediol (14.7 mL, 166 mmol) and Et₃N (6.99 mL, 49.8 mmol) in dry CH₂Cl₂ (50 mL) at 0 °C and was stirred overnight. The solvent was removed *in vacuo* and the remaining oil was extracted with hexanes (4x) and the combined extractions were washed twice with sat. NH₄Cl, once with brine and was dried over Na₂SO₄, filtered and concentrated *in vacuo* to afford crude 4-((*tert*-butyldimethylsilyl)oxy)butan-1-ol (6.58 g, 93%) as a colorless oil and was used without further purification. *R_f* 0.44 (1:3, EtOAc:hexanes).

4-((*tert*-Butyldimethylsilyl)oxy)butyl methanesulfonate. Methanesulfonyl chloride (2.87 mL, 37.0 mmol) was added to a solution of crude 4-((*tert*-butyldimethylsilyl)oxy)butan-1-ol (6.58 g, 32.2 mmol) and Et₃N (6.79 mL, 48.3 mmol) in dry CH₂Cl₂ (107 mL) at 0 °C and was stirred for 2 h. The reaction solution was washed twice with sat. NH₄Cl and the combined aqueous layers were extracted twice with CH₂Cl₂. The combined organic phases were washed once with brine and was dried over Na₂SO₄, filtered and concentrated *in vacuo* to afford 4-((*tert*-butyldimethylsilyl)oxy)butyl methanesulfonate (9.03 g, 99%) as an orange oil and was used without further purification. *R_f* 0.52 (1:3, EtOAc:hexanes); ¹H NMR (400 MHz, CDCl₃) δ 0.04 (s, 6H), 0.88 (s, 9H), 1.62 (quin, *J* = 6.0 Hz, 2H), 1.83 (quin, *J* = 7.2 Hz, 2H), 2.99 (s, 3H), 3.64

(t, $J = 6.0$ Hz, 2H), 4.26 (t, $J = 6.6$ Hz, 2H); ^{13}C NMR (100 MHz, CDCl_3) δ -5.2, 18.5, 26.1, 28.8, 37.6, 62.4, 70.3.

2-(4-((*tert*-Butyldimethylsilyl)oxy)butyl)-2,3-dihydro-1*H*-isoindole-1,3-dione.

Phthalimide (8.55 g, 58.1 mmol) was added to a solution of 4-((*tert*-butyldimethylsilyl)oxy)butyl methanesulfonate (8.64 g, 30.6 mmol) and K_2CO_3 (5.07 g, 36.7 mmol) in DMSO (180 mL) and the solution was heated to 75 °C for 17 h. The reaction was then cooled to rt and was quenched with water. The aqueous solution was extracted with EtOAc (4x) and the combined organic phases were washed with water (3x). The organic phase was then washed with brine, dried over Na_2SO_4 , filtered and concentrated *in vacuo* to afford 2-(4-((*tert*-butyldimethylsilyl)oxy)butyl)-2,3-dihydro-1*H*-isoindole-1,3-dione (9.27 g, 91%) as white crystals and was used without further purification. R_f 0.59 (1:3, EtOAc:hexanes); ^1H NMR (400 MHz, CDCl_3) δ 0.03 (s, 6H), 0.87 (s, 9H), 1.55 (quin, $J = 6.4$ Hz, 2H), 1.74 (quin, $J = 7.4$ Hz, 2H), 3.63 (t, $J = 6.4$ Hz, 2H), 3.70 (t, $J = 7.2$ Hz, 2H), 7.65 (dd, $J = 2.4, 2.8$ Hz, 2H), 7.83 (dd, $J = 1.6, 3.4$ Hz, 2H); ^{13}C NMR (100 MHz, CDCl_3) δ -5.1, 18.5, 25.3, 26.1, 30.2, 38.1, 62.7, 123.4, 132.4, 134.0, 168.6.

(4-Aminobutoxy)(*tert*-butyl)dimethylsilane. Hydrazine monohydrate (6.74 mL, 139 mmol) was added to a solution of crude 2-(4-((*tert*-butyldimethylsilyl)oxy)butyl)-2,3-dihydro-1*H*-isoindole-1,3-dione (9.27 g, 27.8 mmol) in CH₂Cl₂ (140 mL) at 0 °C and was stirred overnight, allowing the reaction to come to rt. The white precipitate was filtered and the filter cake was washed with ample CH₂Cl₂. The crude solution was concentrated *in vacuo* to afford (4-aminobutoxy)(*tert*-butyl)dimethylsilane (3.99 g, 71%) as a light yellow oil and was used without further purification. *R_f* 0.26 (1:9, MeOH:CH₂Cl₂ with 1% NH₄OH); ¹H NMR (400 MHz, CDCl₃) δ 0.03 (s, 6H), 0.87 (s, 9H), 1.44-1.55 (m, 4H), 1.61 (br s, 2H), 2.68 (t, *J* = 6.8 Hz, 2H), 3.60 (t, *J* = 6.2 Hz); ¹³C NMR (100 MHz, CDCl₃) δ -5.1, 18.5, 26.1, 30.4, 30.5, 42.3, 63.3.

(((3-Bromopropyl)sulfanyl)diphenylmethyl)benzene. K₂CO₃ (2.28 g, 16.5 mmol) followed by 1,3-dibromopropane (7.61 mL, 75 mmol) was added to a solution of triphenylmethanethiol (4.22 g, 15.3 mmol) in dry THF (75 mL) under N₂. The reaction was refluxed for 24 h before cooling to rt. The reaction solution was washed twice with water, extracted twice with Et₂O, washed with brine, dried over Na₂SO₄, filtered and concentrated *in vacuo*. The excess 1,3-dibromopropane was distilled off to afford (((3-bromopropyl)sulfanyl)diphenylmethyl)benzene (5.94 g, 98%) as white crystals. *R_f* 0.54 (1:3, CH₂Cl₂:hexanes); ¹H NMR (400 MHz, CDCl₃) δ 1.81 (quin, *J* = 6.8 Hz, 2H), 2.32

(t, $J = 6.8$ Hz, 2H), 3.32 (t, $J = 6.8$ Hz, 2H), 7.19-7.30 (m, 9H), 7.40-7.44 (m, 6H); ^{13}C NMR (100 MHz, CDCl_3) δ 30.5, 31.8, 32.5, 66.9, 126.9, 128.1, 129.8, 144.9.

12,12,13,13-Tetramethyl-1,1,1-triphenyl-11-oxa-2-thia-6-aza-12-silatetradecane.

(((3-bromopropyl)sulfanyl)diphenylmethyl)benzene (800 mg, 2.01 mmol) was added to a solution of (4-aminobutoxy)(*tert*-butyl)dimethylsilane (1.02 g, 5.03 mmol) in MeCN (20 mL) and the reaction was heated to 55 °C for 24 h. After cooling to rt, the reaction was quenched with sat. NaHCO_3 and extracted three times with EtOAc. The combined organic phases were washed with brine, dried over Na_2SO_4 , filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO_2 , 0:1 to 1:4, MeOH: CH_2Cl_2 with 1% NH_4OH gradient) to give 12,12,13,13-tetramethyl-1,1,1-triphenyl-11-oxa-2-thia-6-aza-12-silatetradecane (852 mg, 82%) as an orange oil. R_f 0.33 (1:4, MeOH: CH_2Cl_2 with 1% NH_4OH); ^1H NMR (400 MHz, CDCl_3) δ 0.04 (s, 6H), 0.88 (s, 9H), 1.51-1.52 (m, 4H), 1.60 (quin, $J = 7.4$ Hz, 2H), 2.17 (t, $J = 7.0$ Hz, 2H), 2.57 (t, $J = 7.2$ Hz, 4H), 3.59 (t, $J = 6.0$ Hz, 2H), 7.17-7.28 (m, 9H), 7.39-7.41 (m, 6H); ^{13}C NMR (100 MHz, CDCl_3) δ -5.1, 18.6, 25.9, 26.2, 28.5, 29.9, 30.7, 48.6, 49.5, 63.2, 66.8, 126.8, 128.1, 129.8, 145.1.

***tert*-Butyl N-(4(((*tert*-butyl)dimethylsilyloxy)butyl)-N-(3-((triphenylmethyl)sufanyl)propyl)carbamate.** Boc_2O (348 mg, 1.60 mmol) was added to a solution of 12,12,13,13-

tetramethyl-1,1,1-triphenyl-11-oxa-2-thia-6-aza-12-silatetradecane (754 mg, 1.45 mmol) and Et₃N (224 μ L, 1.60 mmol) in CH₂Cl₂ (5 mL) at 0 °C. After 3 h, the reaction solution was washed twice with sat. NH₄Cl and the aqueous phase was extracted twice with CH₂Cl₂. The combined organic phases were washed with brine, dried over Na₂SO₄, filtered and concentrated *in vacuo* to afford crude *tert*-butyl *N*-(4((*tert*-butyldimethylsilyloxy)butyl)-*N*-(3-((triphenylmethyl)sufanyl)propyl)carbamate as an orange oil and was used without further purification. *R_f* 0.81 (1:19, EtOAc:CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 0.03 (s, 6H), 0.88 (s, 9H), 1.39 (br s, 4H), 1.45 (br s, 2H), 1.52 (s, 9H), 2.13 (t, *J* = 7.4 Hz, 2H), 3.05 (br s, 4H), 3.58 (t, *J* = 6.0 Hz, 2H), 7.18-7.29 (m, 9H), 7.39-7.41 (m, 6H); ¹³C NMR (100 MHz, CDCl₃) δ -5.1, 18.5, 25.9, 26.2, 27.6, 28.6, 29.6, 30.3, 46.5, 47.1, 63.1, 66.8, 79.3, 126.8, 128.1, 129.8, 145.1, 155.6.

***tert*-Butyl *N*-(4-hydroxybutyl)-*N*-(3-((triphenylmethyl)sufanyl)propyl)carbamate.**

TBAF (1.89 mL of 1 *M* solution in THF, 1.89 mmol) was added to a solution of crude *tert*-butyl *N*-(4((*tert*-butyldimethylsilyloxy)butyl)-*N*-(3-((triphenylmethyl)sufanyl)propyl)carbamate (1.45 mmol) in dry THF (3 mL) at 0 °C and the reaction was stirred overnight, allowing the reaction to warm to rt. Upon completion, the reaction was washed twice with sat. NaHCO₃ and the combined aqueous phases were extracted three times with Et₂O. The combined organic layers were washed with brine, dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 3:7, EtOAc:CH₂Cl₂) to give *tert*-butyl *N*-(4-hydroxybutyl)-*N*-(3-

((triphenylmethyl)sulfanyl)propyl)carbamate (453 mg, 62% over 2 steps) as a light yellow oil. R_f 0.52 (3:7, EtOAc:CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 1.40 (s, 9H), 1.47-1.51 (m, 4H), 1.58 (quin, J = 7.6 Hz, 2H), 3.08 (br s, 4H), 3.63 (t, J = 6.0 Hz, 2H), 7.19-7.30 (m, 9H), 7.41-7.43 (m, 6H); ¹³C NMR (100 MHz, CDCl₃) δ 24.8, 28.2, 28.6, 29.5, 29.7, 46.6, 46.9, 62.6, 66.8, 79.5, 126.8, 128.0, 129.7, 145.0, 155.7.

4-(((tert-Butoxy)carbonyl)((3-((triphenylmethyl)sulfanyl)propyl))amino) butyl 1H-imidazole-1-carboxylate. 1,1'-Carbonyldiimidazole (214 mg, 1.32 mmol) was added to a solution of *tert*-butyl *N*-(4-hydroxybutyl)-*N*-(3-((triphenylmethyl)sulfanyl)propyl)carbamate (444 mg, 0.88 mmol) and (*i*-Pr)₂NEt (228 μL, 1.32 mmol) in dry CH₂Cl₂ (3 mL) at 0 °C and was stirred overnight. The reaction solution was washed twice with water and extracted once with CH₂Cl₂. The combined organic layers were washed twice with sat. NH₄Cl, once with brine, were dried over Na₂SO₄, filtered and concentrated *in vacuo* to afford crude 4-(((tert-butoxy)carbonyl)((3-((triphenylmethyl)sulfanyl)propyl))amino) butyl 1H-imidazole-1-carboxylate (517 mg, 98%) as a light yellow oil and was used without further purification. R_f 0.50 (3:7, EtOAc:CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 1.42 (s, 9H), 1.59 (br s, 4H), 1.76 (quin, J = 6.8 Hz, 2H), 2.18 (t, J = 7.4 Hz, 2H), 3.11 (br s, 4H), 4.42 (t, J = 6.6 Hz, 2H), 7.08 (s, 1H), 7.20-7.31 (m, 9H), 7.42-7.44 (m, 7H), 8.15 (s, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 24.6, 25.9, 28.2, 28.5, 29.4, 46.5 (2 C's), 66.8, 68.1, 79.6, 117.2, 126.7, 128.0, 129.7, 130.8, 137.2, 144.9, 148.8, 155.5.

2-(2-(((4-(((*tert*-Butoxy)carbonyl)((3-(((triphenylmethyl)sulfanyl)propyl))amino)

butoxy)carbonyl)oxy)ethoxy)-2,3-dihydro-1*H*-isoindole-1,3-dione. DBU (129 μ L, 0.86 mmol) was added to a solution of crude *tert*-butyl *N*-(4-hydroxybutyl)-*N*-(3-(((triphenylmethyl)sulfanyl)propyl)carbamate (517 mg, 0.86 mmol) in dry MeCN (4 mL). After stirring for 10 min, 2-(2-hydroxyethoxy)-2,3-dihydro-1*H*-isoindole-1,3-dione (178 mg, 0.86 mmol) was added and the reaction was stirred overnight. Upon completion, the reaction was washed twice with sat. NH₄Cl and the combined aqueous layers were extracted three times with EtOAc. The combined organic layers were washed with brine, dried over Na₂SO₄, filtered and concentrated *in vacuo*. The crude material was purified by column chromatography (SiO₂, 3:17, EtOAc:CH₂Cl₂) to give 2-(2-(((4-(((*tert*-butoxy)carbonyl)((3-(((triphenylmethyl)sulfanyl) propyl))amino)butoxy)carbonyl)oxy)ethoxy)-2,3-dihydro-1*H*-isoindole-1,3-dione (350 mg, 55% over 2 steps) as a colorless oil. *R_f* 0.75 (3:17, EtOAc:CH₂Cl₂); ¹H NMR (400 MHz, CDCl₃) δ 1.40 (s, 9H), 1.46-1.64 (m, 6H), 2.15 (t, *J* = 7.4 Hz, 2H), 3.06 (br s, 4H), 4.14 (t, *J* = 6.4 Hz, 2H), 4.43-4.48 (m, 4H), 7.18-7.29 (m, 9H), 7.39-7.42 (m, 6H), 7.73-7.76 (m, 2H), 7.81-7.85 (m, 2H); ¹³C NMR (100 MHz, CDCl₃) δ 24.6, 26.1, 28.2, 28.6, 29.5, 46.5, 46.6, 65.2, 68.1, 75.6, 79.5, 123.8, 126.8, 128.0, 129.0, 129.7, 134.7, 145.0, 155.1, 155.5, 163.5.

***N*-(4-(((2-(aminooxy)ethoxy)carbonyl)oxy)butyl)-*N*-((*tert*-butoxy)carbonyl)-3-((triphenylmethyl)sulfanyl)propan-1-amine.** Hydrazine monohydrate (51 μL , 1.04 mmol) was added to a solution of 2-(2-(((4-(((*tert*-butoxy)carbonyl)((3-((triphenylmethyl)sulfanyl)propyl))amino)butoxy)carbonyl)oxy)ethoxy)-2,3-dihydro-1*H*-isoindole-1,3-dione (154 mg, 0.21 mmol) in CH_2Cl_2 at 0 $^\circ\text{C}$ and stirred for 2 h. When complete, the white precipitate was removed by filtration and the filter cake was washed with ample CH_2Cl_2 . The filtrate was concentrated *in vacuo* to afford **28** (127 mg, 100%) as a colorless oil and did not require further purification. R_f 0.52 (1:3, EtOAc: CH_2Cl_2); ^1H NMR (400 MHz, CDCl_3) δ 1.38 (s, 9H), 1.48-1.62 (m, 6H), 2.14 (t, $J = 7.4$ Hz, 2H), 3.05 (br s, 4H), 3.85 (t, $J = 4.6$ Hz, 2H), 4.12 (t, $J = 6.4$ Hz, 2H), 4.33 (t, $J = 4.4$ Hz, 2H), 5.51 (br s, 2H), 7.18-7.21 (m, 3H), 7.25-7.29 (m, 6H), 7.39-7.41 (m, 6H); ^{13}C NMR (100 MHz, CDCl_3) δ 24.7, 26.2, 27.5, 28.6, 29.5, 46.7 (2 C's), 65.5, 66.8, 68.0, 73.4, 79.5, 126.8, 128.0, 129.7, 145.0, 155.5, 155.6.

AMAH: ¹H NMR (400 MHz) DMSO-d₆

AMAH: ¹³C NMR (100 MHz) DMSO-d₆

ADMH: ^{13}C NMR (176 MHz) DMSO- d_6

AAAn: ¹H NMR (400 MHz) CDCl₃

AAO: ¹³C NMR (100 MHz) CDCl₃

5: $^1\text{H NMR}$ (400 MHz) CDCl_3

5: ^{13}C NMR (100 MHz) CDCl_3

14.1: ¹H NMR (400 MHz) CDCl₃

14.1: ^{13}C NMR (100 MHz) CDCl_3

14.2: ¹H NMR (400 MHz) CDCl₃

14.2: ^{13}C NMR (100 MHz) CDCl_3

14.3: $^1\text{H NMR}$ (400 MHz) CDCl_3

14.3: ^{13}C NMR (100 MHz) CDCl_3

14.4: $^1\text{H NMR}$ (400 MHz) CDCl_3

14.4: ^{13}C NMR (100 MHz) CDCl_3

Boc-protected 7.1: ^1H NMR (400 MHz) CDCl_3

Boc-protected 7.1: ^{13}C NMR (100 MHz) CDCl_3

Boc-protected 7.2: $^1\text{H NMR}$ (400 MHz) CDCl_3

Boc-protected 7.2: ^{13}C NMR (100 MHz) CDCl_3

Boc-protected 8: $^1\text{H NMR}$ (400 MHz) CDCl_3

Boc-protected 8: ^{13}C NMR (100 MHz) CDCl_3

17.1: ¹H NMR (400 MHz) CDCl₃

17.1: ^{13}C NMR (100 MHz) CDCl_3

17.2: $^1\text{H NMR}$ (400 MHz) CDCl_3

17.2: ¹³C NMR (100 MHz) CDCl₃

17.3: $^1\text{H NMR}$ (400 MHz) CDCl_3

17.3: ^{13}C NMR (100 MHz) CDCl_3

23: $^1\text{H NMR}$ (400 MHz) CDCl_3

23: ^{13}C NMR (100 MHz) CDCl_3

23 After Oximation With 2-(9-anthryl)acetaldehyde: ^1H NMR (400 MHz) CDCl_3

23 After Oximation With 2-(9-anthryl)acetaldhyde: ^{13}C NMR (100 MHz) CDCl_3

FL@SiO₂@Fe₃O₄: FT-IR with ATR

B.1. List of Publications

The work presented in this dissertation was published in various peer-reviewed journals and/or patented. The following list summarizes the publications and patents that arose from my research, and the chapters in which the work is described.

Publications:

1. Biswas, S.; Knipp, R. J.; Gordon, L. E.; Nandula, S. R.; Gorr, S. U.; Clark, G. J.; Nantz M. H. Hydrophobic Oxime Ethers: A Versatile Class of pDNA and siRNA Transfection Lipids. *ChemMedChem* **2011**, *6*, 2063-2069. [Chapter 1]
2. Fu, X.-A.; Li, M.; Knipp, R. J.; Nantz, M. H.; Bousamra, M. Noninvasive Detection of Lung Cancer Using Exhaled Breath. *Cancer Medicine* **2014**, *3*, 174-181. [Chapter 2]
3. Bousamra, M.; Schumer, E.; Li, M.; Knipp, R. J.; Nantz, M. H.; van Berkel, V. H.; Fu, X.-A. Quantitative Analysis of Exhaled Carbonyl Compounds Distinguishes Benign From Malignant Pulmonary Disease. *Journal of Thoracic and Cardiovascular Surgery* **2014**, *148*, 1074-1081. [Chapter 2]
4. Knipp, R. J.; Li, M.; Fu, X.-A.; Nantz, M. H. A Versatile Probe for Chemoselective Capture and Analysis of Carbonyl Compounds in Exhaled Breath. Submitted to *Analytical Chemistry* [Chapter 2]
5. Li, M.; Knipp, R. J.; Nantz, M. H.; Bousamra, M.; Fu, X.-A. Analysis of Exhaled Breath for Identification of Lung Cancer Biomarkers. Submitted to *Clinica Chimica Acta*. [Chapter 2]

Hydrophobic Oxime Ethers: A Versatile Class of pDNA and siRNA Transfection Lipids

Souvik Biswas,^[a] Ralph J. Knipp,^[a] Laura E. Gordon,^[b] Seshagiri R. Nandula,^[c] Sven-Ulrik Gorr,^[c] Geoffrey J. Clark,^[b] and Michael H. Nantz^{*,[a]}

The manipulation of the cationic lipid structures to increase polynucleotide binding and delivery properties, while also minimizing associated cytotoxicity, has been a principal strategy for developing next-generation transfection agents. The polar (DNA binding) and hydrophobic domains of transfection lipids have been extensively studied; however, the linking domain comprising the substructure used to tether the polar and hydrophobic domains has attracted considerably less attention as an optimization variable. Here, we examine the use of an oxime ether as the linking domain. Hydrophobic oxime ethers were readily assembled via click chemistry by oximation of hy-

drophobic aldehydes using an aminoxy salt. A facile ligation reaction delivered the desired compounds with hydrophobic domain asymmetry. Using the MCF-7 breast cancer, H1792 lung cancer and PAR C10 salivary epithelial cell lines, our findings show that lipoplexes derived from oxime ether lipids transfect in the presence of serum at higher levels than commonly used liposome formulations, based on both luciferase and green fluorescent protein (GFP) assays. Given the biological compatibility of oxime ethers and their ease of formation, this functional group should find significant application as a linking domain in future designs of transfection vectors.

Introduction

Cationic lipids and their derived liposomes have become the most well-studied and widely used synthetic, nonviral gene delivery vehicles since Felgner et al.^[1] first disclosed DOTMA-mediated gene transfer in 1987.^[2,3] Due to the major limitations of viral vectors, such as associated immune responses, limited polynucleotide carrying capacity and high cost,^[4,5] cationic lipids remain an attractive alternative. The advantages of low immunogenicity, the ability to transfect RNA or DNA of nearly unlimited size,^[6,7] and the relative ease of cationic lipid-plasmid DNA (pDNA) or RNA complex (lipoplex) formulation^[8] continue to attract interest aimed at developing safer and more efficient cationic lipids for use as transfection agents.^[9]

Cationic lipid molecules, such as the prototypical dual chain lipids DOTMA^[2] and DOTAP^[3] (Figure 1), contain a polar, positively charged (DNA binding) head group connected to a hydrophobic domain via a linking functionality. These three principal structural components of cationic glycerol-type lipids

have been extensively studied in efforts to improve lipid-mediated intracellular delivery of polynucleotides to mammalian cells.^[10] Many structure-activity relationships have been determined,^[11–13] particularly for the hydrophobic domain. Indeed, the hydrophobic domain's structural variables of chain length, degree of unsaturation, and domain asymmetry are among the strongest contributors to transfection efficacy.^[14] Fewer direct structural comparisons of changes in the cationic lipid backbone, or linking domain, have been reported, with the most well-known comparison being that of the diether DOTMA versus the diester DOTAP.^[15] The linking functionality, and to a lesser extent the cationic head group, seem to be the principal determinants of toxicity.^[16–18] The linker determines conformational flexibility, degree of stability, and biodegradability. Among the most studied chemical functionalities comprising the linking domain of transfection lipids are the ether, ester, ortho ester,^[19,20] carbamate,^[21] amide,^[21,22] and phosphono^[23] moieties.

Abstract

Early detection of lung cancer is a key factor for increasing the survival rates of lung cancer patients. The analysis of exhaled breath is promising as a non-invasive diagnostic tool for diagnosis of lung cancer. We demonstrate the quantitative analysis of carbonyl volatile organic compounds (VOCs) and identification of lung cancer VOC markers in exhaled breath using unique silicon microreactor technology. The microreactor consists of thousands of micropillars coated with an ammonium aminoxy salt for capture of carbonyl VOCs in exhaled breath by means of oximation reactions. Captured aminoxy-VOC adducts are analyzed by nano-electrospray Fourier transform-ion cyclotron resonance (FT-ICR) mass spectrometry (MS). The concentrations of 2-butanone, 2-hydroxyacetaldehyde, 3-hydroxy-2-butanone, and 4-hydroxyhexenal (4-HHE) in the exhaled breath of lung cancer patients ($n = 97$) were significantly higher than in the exhaled breath of healthy smoker and nonsmoker controls ($n = 88$) and patients with benign pulmonary nodules ($n = 32$). The concentration of 2-butanone in exhaled breath of patients ($n = 51$) with stages II through IV non-small cell lung cancer (NSCLC) was significantly higher than in exhaled breath of patients with stage I ($n = 34$). The carbonyl VOC profile in exhaled breath determined using this new silicon microreactor technology provides for the noninvasive detection of lung cancer.

Introduction

The US National Lung Screening Trial recently found that periodic computed tomography (CT) screening of heavy smokers could reduce mortalities of lung cancer patients by as much as 20% [1, 2]. Currently, CT and bronchoscopy are the principal techniques used for lung cancer detection [3, 4]. In recent years, the analysis of exhaled breath has become an international research frontier because of its applicability for noninvasive diagnosis of diseases [5–17]. Several approaches have been developed to analyze exhaled breath including the use of sensor arrays [7–9, 15–17], proton-transfer reaction mass spectrometry (PTR-MS) [18–20], selected ion flow tube mass spectrometry (SIFT-MS) [21, 22], and gas

chromatography-mass spectrometry (GC-MS) [13, 18, 23–26]. Real-time analysis of volatile organic compounds (VOCs) in exhaled breath by PTR-MS has been established to monitor variation in VOCs with time [27–31]. Although some VOCs in exhaled breath have been reported as lung cancer markers, there has been no clinical adoption of breath analysis methods for diagnosis because of the large number of VOCs in exhaled breath and the lack of cancer-specific VOC markers for reliably predicting lung cancer [5–17].

Here, we describe the quantitative analysis of carbonyl VOCs in exhaled breath and the identification of specific carbonyl VOCs related to lung cancer stages and histology using silicon microreactors for the capture of carbonyl VOCs. Our approach only requires a patient to fill a 1-L

Quantitative analysis of exhaled carbonyl compounds distinguishes benign from malignant pulmonary disease

Michael Bousamra II, MD,^a Erin Schumer, MS, MD,^a Mingxiao Li, PhD,^b Ralph J. Knipp, MS,^c Michael H. Nantz, PhD,^c Victor van Berkel, MD, PhD,^a and Xiao-An Fu, PhD^b

Objectives: The analysis of exhaled breath is a promising noninvasive tool for the diagnosis of lung cancer, but its clinical relevance has yet to be established. We report the analysis of exhaled volatile carbonyl compounds for the identification of specific carbonyl cancer markers to differentiate benign pulmonary disease from early-stage lung cancer and to compare its diagnostic accuracy with positron emission tomography (PET) scans.

Methods: Aminoxy-coated silicon microchips were used for the selective capture of exhaled carbonyls by an oximation reaction. Breath samples were collected and directed through the silicon chips by applying a vacuum. Carbonyl adducts were analyzed by Fourier transform mass spectrometry. Eighty-eight control subjects, 107 patients with lung cancer (64 stage 0, I, or II), 40 patients with benign pulmonary disease, and 7 patients with a solitary pulmonary metastasis participated. Analysis of cancer markers was performed blinded to the pathologic results.

Results: Four carbonyls were defined as cancer markers with significantly higher concentrations in patients with lung cancer. The number of increased cancer markers distinguished benign disease from both early and stage III and IV lung cancer. For early-stage disease, defining greater than 2 increased markers as diagnostic of lung cancer resulted in 83% sensitivity and 74% specificity. PET scans for this same cohort resulted in 90% sensitivity but only 39% specificity. Markers normalized for 3 of the 4 markers after resection of the lung cancer.

Conclusions: Analysis of specific exhaled carbonyls can differentiate early lung cancer from benign pulmonary disease. Breath analysis was more specific than PET for a lung cancer diagnosis. Judicious use of these data may expedite the care of patients with lung cancer. (*J Thorac Cardiovasc Surg* 2014;148:1074-81)

With the advent and increasing acceptance of computed tomography (CT) screening for lung cancer, the importance of distinguishing benign from malignant intrathoracic disease is increasing. The reported 20% reduction in lung cancer mortality from the National Lung Cancer Screening Trial is partially offset by the morbidity, cost and occasional mortality incurred by pursuing nonmalignant pulmonary nodules and adenopathy.¹

Given a resectable pulmonary nodule, and depending on its degree of suspicion, there are multiple options for diagnostic workup.² Serial CT scanning to observe growth, resolution, or stability is commonly used for subcentimeter lesions. Positron emission tomography (PET) scintigraphy

of the lesion may be used to assess the probability of malignancy in nodules larger than 8 mm. Bronchoscopy and percutaneous biopsy are options for tissue acquisition but the associated costs and risks are significant. In addition, diagnostic yields are highly conditional with respect to tumor size, location, and operator skill. Proceeding directly to surgical resection is appropriate when the probability of malignancy is high and the surgical risk is low. Conversely, surgical resection of nonmalignant disease is a clinical failure because, in most such instances, the natural course of the benign process would never have harmed the patient. Furthermore, PET scans are frequently falsely positive both in cases of solitary pulmonary nodules and in cases with hilar and mediastinal adenopathy. All may lead to increased clinical suspicion of lung cancer and an obligation to rule out malignancy by surgical intervention. Thus, it is important to develop reliable methods that minimize the diagnostic burden to patients who have no significant disease while expediting treatment in patients who have lung cancer.²⁻⁴

Breath analysis of patients with suspected lung cancer is a developing modality with the potential to fulfill this goal.⁵ Linus Pauling first studied the volatile constituents of breath in individuals maintained on an elemental diet in 1971.⁶ In recent years, the analysis of exhaled breath has become a broad research frontier.^{5,7,8} Several approaches have been developed, including sensor arrays,⁹⁻¹³ proton transfer

A Versatile Probe for Chemoselective Capture and Analysis of Carbonyl Compounds in Exhaled Breath

Ralph J. Knipp,[†] Mingxiao Li,[‡] Xiao-An Fu^{*,‡} and Michael H. Nantz^{*,†}

[†]Department of Chemistry, [‡]Department of Chemical Engineering, University of Louisville, Louisville, Kentucky 40292, United States

ABSTRACT: We describe an aminoxy reagent for the capture of trace aldehyde and ketone volatile organic compounds (VOCs) in exhaled breath. The reagent, 4-(2-aminoxyethyl)-morpholin-4-ium chloride (AMAH), when coated onto micropillars within a silicon microreactor, chemoselectively and covalently retains carbonyl VOCs from exhaled breath. The AMAH-carbonyl adducts are then rinsed from the microreactor with methanol and directly analyzed by Fourier transform-ion cyclotron resonance (FT-ICR) mass spectrometry (MS), where the aminium ion of the reagent enhances the sensitivity for high mass accuracy. We also outline a protocol for treatment of the AMAH-carbonyl adducts with poly(4-vinylpyridine) to afford the corresponding volatile carbonyl adducts that now can be analyzed by gas chromatography-mass spectrometry (GC-MS). This convenient protocol imparts flexibility for the identification and quantification of isomeric VOCs using both FT-ICR-MS and GC-MS. Representative breath analyses are given to illustrate this applicability of AMAH.

Quantitative Analysis of Carbonyl Compounds in Exhaled Breath

ABSTRACT

Quantitative analysis of trace volatile carbonyl compounds in human breath is reported. The approach is based on microreactor chips fabricated from silicon wafers. The microreactors have thousands of micropillars in microfluidic channels for uniformly distributing a gaseous breath sample flowing through the channels. The surfaces of the micropillars are functionalized with a quaternary ammonium aminoxy salt, [2-(aminoxy)ethyl]-*N,N,N*-trimethylammonium iodide (ATM), for chemoselective trapping of trace carbonyl compounds by means of oximation reactions. ATM adducts and unreacted ATM are eluted from the microreactor with 50 μ L of methanol and directly analyzed by nanospray Fourier transform ion cyclotron resonance (FTICR) mass spectrometry (MS). The capture efficiencies of formaldehyde, acetaldehyde, acetone and 2-butanone have been determined to be above 95%. The levels of these and other carbonyl compounds in exhaled breath samples from 45 non-smokers and 45 current smokers were compared. Formaldehyde, acetaldehyde and acetone were present in significantly higher concentrations in the current smokers group, while 2-butanone and 3-hydroxy-2-butanone were not affected by smoking cigarettes.

INTRODUCTION

Analysis of volatile organic compounds (VOCs) at trace levels has attracted much interest because of demanding applications in non-invasive disease diagnosis and monitoring environment air quality. Human exhaled breath primarily consists of atmospheric gases, water vapor, and trace level metabolic VOCs.^{1,2} Breath analysis could potentially provide a non-invasive and painless means to detect disease, and the sampling of breath does not require skilled medical staff.³⁻⁷ Breath analysis challenges existing analytical methods because VOC concentrations in breath are beyond instrument limits of detection.^{3,7} This problem is further exacerbated by other interfering gases that are mixed in large concentration with the VOCs. Gas chromatography coupled with a mass spectrometer detector (GC-MS) is currently the dominant technique for analysis of trace VOCs. A complex preconcentration process consisting of cryogenic adsorption and thermal desorption is typically required before trace VOC samples can enter into a GC column.⁸⁻¹⁴ Solid-phase microextraction (SPME) is a popular preconcentration method and a rapid extraction technique for analysis of VOCs from a variety of matrixes by GC-MS.¹⁵⁻¹⁸ However, SPME is only semiquantitative due to the inefficiency inherent with physical adsorption on the SPME fiber. Other methods including selected ion flow tube mass spectrometry (SIFT-MS),¹⁹⁻²⁰ proton transfer reaction mass spectrometry (PTR-MS)²¹⁻²³ and electronic nose methods²⁴⁻²⁵ also have been used for analysis of breath.

Thermally induced substrate release via intramolecular cyclizations of Amino esters and Amino carbonates

ABSTRACT

The relative cleavage of an alcohol from a panel of amino esters and amino carbonates via intramolecular cyclization was examined as a mechanism for substrate release. Thermal stability at 37 °C was observed only for the seven-membered ring progenitors. Applicability of the approach was illustrated by δ -lactam formation within a poly(dimethylsiloxane) microchannel for release of a captured fluorescent probe.

1. Introduction

We disclose here a brief study on the propensity of amino ester and amino carbonate substrates of the type indicated in Fig. 1 to undergo intramolecular cyclization for purposes of releasing substrate HO-R'. Similar intramolecular cyclization modes of substrate release previously have been exploited as mechanisms for drug delivery.^{1–4} In these cases, the released substrate is either a phenol (R' = Ar) or an aniline derivative so that the intramolecular cyclization occurs rapidly at physiological temperature,⁵ generally with a half-life from minutes to 1 h.⁶ Intramolecular cyclizations of this type also have been used to unmask aromatic hydroxyl,⁷ amine⁸ or thiol⁹ moieties as mechanisms to initiate electron cascade reactions or for release of polymer-bound drugs.¹⁰ Again the focus was to use the intramolecular cyclization for rapid drug release at physiological temperature, and this required R' to be aromatic. Few examples have used this approach to release non-aromatic alcohols,^{11,12} the most common being for the delivery of 5-halo deoxyuridine analogs.^{13–15}

Our interest in control over heat-induced intramolecular cyclization as a mechanism for substrate release led us to investigate linkers that would expel HO-R' at temperatures above 37 °C, such as in response to an externally triggered local hyperthermia. Consequently, we prepared¹⁶ a panel of amino carbonyl substrates to

Fig. 1. Heat-induced cyclization via (a) lactamization or (b) carbonate formation.

determine factors that would minimize the rate of cyclization at 37 °C while allowing cyclization to proceed at higher temperature (Fig. 2).

2. Results and discussion

2.1. Cyclization panel (Fig. 2)

All substrates were prepared to contain an *N*-allyl moiety for convenient functionalization, such as hydrosilylation or thiol incorporation, for eventual covalent attachment to various supports.

NANOPARTICLES FOR DRUG DELIVERY

Cross Reference to Related Applications

This patent application claims the benefit of priority of U.S. application serial No. 61/762,832 filed February 8, 2013 and U.S. application serial No. 61/773,663 filed March 6, 2013, which applications are hereby incorporated by reference.

Statement of Government Support

This invention was made with state government support under Grant number 2190-RDE-013 awarded by the Kentucky Science and Engineering Foundation. The Commonwealth of Kentucky has certain rights in the invention.

Background

An important attribute of a drug delivery system is its ability to allow for spatial and temporal regulated drug release, thereby minimizing side effects and improving therapeutic efficacy of conventional pharmaceuticals. Iron oxide nanoparticles (NPs), specifically Fe₃O₄ nanoparticles, possess many appropriate qualities that make them a viable choice for drug delivery. Fe₃O₄ NPs are biocompatible (Kievit, F. M., et al., *Accounts of Chemical Research* 2011, 44 (10), 853-862), have low cytotoxicity (Bulte, J. W. M., et al., *NMR in Biomedicine* 2004, 17, 484-499), and provide multiple means for surface modification. Though these attributes are needed in a drug delivery vehicle, there are multiple different NPs that possess similar qualities including gold and silica. Fe₃O₄ is set apart from these NPs due to its paramagnetic or superparamagnetic (SPM) qualities (Yang, C., et al., *Chemical Communications* 2011, 47, 5130-5141). The SPM properties of Fe₃O₄ NPs have been used for a variety of applications. A basic utilization of SPM capability is to induce non-invasive hyperthermia within cancer cells. Alternating electromagnetic field (AMF)-induced Fe₃O₄ NPs heat body tissue to temperatures as high as 45 °C, and this causes cell death. In addition, when functionalized either by ionic interactions or through entrapment via a polymer gel coating, drugs can be guided to tumor regions through the use of a magnet, as first demonstrated by Meyers in 1963 (Meyers, P.H., et al., *American Journal of Roentgenology, Radium Therapy, and Nuclear Medicine* 1963, 90, 1068–1077). Through more advanced methods, Fe₃O₄ NPs are now extensively functionalized with complex delivery mechanisms and can be directed by taking advantage of tumor folate receptors (Kim, J., et al., *Advanced Materials* 2008, 20,

attributes are needed in a drug delivery vehicle, there are multiple different NPs that possess
similar qualities including gold and silica. Fe₃O₄ is set apart from these NPs due to its
paramagnetic or superparamagnetic (SPM) qualities (Yang, C., et al., *Chemical*
Communications **2011**, *47*, 5130-5141). The SPM properties of Fe₃O₄ NPs have been used
15 for a variety of applications. A basic utilization of SPM capability is to induce non-invasive
hyperthermia within cancer cells. Alternating electromagnetic field (AMF)-induced Fe₃O₄
NPs heat body tissue to temperatures as high as 45 °C, and this causes cell death. In addition,
when functionalized either by ionic interactions or through entrapment via a polymer gel
coating, drugs can be guided to tumor regions through the use of a magnet, as first
20 demonstrated by Meyers in 1963 (Meyers, P.H., et al., *American Journal of Roentgenology*,
Radium Therapy, and Nuclear Medicine **1963**, *90*, 1068-1077). Through more advanced
methods, Fe₃O₄ NPs are now extensively functionalized with complex delivery mechanisms
and can be directed by taking advantage of tumor folate receptors (Kim, J., et al., *Advanced*
Materials **2008**, *20*, 478-483, Zhang, Z., et al., *Biomaterials* **2007**, *28* (10), 1889-1899,
25 Zhang, L., et al., *International Journal of Pharmaceutics* **2004**, *287* (1-2), 155-162). Finally,
iron oxide also can be used as a magnetic resonance imaging contrast agent, so delivery
systems based on this material can be visualized (Lee, J. E.; et al., *Journal of the American*
Chemical Society **2010**, *132*, 552-557).

Some of the most common methods of functionalization or attachment of drug
30 payloads to Fe₃O₄ NPs involve the use of ionic attraction (Nantz, M. H., et al., *PCT Int. Appl.*
2011, WO 2011049972 A1 20110428), the addition of a mesoporous silica shell around the
Fe₃O₄ NPs followed by further functionalization of the silica (Meng, H., et al., A. E., *ACS*
Nano **2010**, *4* (8), 4539-4550, Lin, Meng M., et al., *Nano Reviews* **2010**, *1*, 4883) or the use

Keywords: **AMF, carbamates, covalent, hydrolysis, nanoparticles**

Abstract: Application of an alternating magnetic field (AMF) to magnetic core–shell iron oxide–silica nanoparticles fitted with short carbonate- or carbamate-functionalized chains that covalently link a fluorophore results in rapid functional group hydrolysis with attendant release of the fluorophore. This first example of AMF-induced carbamate hydrolysis resulted in *ca.* 10-fold greater release of fluorophore substrate in comparison to the control at 37 °C in the absence of an AMF.

1. Introduction

An important attribute of a drug delivery system is regulated spatial and temporal drug release to minimize side effects as well as to improve the therapeutic efficacy of conventional pharmaceuticals. Iron oxide nanoparticles (NPs) possess many features that make them a viable choice for drug delivery formulations. Magnetite (Fe₃O₄) NPs are biocompatible,^[1] have low cytotoxicity,^[2] can be readily surface-modified and have inherent paramagnetic or superparamagnetic properties.^[3] As a result of their magnetism, one highly-studied feature of Fe₃O₄ NPs is their ability to heat a surrounding environment

EDUCATION

- Ph.D.** **University of Louisville**, Department of Chemistry, Louisville, KY 2009-2014
Organic Chemistry (expected December 2014)
Thesis: Triggered Release of Small Molecules from Solid Supports
Using Heat or an Applied Magnetic Field
- B.S.** **Ohio Dominican University**, Columbus, OH 2003-2007
Chemistry (cumulative GPA: 3.786; degree awarded May 2007)

ACADEMIC AND INDUSTRIAL RESEARCH EXPERIENCE

University of Louisville, Department of Chemistry 2009-Present
Advisor: Dr. Michael H. Nantz

- Engineered and synthesized thermally labile linkers for substrate/drug release *via* intramolecular cyclization. Applied this technology to the chemoselective capture of carbonyls (aldehydes and ketones) utilizing aminooxy click-chemistry from a metabolite stream for FT-ICR-MS detection.
- Developed a drug delivery mechanism to release an active drug from iron oxide (Fe₃O₄) nanoparticles on the application of an external alternating magnetic field.
- Designed and optimized aminooxy probes for the early detection of lung cancer from exhaled breath using direct injection FT-ICR-MS, LC-MS and GC-MS conjunctively and without liquid-liquid extraction.
- Successfully planned and completed numerous multi-step syntheses, purifications and characterizations.

GFS Chemicals, Inc., Columbus, Ohio
Organic Chemist: Kilo Lab

2007-2009

- Specialized in synthesis of acetylenic, olefinic, silane and Grignard reagent building blocks on a 500 mL to 72 L multi-molar scale for multiple applications.
- Delivered products meeting customer specifications for custom syntheses, internal and external pilot plant development, as well as maintaining supplies of specific catalog items.
- Implemented several process improvements that remain incorporated into production activities today.
- Provided fast and accurate procedures and notes that were used to establish large-scale production methodologies and yields.

TEACHING SKILLS

Teaching Assistant: Organic Spectroscopy and Separations Lab (CHEM 527)
Department of Chemistry, University of Louisville; Fall 2012

FELLOWSHIPS and AWARDS

- Graduate Dean's Citation, University of Louisville, *School of Interdisciplinary Graduate Studies (SIGS)*, 2014
- Travel Award, University of Louisville, *Institute for Molecular Diversity and Drug Design* to attend Nanotech, Washington, D.C., 2013
- Research Fellowship, *Bill and Melinda Gates Foundation*, 2012-2013
- University Graduate Student Fellowship, University of Louisville, *School of Interdisciplinary Graduate Studies (SIGS)*, 2009-2011
- Outstanding Senior in Chemistry Award, Ohio Dominican University, *Division of Math, Computer and Natural Sciences*, 2007
- CRC Press Freshman Chemistry Award, Ohio Dominican University, *Division of Math, Computer and Natural Sciences*, 2004

PROFESSIONAL ACTIVITIES

- **Member**, Kentucky Academy of Science (2013)
- **Presenter**, Woodland Elementary School Career Day, Hardin County Schools (2013)
- **Treasurer Elect**, Columbus American Chemical Society (2009); **Active Member**
