#### Abstract

Sharing of substructures like subterms and subcontexts in terms is a common method for space-efficient representation of terms, which allows for example to represent exponentially large terms in polynomial space, or to represent terms with iterated substructures in a compact form. We present singleton tree grammars as a general formalism for the treatment of sharing in terms. Singleton tree grammars (STG) are recursion-free context-free tree grammars without alternatives for non-terminals and at most unary second-order nonterminals. STGs generalize Plandowski's singleton context free grammars to terms (trees). We show that the test, whether two different nonterminals in an STG generate the same term can be done in polynomial time, which implies that the equality test of terms with shared terms and contexts, where composition of contexts is permitted, can be done in polynomial time in the size of the representation. This will allow polynomial-time algorithms for terms exploiting sharing. We hope that this technique will lead to improved upper complexity bounds for variants of second order unification algorithms, in particular for variants of context unification and bounded second order unification.

Keywords: Sharing - tree grammars - polynomial word problem

## 1 Introduction

Sharing of substructures is a classic and ubiquitous method for efficient space usage in software systems. In Automated Deduction, sharing of subterms and subcontexts in terms is a common method for space-efficient representation of
terms, which allows for example to represent exponentially large terms in polynomial space, or to represent terms with iterated substructures in a compact form. An example is first-order unification Rob65 MM82, which is known to be polynomial, and where terms in a most general unifier may be exponentially large, but can be represented in linear space using sharing of subterms. In Automated Deduction Systems, methods like Coded Context Trees are used for compression and indexing of terms, which exploit term sharing and context sharing, however, without the possibility of composing contexts; see GNN04.

A first formalization of reasoning about sharing of words was done using a specialized form of grammars: Pla94 introduced a grammar formalism, now called singleton context free grammars (SCFG), which is a very convenient and rather general formalism for representing large words- using only sharing - in a compact form, and also for reasoning about complexity of algorithms on words with shared subwords. The grammars are non-recursive, have exactly one rule per non-terminal, and are Chomsky grammars, i.e. the right hand side of rules has at most length 2. Plandowski has proved that in an SCFG, the words $w_{A}, w_{B}$ represented by two nonterminals $A, B$, can be compared for equality in time polynomial in the size of the grammar. Usage of these grammars is called grammer compression (also straight-line program) in literature on word-compressing algorithms (see Ryt04). For example, $\left((a b)^{100} c^{20}\right)^{1000}$ is a specialized representation of a word of length 220000 , which can easily be represented (using sharing) by a nonterminal in an SCFG of polynomial size in the size of $\left((a b)^{100} c^{20}\right)^{1000}$, i.e. 16 . For example, Plandowski's theorem, resp. algorithm, can be applied to efficiently show that $\left((a b)^{300} a(b a)^{100} b\right)^{200}=(a b)^{80200}$, after an easy encoding.

Terms, also called ranked trees, generalize words. The notions of grammars and automata can also be generalized to terms (see e.g. $\left[\mathrm{CDG}^{+97}\right.$ ). In this paper we define singleton tree grammars (STGs) as a generalization of SCFG in order to have a general mechanism for a compressed representation of terms using sharing. We will employ the restriction that the arity of nonterminals is 0 or 1 , i.e. there are tree nonterminals, and context-nonterminals representing trees with a single hole. STGs are recursion-free context-free tree grammars without alternatives for non-terminals and at most unary second-order nonterminals. The right hand sides of rules are flat (second-order) terms, i.e the size is at most maxarity +1 , where maxarity is the maximal arity of a function symbol occurring in the grammar. Seen from a tree grammar view, we assume that there is only one bound variable in the term functions, and that the right hand sides of rules contain at most one occurrence of a bound variable, i.e., they are linear in the lambda-bound variable. In our formalism of STGs, these lambda-bound variable are not mentioned explicitly. The terms represented by an STG may be exponentially large and also exponentially deep.

The goal of this paper is to generalize Plandowski's theorem to singleton tree grammars (see Theorem 9.13), which states that the word problem for two tree nonterminals in an STG is solvable in polynomial time. The proof is given by generalizing Plandowski's algorithm to terms. This generalized algorithm uses expansion and compaction, which can also be used for STGs. The structure
of Plandowski's proof and several of Plandowski's lemmas can be transferred to STGs, however, there are far more cases and also new notions are to be introduced, e.g., a periodicity lemma for overlaps of a word $w$ with its singlepoint mutants has to be proved.

A planned future application of the theorem will be sharper upper complexity bounds for variants of second-order such as bounded second-order unification SS04 and algorithms for variants of context unification SS02SS01. We conjecture that the results are also extendible to contexts with several holes. It is unclear whether the result can be extended if nonlinear lambda terms are allowed in singleton tree grammars. We leave both issues for future work.

There are already methods to represent (sets of) terms in compact form using exponents: $\rho$-terms CH95, I-terms Com95, R-terms Sal92, and primal grammars HG97]. However, usually these representations are intended to represent infinite sets of terms and to support unification algorithms. Usually, these formalisms allow integer variables in terms instead of integers, which is more general than STGs, however, I-terms and R-terms do not allow nesting of exponents. The considered word problem is usually different from ours (see HS98). Our result can be applied to comparing I-terms for equality if the integer exponents are already instantiated, and may be applied in an estimation of the complexity of unification of I-terms. The result cannot be used for R-terms, since this would require that nonlinear lambda terms are permitted in the tree grammar formalism.

The paper is structured as follows. After recalling some basic definitions and singleton context free tree grammars and their properties, we introduce the singleton tree grammars in section 4 and explore some of their required properties in section 5 In section 6 we define sets of overlap-triples as data structure and in section 7 we define the for the algorithm WOPS solving the word problem efficiently. In sections 8 and 9 it is shown that the algorithm correctly solves the word problem and that it has the claimed polynomial complexity.

## 2 Preliminaries

Let $\Sigma$ be a finite signature of function symbols. Every function symbol comes with an arity, denoted $\operatorname{ar}(f)$, which is a nonnegative integer. The number maxarity is defined to be the maximal arity of function symbols in the signature $\Sigma$. Function symbols with $\operatorname{ar}(f)=0$ are also called constant symbols. We assume that the signature contains at least one constant symbol.
First-order terms (also called ranked trees) $t$ are formed using the grammar rule $t::=f\left(t_{1}, \ldots, t_{\operatorname{ar}(f)}\right)$ where $f$ is a function symbol of arity $n$, and $t_{i}$ for $i=1, \ldots, n$ are terms. For a constant symbol $a$, we write $a$ instead of $a()$. Terms are denoted using lower case letters $s, t$. We call $f$ the head of the term $t=f\left(t_{1}, \ldots, t_{\operatorname{ar}(f)}\right)$, denoted as head $(t)$. We will use words as tree addresses for pointing to subterms in a term, and call them positions. With $\operatorname{Pos}(t)$ we denote the set of positions of $t$. For $p \in \operatorname{Pos}(t)$, the subterm of $t$ at position $p$ is denoted as $t_{\mid p}$. The notation $t[s]_{p}$ means that $t$ has a subterm $s$ at position $p$. For words
$w_{1}, w_{2}$ we write $w_{1} \perp w_{2}$, iff neither $w_{1}$ is a prefix of $w_{2}$ nor $w_{2}$ is a prefix of $w_{1}$. We write $w_{1} \| w_{2}$, otherwise, i.e. iff $w_{1}$ is a prefix of $w_{2}$ or $w_{2}$ is a prefix of $w_{1}$.

A context $W$ is a first order term over the signature extended with a 0 ary constant, denoted $[\cdot]$, also called the hole, such that there is exactly one occurrence of the hole in $W$. Usually, contexts are denoted as $C[$.$] , or also simply$ as $C$. The term that results from plugging in the term $t$ in the hole of the context $C[$.$] is denoted as C[t]$. Similarly, we use this notation for contexts. i.e. the context that results from $C_{1}[$.$] by plugging in the context C_{2}[$.$] is denoted as C_{1}\left[C_{2}[].\right]$, or also as $C_{1} C_{2}$. The notation $C^{n}$ means $\underbrace{C \ldots C}_{n}$. Another view is that contexts are functions on terms, e.g. $C[$.$] is the function \lambda x . C[x]$, where we will always have the restriction that the body of the abstraction has exactly one occurrence of the bound variable $x$, i.e., is a linear term in $x$. With $m p\left(w_{C}\right)$ we denote the position of the hole in the context $C[$.$] ; this position is also called the main path of C$. The number $|m p C|$ is also called the main depth of $C$. With $\operatorname{Pos}(C)$ we denote the set of positions of $C$, excluding the position of the hole. If $p \in \operatorname{Pos}(C)$, the subcontext of $C$ at position $p$ is denoted as $C_{\mid p}$. In the case that $m p\left(w_{C}\right)$ is a prefix of $p$, we also permit the notation $C_{\mid p}$ and define $C_{\mid p}:=[\cdot]$.

A context $W$ can be seen as a word of length $|m p(W)|$ by representing it as a concatenation of $\left|m p\left(w_{C}\right)\right|$ contexts of main depth 1 . So we can use definitions, tools and properties for words also for contexts. A context $W$ has a period $v$, if $W$, seen as a word, has the period $v$, i.e., there is a context $W^{\prime}$ with $\left|m p\left(W^{\prime}\right)\right|=v$, and $W$ is a subword of $\left(W^{\prime}\right)^{n}$, for some appropriate positive integer $n$. This definitions makes only sense, if $v<|m p(W)|$.

From Lot83] we see that the following holds:
Lemma 2.1. If a context $W$ has two periods $v_{1}, v_{2}$ with $v_{1}+v_{2} \leq|m p(W)|$, then $W$ has also a period $\operatorname{gcd}\left(v_{1}, v_{2}\right)$.

Given a signature $\Sigma$ of functions symbols and a set $\Sigma^{(2)}$ of unary second-order symbols, we define also second-order terms as follows: $t::=f\left(t_{1}, \ldots, t_{n}\right) \mid X(t)$, where $f$ is an $n$-ary function symbol from $\Sigma$, and $X$ a second-order symbol in $\Sigma^{(2)}$. Using the hole [.] as a constant, we can form second order terms containing this hole. Throughout this paper, we allow only one occurrence of [.] in a second order term. Second order terms containing a single constant [.] are also called second order context terms.

If we speak of "terms" in the following, we always mean first order terms; if we mean second order terms, this is mentioned explicitly.

## 3 Singleton Context Free Grammars

We repeat the definitions and results of Plandowski Pla94].

### 3.1 Singleton Context Free Grammars and Plandowski's Theorem

Definition 3.1. A singleton context free grammar (SCFG) is a $C F G G=$ $(\mathcal{T}, \mathcal{N}, R)$ where $\mathcal{T}$ are the terminals, $\mathcal{N}$ are the nonterminals with $\mathcal{N} \cap \mathcal{T}=\emptyset$,
and $R \subseteq \mathcal{N} \times(\mathcal{T} \cup \mathcal{N})^{*}$ are the rules, such that the right hand sides of $R$ are words of length $\leq 2$. For every nonterminal $N$, there is exactly one rule in $R$ of the form $N \rightarrow t$. The grammar must be non-recursive. More formally, the relation $\xrightarrow{+}$ has no cycles, where $\xrightarrow{+}$ is the transitive closure of the relation $\rightarrow \subseteq \mathcal{N} \times \mathcal{N}$, where $N \rightarrow M$ iff there is a rule $N \rightarrow t \in R$ where $M$ occurs in $t$.

The word generated by a non-terminal $N$ is denoted as $w_{G, N} \in \mathcal{T}^{*}$. If the grammar is clear from the context, we drop the suffix $G$. We extend the notation $w_{N}$ to arbitrary words $\alpha \in(\mathcal{T} \cup \mathcal{N})^{*}$ such that $w_{\varepsilon}=\varepsilon$, $w_{a}=$ a for terminals $a$, and $w_{a_{1} \ldots a_{n}}=w_{a_{1}} \ldots w_{a_{n}}$.

Note that the start-symbol is omitted in the definition, since we are interested in the words generated by each non-terminal.

Theorem 3.2. Given an $S C F G G$, and two nonterminals $N_{1}, N_{2}$. Then it is decidable in polynomial time in the size of $G$, whether $w_{N_{1}}=w_{N_{2}}$.

Proof. In Pla94.

An equivalent formulation is to have two different grammars $G_{1}, G_{2}$ and a nonterminal $N_{i}$ from $G_{i}$ for $i=1,2$, and asking whether $N_{1}, N_{2}$ define the same word.

Example 3.3. Given a language for representing words with the syntax $P::=a|b| P^{n}|(P)| P P$
where $a, b$ are terminals, and $n$ is a positive integer, it is possible to write $a^{1000}$ to represent a word $\underbrace{a \ldots a}_{1000}$. More involved examples are $a b^{100}\left(a b^{100} a\right)^{15}$. Testing equality of the represented words takes exponential time if the comparison is done by first expanding them. A nontrivial test which should succeed is for example whether $(a b)^{100} a=a(b a)^{100}$.
It is easy to encode this equality test in a small SCFG, such that the number of rules is polynomial in the printed size of this equation (which is 21 for this equation). E.g.: $a^{1000}$ can be encoded along its representation as binary number 1111101000 using the rules $N_{1}::=a, N_{2}::=N_{1} N_{1}, N_{3}::=N_{2} N_{2}, \ldots, N_{9}::=$ $N_{8} N_{8}, M_{9}::=N_{9} M_{8}, M_{8}::=N_{8} M_{7}, M_{7}::=N_{7} M_{6}, M_{6}::=N_{6} M_{5}, M_{5}::=$ $N_{5} N_{3}$. The nonterminal $M_{5}$ encodes $a^{1000}$. After the appropriate encoding, Theorem 3.2 assures us that equality tests are possible in polynomial time.

Definition 3.4. The size of an $S C F G G$ is the number of its rules and denoted as $|G|$.
The depth $(D)$ of a nonterminal $D$ is defined as:
$\operatorname{depth}(D):=1+\max \left(\operatorname{depth}\left(D_{1}\right)\right.$, depth $\left.\left(D_{2}\right)\right)$ if the rule for $D$ is $D=D_{1} D_{2}$. The depth of $G$ is the maximum of the depths of all its nonterminals.

### 3.2 Operations on Singleton Context Free Grammars

In this section we define several operations on an SCFG $G$, which may be tests for specific properties, or extending the grammar, and we also explore the complexity of these operations.

Definition 3.5. An extension of an $S C F G G=(\mathcal{T}, \mathcal{N}, R)$ is a $S C F G G^{\prime}=$ $\left(\mathcal{T}^{\prime}, \mathcal{N}^{\prime}, R^{\prime}\right)$ with $\mathcal{T} \subseteq \mathcal{T}^{\prime}, \mathcal{N} \subseteq \mathcal{N}^{\prime}$, and $R \subseteq R^{\prime}$.

An extension of an $S T G(\mathcal{T N}, \mathcal{C N}, \Sigma, R)$ is a $S T G G^{\prime}=\left(\mathcal{T N}{ }^{\prime}, \mathcal{C N}^{\prime}, \Sigma^{\prime}, R^{\prime}\right)$ with $\mathcal{T} \mathcal{N} \subseteq \mathcal{T} \mathcal{N}^{\prime}, \mathcal{C N} \subseteq \mathcal{C} \mathcal{N}^{\prime}, \Sigma \subseteq \Sigma^{\prime}$, and $R \subseteq R^{\prime}$.

Extending the grammar during the run of an algorithm and estimating the size increase has to be done carefully, since a polynomial size increase in every step is in general too large.

Lemma 3.6. Given an SCFG G, a nonterminal $N$, and a number $0<n<$ $\left|w_{N}\right|$, an extension $G^{\prime}$ of $G$ can be constructed in polynomial time in $|G|$, such that $G^{\prime}$ contains a nonterminal $N^{\prime}$ such that $\left|N^{\prime}\right|=n$, and $w_{N^{\prime}}$ is a suffix (or a prefix, respectively) of $w_{N}$. Moreover, $\left|G^{\prime}\right| \leq|G|+\operatorname{depth}(G)$, $\operatorname{depth}\left(G^{\prime}\right)=$ depth $(G)$.

Proof. See LSSV04.
Lemma 3.7. Given an SCFG $G$, a nonterminal $N$, and a number $n>0$, an extension $G^{\prime}$ of $G$ can be constructed in polynomial time in $|G|$ and $\log (n)$, such that $G^{\prime}$ contains a nonterminal $N^{\prime}$ and $w_{N^{\prime}}=w_{N}{ }^{n}$. Moreover, $\left|G^{\prime}\right| \leq$ $|G|+2 *\lceil\log (n)\rceil$, depth $\left(G^{\prime}\right) \leq \operatorname{depth}(G)+\lceil\log (n)\rceil$.
Proof. See LSSV04.
Lemma 3.8. Given an $S C F G G$, nonterminals $N_{1}, \ldots, N_{n}$, an extension $G^{\prime}$ of $G$ can be constructed in polynomial time in $|G|$ and $n$, such that $G^{\prime}$ contains a nonterminal $N^{\prime}$ such that $w_{N^{\prime}}=w_{N_{1}} \ldots w_{N_{n}}$. Moreover, $\left|G^{\prime}\right| \leq|G|+n-1$, $\operatorname{depth}\left(G^{\prime}\right)=\operatorname{depth}(G)+\lceil\log (n)\rceil$.
Proof. See LSSV04.
Lemma 3.9. Given an SCFG $G$ and two nonterminals $N_{1}, N_{2}$, the following tests are polynomial in $|G|$ :
$-w_{N_{1}}$ is a prefix of $w_{N_{2}}$.
$-w_{N_{1}} \perp w_{N_{2}}$.
$-w_{N_{1}} \| w_{N_{2}}$.
Proof. It is sufficient to prove the first claim. The other claims can be derived immediately. As already proved in Pla94, the computation of $\left|w_{a}\right|$ can be done in polynomial time. Given $N_{1}, N_{2}$, we compute the lengths $\left|w_{N_{1}}\right|$ and $\left|w_{N_{2}}\right|$. If $\left|w_{N_{1}}\right|>\left|w_{N_{2}}\right|$, then $\left|w_{N_{1}}\right|$ cannot be a prefix of $\left|w_{N_{2}}\right|$. Otherwise, construct an extension of the grammar $G$ that contains a nonterminal $N_{3}$ such that $w_{N_{3}}$ is a prefix of $w_{N_{2}}$ and $\left|w_{N_{3}}\right|=\left|w_{N_{1}}\right|$. This is possible in polynomial time due to Lemma 3.6, and the size of the new STG is at most polynomial in the size of $G$. Then we compare $w_{N_{1}}$ and $w_{N_{3}}$, which can also be done in polynomial time due to Theorem 3.2

## 4 Singleton Tree Grammars

We define singleton tree grammars as a generalization of singleton CFGs. We consider languages of ranked trees and extend the expressivity of SCFGs by permitting contexts. The definition is consistent with the context free tree grammars in [CDG ${ }^{+} 97$ ], however a special case.

Definition 4.1. A singleton tree grammar (STG) is a tree grammar, i.e. a 4-tuple $(\mathcal{T} \mathcal{N}, \mathcal{C N}, \Sigma, R)$, where $\mathcal{T \mathcal { N }}$ are tree nonterminals, $\mathcal{C N}$ are context nonterminals, and $\Sigma$ is a signature of function symbols (the terminals), such that the sets $\mathcal{T} \mathcal{N}, \mathcal{C N}, \Sigma$ are pairwise disjoint. The set of nonterminals $\mathcal{N}$ is defined as $\mathcal{N}=\mathcal{T} \mathcal{N} \cup \mathcal{C N}$. The rules in $R$ may be of the form:
$-A::=f\left(A_{1}, \ldots, A_{n}\right)$, where $A, A_{i}$ are tree non-terminals, and $f \in \Sigma$ is an n-ary function symbol.

- $A_{1}::=C\left[A_{2}\right]$ where $A_{1}, A_{2}$ are tree nonterminals and $C$ is a context nonterminal.
$-C_{1}::=C_{2} C_{3}$, where $C_{i}$ are context non-terminals.
$-C::=f\left(A_{1}, \ldots, A_{i-1},[\cdot], A_{i+1}, \ldots, A_{n}\right)$, where $A_{i}$ are tree nonterminals, $C$ is a context non-terminal, $[\cdot]$ is the hole, and $f \in \Sigma$ an n-ary function symbol.

The tree grammar must be non-recursive. More formally, the relation $\xrightarrow{+}$ has no cycles, where $\xrightarrow{+}$ is the transitive closure of the relation $\rightarrow \subseteq \mathcal{N} \times \mathcal{N}$, where $N \rightarrow M$ iff there is a rule $N \rightarrow t \in R$ where $M$ occurs in $t$.

Furthermore, for every non-terminal $N$ there is exactly one rule having $N$ as left hand side.
The derivation using the rules is performed for second order terms over a signature $\Sigma \cup \mathcal{T} \mathcal{N}$, where the tree nonterminals have zero arity, and a second order signature $\mathcal{C N}$. The derivation starts with $A$ as second order term, where $A$ is a tree nonterminal, or with the second order context term $C([]$.$) , where C$ is a context nonterminal. The rules are used in the derivation process as follows.

- If $A::=f\left(A_{1}, \ldots, A_{n}\right)$ or $A::=C\left[A^{\prime}\right]$, then $A$ in a second order term or second order context term is replaced by $f\left(A_{1}, \ldots, A_{n}\right)$, or $C\left(A^{\prime}\right)$, respectively.
- If $C_{1}::=C_{2} C_{3}$, then $C_{1}(s)$ in a second order term or or second order context term is replaced by $C_{2}\left(C_{3}(s)\right)$.
- If $C::=f\left(A_{1}, \ldots, A_{i-1},[\cdot], A_{i+1}, \ldots, A_{n}\right)$, then $C(s)$ in a term or context is replaced by $f\left(A_{1}, \ldots, A_{i-1}, s, A_{i+1}, \ldots, A_{n}\right)$.

The derivation process stops if there are no more replacement possibilities, and the result is either a first order term or a context. We write $\alpha \rightarrow_{G} \beta$ if there is a derivation starting with the second order term $\alpha$ and reaching the second order term $\beta$. Given a non-terminal $A$, or $C$, respectively, of $G$, by $w_{G, A}$ or $w_{G, C}$ we denote the generated first order term or first order context, respectively. More general, if $t$ is a second order term or a second order context term over the signature given above, then $w_{G, t}$ is the generated first order term or the context, respectively. If the grammar $G$ is clear, we omit the suffix in our notation. We also may use the notation $m p\left(w_{C}\right)$ as a short hand for $m p\left(w_{C}\right)$.

Note that we omit the rules of the form $A::=A^{\prime}, C::=C^{\prime}, C::=[\cdot]$ in the definition, since these rules can easily be eliminated (see Remark 4.4).

Definition 4.2. The size of a grammar (STG) $G$ is the number of its rules and denoted as $|G|$.
The depth $(D)$ of a nonterminal $D$ is defined as:
$-\operatorname{depth}(D):=1+\max \left(\operatorname{depth}\left(D_{1}\right)\right.$, depth $\left.\left(D_{2}\right)\right)$ if the rule for $D$ is $D=D_{1} D_{2}$ or $D_{1}\left[D_{2}\right]$.
$-\operatorname{depth}(D):=1+\max \left\{\operatorname{depth}\left(A_{j}\right) \mid j=1, \ldots, n\right\}$ if the rule for $D$ is $D=$ $f\left(A_{1}, \ldots, A_{n}\right)$, where we presume that the depth of the hole [.] is zero and the maximum over an empty set is 0 .

The depth of a grammar is the maximum of the depths of all nonterminals.
In an $\operatorname{STG} G$, we write $A>B$, iff one of the following holds: $A \in \mathcal{T N}$, $A \xrightarrow{+} \alpha$ for a second-order term $\alpha$, and $B$ occurs in $\alpha$; or $A \in \mathcal{C N}, A([].) \xrightarrow{+} \alpha$ for a second-order context term $\alpha$, and $B$ occurs in $\alpha$.

Example 4.3. If $C$ is the context $C=f(g(x),[\cdot], h(x))$, then the term $C^{100}(b)$ can be represented using a singleton tree grammar as follows:

$$
\begin{array}{lll} 
& C_{1}::=C_{0} C_{0} & \\
C_{0}::=f\left(A_{1},[\cdot], A_{2}\right) & C_{2}::=C_{1} C_{1} & D_{1}::=C_{6} C_{5} \\
A_{1}::=g\left(A_{3}\right) & C_{3}::=C_{2} C_{2} & D_{2}::=D_{1} C_{2} \\
A_{2}::=h\left(A_{3}\right) & C_{4}::=C_{3} C_{3} & B::=b \\
A_{3}::=x & C_{5}::=C_{4} C_{4} & D_{3}::=D_{2}[B] \\
& C_{6}::=C_{5} C_{5} &
\end{array}
$$

The nonterminal $D_{3}$ represents the term

$$
f(g(x), f(g(x), f(\ldots(b) \ldots), h(x)), h(x))
$$

where the nesting depth is 100 . In an exponent notation for contexts as unary functions with $C \equiv \lambda z \cdot f(g(x), z, h(x))$, it could be represented as $C^{100}(b)$.

The goal is to prove the following theorem (see Theorem 9.13).
Theorem Given an STG $G$, and two tree nonterminals $A, B$ from $G$, it is decidable in polynomial time depending on $|G|$ whether $w_{A}=w_{B}$.

The proof will be given in the following sections.
An equivalent problem is the question, given two different STGs $G_{1}, G_{2}$ and $N_{i}$ from $G_{i}$ for $i=1,2$, whether $w_{N_{1}}=w_{N_{2}}$.

Remark 4.4. Note that it would be possible to permit more kinds of rules in an STG. Suppose we also allow rules of the form:
$-C_{1}::=C_{2}$.
$-A_{1}::=A_{2}$.
$-C_{1}::=[\cdot]$.

These rule formats allow a more compact representation of the terms in certain cases.

The first two kinds of rules can be eliminated by replacing e.g. the rule $C_{1}::=C_{2}$ by the rule $C_{1}::=W$, where $C_{2}::=W$ is the rule for $C_{2}$. Similarly for the second rule. The complexity will slightly increase, since there may be a size increase of $O\left(|G|^{2}\right)$. The third rule is irrelevant for the worst case complexity of the word problem.

## 5 Operations on Singleton Tree Grammars Using SCFGs for Positions

Lemma 5.1. Given an $S T G G$ and a nonterminal $D$ from $G$. Then head $\left(w_{D}\right)$ can be computed in polynomial time in $|G|$.

Proof. The grammar is nonrecursive. Thus the number of steps is at most depth $(G)$, since in the right hand sides of rules only $C[A]$ and $C C^{\prime}$ are nontrivial, and only $C$ needs to be further expanded.

Corollary 5.2. Given an $S T G G$ and two nonterminals $D_{1}, D_{2}$ from $G$. Then the test head $\left(w_{D_{1}}\right)=$ head $\left(w_{D_{2}}\right)$ can be performed in polynomial time in $|G|$.

Definition 5.3. Given an $S T G G$, an $S C F G G^{\prime}$ with positive integers as terminals, and a (partial) injective mapping $\mathcal{C} \mathcal{N}_{G} \rightarrow \mathcal{N}_{G^{\prime}}$, such that $C \mapsto C_{s}$ for every context nonterminal. If $m p\left(w_{G, C}\right)=w_{G^{\prime}, C_{s}}$ for every $C \in \mathcal{C} \mathcal{N}_{G}$, then $G^{\prime}$ is called a position grammar of $G$.

Definition 5.4. Given an $S T G G$. Then we define an $S C F G G_{p G}$ with positive integers as terminals, as follows:
For every context nonterminal $C$ in $G$, there is a unique nonterminal $C^{\prime}$ in $G_{p G}$. The rules are as follows:
$-C^{\prime}::=i$ if $C::=f\left(A_{1}, \ldots, A_{i-1},[\cdot], A_{i+1}, \ldots, A_{n}\right)$ is a rule in $R_{G}$.
$-C^{\prime}::=C_{1}^{\prime} C_{2}^{\prime}$ if $C::=C_{1} C_{2}$ is a rule in $R_{G}$.
Lemma 5.5. Given an $S T G G$, then $G_{p G}$ can be constructed in polynomial time.
Moreover, $G_{p G}$ is a position grammar of $G$.
Proof. By induction.
Lemma 5.6. Given an $S T G G$ and a position grammar $G_{s}$. For a nonterminal $D$ from $G$ and a nonterminal $N$ from $G_{s}$ the test whether $w_{N} \in \operatorname{Pos}\left(w_{D}\right)$ can be performed in polynomial time in $|G|$ and $\left|G_{s}\right|$.

Proof. We show that a recursive algorithm using smaller and smaller STGs $G$ has at most $|G|$ recursions and every step is polynomial. Let $d=\operatorname{depth}(G)$.

- Consider the case that $D$ is a context nonterminal. Then the nonterminal $N_{D}$ corresponding to $D$ is already in $G_{s}$. The computation of a nonterminal $N_{1}$ representing the longest common prefix of $w_{N}$ and $w_{N_{D}}$, a number $k$, and a nonterminal $N_{2}$ representing the suffix, such that $w_{N_{1}} k w_{N_{2}}=w_{N}$ can be done in polynomial time giving $G_{s}^{\prime}$ with $\left|G_{s}^{\prime}\right| \leq\left|G_{s}\right|+2 * d$. Determining the right hand side component in $G$, where the derivation starting from $D$ forks for $N$ and $N_{D}$, can be done in polynomial time and results in a component $f\left(A_{1}, \ldots, A_{i-1},[\cdot], A_{i+1}, \ldots, A_{n}\right)$, and a number $k \neq i$. Then the computation can proceed recursively using a smaller grammar $G^{\prime}$ of all nonterminals necessary to define the tree nonterminal $A_{k}$, and the nonterminal $N_{2}$.
- Let $D$ be a tree nonterminal. Then either $D::=f\left(A_{1}, \ldots, A_{n}\right)$, and we can argue as above. If $D::=C[A]$, then again we can compare $N$ with the nonterminal $C_{s}$ for $m p\left(w_{C}\right)$. If $m p\left(w_{C}\right)$ is a prefix of $w_{N}$, then we construct a suffix nonterminal $N_{1}$ with $w_{N}=m p\left(w_{C}\right) w_{N_{1}}$, and use then the same algorithm for $A$ and $N_{1}$. If $m p\left(w_{C}\right) \perp w_{N}$, we call the same procedure using $C$ and $N$.

It is clear that the number of recursive calls is at most $|G|$, since in every call at least one rule can be removed from the current $G$. Hence the size of the final $G_{s}^{\prime \prime}$ is at most $\left|G_{s}\right|+2|G| * d \leq\left|G_{s}\right|+2|G|^{2}$. Thus there is a size increase that is overall bounded by a polynomial, all intermediate steps are polynomial. We can estimate the sum of all steps and obtain a polynomial upper bound in $|G|$ and $\left|G_{s}\right|$.

## 6 Triples for a Representation of Overlappings

We define overlay triples as a data structure for the algorithm solving the word problem of STGs.

Definition 6.1. Two contexts or trees $W_{1}, W_{2}$ have a top-overlap, iff for every position $p \in \operatorname{Pos}\left(W_{1}\right) \cap \operatorname{Pos}\left(W_{2}\right)$ : head $\left(\left.W_{1}\right|_{p}\right)=\operatorname{head}\left(\left.W_{2}\right|_{p}\right)$, i.e. the function symbols at all common positions are the same, where the position of the hole and the positions below the hole of contexts are ignored.

Definition 6.2. Let $G$ be a $S T G$, and let $G_{s}$ be a position grammar of $G$. A triple (wrt. $G$ and $G_{s}$ ) is either of the form $(A, B, \varepsilon)$ or of the form $(A, B, N)$ where $A, B$ are non-terminals from $G$, and $N$ is a non-terminal in $G_{s}$. A triple $(A, B, N)$ is well-formed, iff $w_{N} \in \operatorname{Pos}\left(w_{B}\right)$, or if $w_{B}$ is a context and $m p\left(w_{B}\right)$ is a prefix of $w_{N}$. Triples $(A, B, \varepsilon)$ are always well-formed.
A well-formed triple $(A, B, N)$ is valid, iff $\left(w_{B}\right)_{\mid w_{N}}$ and $w_{A}$ have a top-overlap.

Definition 6.3. Assume given an $S T G G$ and a position grammar $G_{s}$. The valid triples are partitioned into the following classes:
$-\varepsilon$-triples: triples of the form $\left(D_{1}, D_{2}, \varepsilon\right)$.

- inclusion triples: Triples of the form $\left(D_{1}, D_{2}, N\right)$, such that one of the following holds:

1. $D_{2}$ is a tree nonterminal, or
2. $D_{2}$ is a context non-terminal with $w_{N} \perp m p\left(w_{D_{2}}\right)$.
3. $D_{2}$ is a context non-terminal with $w_{N} \| m p\left(w_{D_{2}}\right)$, and $w_{N} m p\left(w_{D_{1}}\right)$ is a prefix of $m p\left(w_{D_{2}}\right)$.

- overlay triples: $(D, C, N)$, where $C$ is a context nonterminal, $w_{N} \| m p\left(w_{C}\right)$, and one of the following holds:

1. $D$ is a tree nonterminal $((D, C, N)$ is a tree overlay triple), or
2. $D$ is a context nonterminal, and $w_{N} m p\left(w_{D}\right)$ is not a prefix of $m p\left(w_{C}\right)$.

These are further distinguished into

- parallel overlay triples, if $m p\left(w_{C}\right) \| w_{N} m p\left(w_{D}\right)$.
- orthogonal overlay triples, if $m p\left(w_{C}\right) \perp w_{N} m p\left(w_{D}\right)$.

We say that the $\varepsilon$-triples and the inclusion triples are transient triples, since the algorithm WOPS will try to eliminate them first. The nontransient triples are the overlay triples.

We illustrate the parallel and orthogonal overlay triple $(D, C, N)$. From left to right, the first two diagrams show a parallel overlay triple, a full tree picture and a picture showing only the main paths, whereas the third and fourth shows the same for an orthogonal

We also order triples:
Definition 6.4. For $i=1, \ldots, 4$ let $D_{i}$ be nonterminals in an $S T G G$. Given two pairs $\left(D_{1}, D_{2}\right)$ and $\left(D_{3}, D_{4}\right)$, we say $\left(D_{1}, D_{2}\right)>\left(D_{3}, D_{4}\right)$, iff $D_{1} \geq D_{3}$, $D_{2} \geq D_{4}$ and one of the two relations is strict, where the base ordering is the derivation ordering w.r.t. $G$ (see Definition 4.1).
Given two triples $\left(D_{1}, D_{2}, N\right)$ and $\left(D_{3}, D_{4}, N^{\prime}\right)$, we write $\left(D_{1}, D_{2}, N\right)>$ $\left(D_{3}, D_{4}, N^{\prime}\right)$, iff $\left(D_{1}, D_{2}\right)>\left(D_{3}, D_{4}\right)$ or $\left(D_{1}, D_{2}\right)>\left(D_{4}, D_{3}\right)$.

Note that the ordering is exactly the multiset-ordering for $\left\{D_{1}, D_{2}\right\}$ and $\left\{D_{3}, D_{4}\right\}$ with base ordering $>$ on nonterminals.

## 7 The Algorithm WOPS

In this section we define the algorithm WOPS for solving an equation $N_{1}=N_{2}$ of nonterminals of an STG using transformation rules. The data structure is
mainly a set of triples. However, for control purposes, the triples are partitioned into different sets.

The main algorithmic parts are:

- straightforward unfolding of triples by transformations, however controlled by a strategy.
- Simplification rules for triples
- Failure Rules for compaction.
- Compaction rules for overlay triples

Definition 7.1. The algorithm WOPS has as input an STG $G$ and two tree nonterminals $N_{1}, N_{2}$. It has as state a tuple $\left(G_{s}, S_{\varepsilon, \text { closed }}, S_{\varepsilon, \text { open }}, S_{\text {not }}, S_{o t}\right)$, consisting of a singleton context free grammar $G_{s}$ as position grammar of $G$, a set $S_{\varepsilon, \text { closed }}$ of $\varepsilon$-triples already expanded, a set $S_{\varepsilon, \text { open }}$ of $\varepsilon$-triples not yet expanded, a set $S_{n o t}$ containing the inclusion triples, and a set $S_{o t}$ of overlay triples.

1. The initial state is $\left(G_{p G}, \emptyset,\left\{\left(N_{1}, N_{2}, \varepsilon\right)\right\}, \emptyset, \emptyset\right)$, where $G_{p G}$ is the position grammar of $G$ (see Definition 6.2), and $N_{1}, N_{2}$ are the tree nonterminals that have to be compared for equality.
2. Halting The algorithm WOPS returns "YES", i.e. it halts with success, if there are no more triples to be selected, i.e., if $S_{\varepsilon, \text { open }}=S_{o t}=S_{n o t}=\emptyset$. It halts with failure (i.e., returns " $N O$ "), if an explicit Fail is the result of a simplification or transformation.
3. Apply the simplification rules in subsection 7.1 and the failure rules in subsection 7.3 exhaustively.
4. Apply the compaction rules in subsection 7.4 exhaustively.
5. Apply a transformation rule according to the following strategy:

A triple $T$ is selected from one of the sets in the state according to the following priorities:

- $S_{n o t}$,
- $S_{\varepsilon, \text { open }}$
- $S_{o t}$, where a maximal triple according to Definition 6.4 in $S_{o t}$ has to be selected.
After the selection, the following is performed:
If $T \in S_{n o t} \cup S_{o t}$, then $T$ will be removed from each set.
If $T \in S_{\varepsilon, \text { open }}$, then it will be removed from $S_{\varepsilon, \text { open }}$ and added to $S_{\varepsilon, \text { closed }}$.
The selected triple $T$ will then be subject to a transformation as defined below in subsection 7.2, which may extend the singleton grammar $G_{s}$ to $G_{s}^{\prime}$. If the triples $T_{1}, \ldots, T_{n}$ are the outcome of the transformation, then do the following for each triple $T_{i}$ :
- If $T_{i}$ is an $\varepsilon$-triple, and $T_{i} \in S_{\varepsilon, \text { open }} \cup S_{\varepsilon, \text { closed }}$, then do nothing, otherwise add it to the set $S_{\varepsilon, \text { open }}$.
- Otherwise, if $T_{i}$ is an overlay triple, then add it to $S_{o t}$.
- Otherwise, if $T_{i}$ is an inclusion triple, then add it to $S_{\text {not }}$.

6. For iterating this cycle, go to step 2

### 7.1 The Transformation Rules of the Algorithm WOPS

First we define simplification rules on the state.

Simplification Rules The simplification rules operate on the state. The simplification rules are tested in the stated sequence, i.e. the simplification rule $j^{\prime}$ is applied only if the simplification rules $j<j^{\prime}$ are not applicable.
We write $D, D_{i}$ if we mean a tree or context nonterminal.

1. If there is some $\left(D_{1}, D_{2}, \varepsilon\right) \in S_{\varepsilon, \text { open }}$ with $\operatorname{head}\left(w_{D_{1}}\right) \neq \operatorname{head}\left(w_{D_{2}}\right)$, then Fail: The initial equation is False.
2. Remove $(D, C, N)$ from $S_{o t}$ or $S_{n o t}$, if $m p\left(w_{C}\right)$ is a prefix of $w_{N}$.
3. If there is some $\left(D_{1}, D_{2}, N\right) \in S_{o t} \cup S_{n o t}$ such that $w_{N} \notin \operatorname{Pos}\left(w_{D_{2}}\right)$, then Fail: The initial equation is False.
4. If there is some $\left(D_{1}, D_{2}, N\right) \in S_{o t} \cup S_{n o t}$ with head $\left(\left.w_{D_{2}}\right|_{w_{N}}\right) \neq \operatorname{head}\left(w_{D_{1}}\right)$, then Fail: The initial equation is False.
5. If there is some $(A, B, N) \in S_{o t} \cup S_{n o t}$, where $w_{A}$ or $w_{B}$ is a constant, then remove this triple from $S_{o t} \cup S_{n o t}$. If there is a triple $(A, B, \varepsilon) \in S_{\varepsilon, \text { open }}$, where $w_{A}$ or $w_{B}$ is a constant, then move it to $S_{\varepsilon, \text { closed }}$.

### 7.2 Transformation Rules

We assume that the simplification rules are applied exhaustively to the state before the transformation rules are applied.
Note that in the following rules, the notation $(A, B, N)$ means that $w_{N} \neq \varepsilon$. The main case distinction are four cases, depending on the types of the nonterminals in the triples: (tree, tree), (tree, context), (context, context) and (context, tree). In some cases, the position grammar $G_{s}$ is extended to a new position grammar $G_{s}^{\prime}$, since a new nonterminal has to be constructed. In the following we use diagrams for illustrating the relation of the main path of contexts and a position nonterminal. Usually, this is sufficient to understand and analyse the possibilities, ignoring the rest of the context.

- (T,T)-case. An illustration of the cases 4 to 6 is:

1. $(A, B, \varepsilon) \rightarrow\left\{\left(A_{1}, B, N_{1}\right), \ldots,\left(A_{k}, B, N_{k}\right)\right\}$ if $A::=f\left(A_{1}, \ldots, A_{k}\right)$, where $G_{s}^{\prime}$ contains the nonterminals $N_{1}, \ldots, N_{k}$ with rules $N_{i}::=i$ for $i=$ $1, \ldots, k$. Note that due to simplification, $\operatorname{ar}(f)>0$.
2. $(A, B, \varepsilon) \rightarrow\left\{(C, B, \varepsilon),\left(A^{\prime}, B, N\right)\right\}$ if $A::=C\left[A^{\prime}\right]$, where $N$ is the nonterminal in $G_{s}$ with $w_{N}=m p\left(w_{C}\right)$.
3. $(A, B, N) \rightarrow\left(A, B_{i}, N^{\prime}\right)$ if $B::=f\left(B_{1}, \ldots, B_{k}\right)$, and $w_{N}=i w_{N^{\prime}}$, where $N^{\prime}$ is a nonterminal in $G_{s}^{\prime}$.
4. $(A, B, N) \rightarrow(A, C, N)$ if $B::=C\left[B^{\prime}\right]$, and $w_{N} \perp m p\left(w_{C}\right)$.
5. $(A, B, N) \rightarrow\left\{(A, C, N),\left(B^{\prime}, A, N^{\prime}\right)\right\}$ if $B::=C\left[B^{\prime}\right]$, and $w_{N}$ is a proper prefix of $m p\left(w_{C}\right)$, where $N^{\prime}$ is a nonterminal in $G_{s}^{\prime}$ with $w_{N} w_{N^{\prime}}=$ $m p\left(w_{C}\right)$, otherwise.
6. $(A, B, N) \rightarrow\left(A, B^{\prime}, N^{\prime}\right)$ if $B::=C\left[B^{\prime}\right]$, and $m p\left(w_{C}\right)$ is a prefix of $w_{N}$, where $N^{\prime}=\varepsilon$ if $w_{N}=m p\left(w_{C}\right)$, or $N^{\prime}$ is a nonterminal in $G_{s}^{\prime}$ with $w_{N}=m p\left(w_{C}\right) w_{N^{\prime}}$.
7. $(A, A, N) \rightarrow$ Fail if $w_{N} \neq \varepsilon$.

- (T,C)-case. An illustration of the cases 4 to 6 is:

1. $(A, C, \varepsilon) \rightarrow\left\{\left(A_{1}, C, 1\right), \ldots,\left(A_{n}, C, n\right),\right\}$ if $A::=f\left(A_{1}, \ldots, A_{n}\right)$.
2. $(A, C, \varepsilon) \rightarrow\left\{\left(C_{2}, C, \varepsilon\right),\left(A^{\prime}, C, N\right)\right\}$ if $A::=C_{2}\left[A^{\prime}\right]$, where $N$ is the nonterminal in $G_{s}$ with $w_{N}=m p\left(w_{C_{2}}\right)$.
3. $(A, C, N) \rightarrow\left(A, B_{k}, N^{\prime}\right)$ if $C::=f\left(B_{1}, \ldots, B_{i-1},[\cdot], B_{i+1}, \ldots B_{n}\right)$, and $w_{N} \perp m p\left(w_{C}\right)$, i.e. $k \neq i$, where $N^{\prime}$ is a nonterminal in $G_{s}^{\prime}$ with $w_{N}=$ $k w_{N^{\prime}}$.
4. $(A, C, N) \rightarrow\left(A, C_{1}, N\right)$ if $C::=C_{1} C_{2}, w_{N} \perp m p\left(w_{C_{1}}\right)$.
5. $(A, C, N) \rightarrow\left(A, C_{2}, N^{\prime}\right)$ if $C::=C_{1} C_{2}$, and $m p\left(w_{C_{1}}\right)$ is a prefix of $w_{N}$, where $N^{\prime}=\varepsilon$ if $m p\left(w_{C_{1}}\right)=w_{N}$, or $N^{\prime}$ is a nonterminal in $G_{s}^{\prime}$ with $w_{N}=m p\left(w_{C_{1}}\right) w_{N^{\prime}}$.
6. $(A, C, N) \rightarrow\left\{\left(A, C_{1}, N\right),\left(C_{2}, A, N^{\prime}\right)\right\}$ if $C::=C_{1} C_{2}$, and $w_{N}$ is a proper prefix of $m p\left(w_{C_{1}}\right)$, where $w_{N} w_{N^{\prime}}=m p\left(w_{C_{1}}\right)$ and $N^{\prime}$ is a nonterminal in $G_{s}^{\prime}$.

- (C,C)-case. An illustration of the cases 4 to 6

1. $\left(C_{1}, C_{2}, \varepsilon\right) \rightarrow\left\{\left(A_{1}, C_{2}, N_{1}\right), \ldots,\left(A_{i-1}, C_{2}, N_{i-1}\right),\left(A_{i+1}, C_{2}, N_{i+1}\right)\right.$, $\left.\ldots,\left(A_{n}, C_{2}, N_{n}\right)\right\}$ if $C_{1}::=f\left(A_{1}, \ldots, A_{i-1},[\cdot], A_{i+1}, \ldots, A_{n}\right)$, where $G_{s}^{\prime}$ contains the nonterminals $N_{1}, \ldots, N_{n}$ with rules $N_{i}::=i$ for $i=1, \ldots, n$.
2. $\left(C_{1}, C_{2}, \varepsilon\right) \rightarrow\left\{\left(C_{3}, C_{2}, \varepsilon\right),\left(C_{4}, C_{2}, N\right)\right\}$ if $C_{1}::=C_{3} C_{4}$, where $N$ is the nonterminal in $G_{s}$ with $w_{N}=m p\left(w_{C_{3}}\right)$.
3. $\left(C_{1}, C_{2}, N\right) \rightarrow\left(C_{1}, A_{k}, N^{\prime}\right)$ if $C_{2}::=f\left(A_{1}, \ldots, A_{i-1},[\cdot], A_{i+1}, \ldots A_{n}\right)$ and $w_{N} \perp m p\left(w_{C_{2}}\right)$, i.e., $k \neq i$, where $N^{\prime}$ is a nonterminal in $G_{s}^{\prime}$ with $w_{N}=k w_{N^{\prime}}$.
4. $\left(C_{1}, C_{2}, N\right) \rightarrow\left(C_{1}, C_{3}, N\right)$ if $C_{2}::=C_{3} C_{4}, w_{N} \perp m p\left(w_{C_{3}}\right)$.
5. $\left(C_{1}, C_{2}, N\right) \rightarrow\left(C_{1}, C_{4}, N^{\prime}\right)$ if $C_{2}::=C_{3} C_{4}$, and $m p\left(w_{C_{3}}\right)$ is a prefix of $w_{N}$, where $N^{\prime}=\varepsilon$ if $m p\left(w_{C_{3}}\right)=w_{N}$, or $N^{\prime}$ is a nonterminal in $G_{s}^{\prime}$ with $w_{N}=m p\left(w_{C_{3}}\right) w_{N^{\prime}}$.
6. $\left(C_{1}, C_{2}, N\right) \rightarrow\left\{\left(C_{1}, C_{3}, N\right),\left(C_{4}, C_{1}, N^{\prime}\right)\right\}$ if $C_{2}::=C_{3} C_{4}$, and $w_{N}$ is a proper prefix of $m p\left(w_{C_{3}}\right)$, where $w_{N} w_{N^{\prime}}=m p\left(w_{C_{3}}\right)$ and $N^{\prime}$ is a nonterminal in $G_{s}^{\prime}$.

- (C,T)-case. An illustration of the transformations of $\varepsilon$-triples in cases 2 to 4 is:

An illustration of the transformation in cases 6 to 8 is:

1. $(C, A, \varepsilon) \rightarrow\left\{\left(A_{1}, C, N_{1}\right), \ldots,\left(A_{n}, C, N_{n}\right)\right\}$ if $A::=f\left(A_{1}, \ldots, A_{n}\right)$, where $G_{s}^{\prime}$ contains the nonterminals $N_{1}, \ldots, N_{n}$ with rules $N_{i}::=i$ for $i=$ $1, \ldots, n$.
2. $\left(C_{1}, A, \varepsilon\right) \rightarrow\left\{\left(C_{1}, C_{2}, \varepsilon\right),\left(A^{\prime}, C_{1}, N\right)\right\}$ if $A::=C_{2}\left[A^{\prime}\right]$ and $m p\left(w_{C_{1}}\right) \perp$ $m p\left(w_{C_{2}}\right)$ where $w_{N}=m p\left(w_{C_{2}}\right)$.
3. $\left(C_{1}, A, \varepsilon\right) \rightarrow\left(C_{1}, C_{2}, \varepsilon\right)$ if $A::=C_{2}\left[A^{\prime}\right]$ and $m p\left(w_{C_{1}}\right)$ is a prefix of $m p\left(w_{C_{2}}\right)$.
4. $\left(C_{1}, A, \varepsilon\right) \rightarrow\left\{\left(C_{1}, C_{2}, \varepsilon\right),\left(A^{\prime}, C_{1}, N\right)\right\}$ if $A::=C_{2}\left[A^{\prime}\right]$ and $m p\left(w_{C_{2}}\right)$ is a proper prefix of $m p\left(w_{C_{1}}\right)$, where $N$ is the nonterminal in $G_{s}$ with $w_{N}=m p\left(w_{C_{2}}\right)$.
5. $(C, A, N) \rightarrow\left(C, A_{i}, N^{\prime}\right)$ if $A::=f\left(A_{1}, \ldots, A_{n}\right)$, where either $N^{\prime}=\varepsilon$ if $w_{N}=i$, or $N^{\prime}$ is a nonterminal in $G_{s}^{\prime}$ with $w_{N}=i w_{N^{\prime}}$.
6. $\left(C_{1}, A, N\right) \rightarrow\left(C_{1}, C_{2}, N\right)$ if $A::=C_{2}\left[A^{\prime}\right]$ and $w_{N} \perp m p\left(w_{C_{2}}\right)$.
7. $\left(C_{1}, A, N\right) \rightarrow\left\{\left(C_{1}, A^{\prime}, N^{\prime}\right)\right\}$ if $A::=C_{2}\left[A^{\prime}\right]$ and $m p\left(w_{C_{2}}\right)$ is a prefix of $w_{N}$, where either $N^{\prime}=\varepsilon$ if $w_{N}=m p\left(w_{C_{2}}\right)$, or $N^{\prime}$ is a nonterminal in $G_{s}^{\prime}$ with $w_{N}=m p\left(w_{C_{2}}\right) w_{N^{\prime}}$
8. $\left(C_{1}, A, N\right) \rightarrow\left\{\left(C_{1}, C_{2}, N\right),\left(A^{\prime}, C_{1}, N^{\prime}\right)\right\}$ if $A::=C_{2}\left[A^{\prime}\right]$ and $w_{N}$ is a proper prefix of $m p\left(w_{C_{2}}\right)$, where $N^{\prime}$ is a nonterminal in $G_{s}^{\prime}$ with $w_{N} w_{N^{\prime}}=m p\left(w_{C_{2}}\right)$.

### 7.3 Failure Rules for Compaction

We will use periodicities of contexts for compaction of the set $S_{o t}$.
There are three failure rules, which we apply with high priority in the algorithm WOPS.
(CompFailAC) Given two different overlay triples $\left(A, C, N_{1}\right),\left(A, C, N_{2}\right)$ where $A$ is a tree nonterminal and $C$ is a context nonterminal. Let $p_{i}$ be such that $m p\left(w_{C}\right)=w_{N_{i}} p_{i}$ for $i=1,2$. Fail, if $p_{1} \perp p_{2}$.
(CompFailCCorth) Given two different orthogonal overlay triples $\left(D, C, N_{1}\right),\left(D, C, N_{2}\right)$, where $D, C$ are context nonterminals, $\left|w_{N_{1}}\right|<\left|w_{N_{2}}\right|$, $m p\left(w_{C}\right) \perp w_{N_{1}} m p\left(w_{D}\right)$ and $m p\left(w_{C}\right) \perp w_{N_{2}} m p\left(w_{D}\right)$.
For $i=1,2$, let $p_{i}$ be the maximal position, such that $w_{N_{i}} p_{i}$ is a prefix of $m p\left(w_{C}\right)$. For $i=1,2$, let $q_{i}$ be the position, such that $w_{N_{i}} p_{i} q_{i}=m p\left(w_{C}\right)$.
Fail, if one of the following conditions hold:

$$
\begin{aligned}
& -p_{1} \neq p_{2} . \\
& -q_{1} \perp q_{2}
\end{aligned}
$$

Correctness of the failure rule (CompFailCCorth) is proved in Lemma 9.7. Hence for orthogonal overlay triples $(D, C, N)$ the part of the main path of $D$ that is parallel to the main path of $C$ is independent of $N$, and we can define the common path length ( $p_{1}$ above) for orthogonal overlay triples ( $\left.D, C, \cdot\right)$ as $c p(D, C)$.

### 7.4 Compaction Rules

For the application of the compaction rules we assume that no failure rule applies. There are three different variants of the compaction rule for $S_{o t}$ :
(CompactAC) Given three different tree overlay triples $\left(A, C, N_{1}\right),\left(A, C, N_{2}\right),\left(A, C, N_{3}\right) \quad$ where $\quad A \quad$ is a tree nonterminal and $C$ is a context nonterminal, and $\left|w_{N_{1}}\right|<\left|w_{N_{2}}\right|<\left|w_{N_{3}}\right|$. If $\left(\left|w_{N_{2}}\right|-\left|w_{N_{1}}\right|\right)+\left(\left|w_{N_{3}}\right|-\left|w_{N_{1}}\right|\right) \leq\left|m p\left(w_{C}\right)\right|-\left|w_{N_{1}}\right|$, then replace the three triples by two triples $\left(A, C, N_{1}\right),\left(A, C, N_{4}\right)$, where $N_{4}$ is a nonterminal in $G_{s}^{\prime}$ and $w_{N_{4}}$ is a prefix of $m p\left(w_{C}\right)$ such that $\left|w_{N_{4}}\right|=\left|w_{N_{1}}\right|+\operatorname{gcd}\left(\left(\left|w_{N_{2}}\right|-\left|w_{N_{1}}\right|\right),\left(\left|w_{N_{3}}\right|-\mid w_{N_{1}}\right)\right)$.
(CompactCCpar) Given three different parallel overlay triples $\left(D, C, N_{1}\right),\left(D, C, N_{2}\right),\left(D, C, N_{3}\right)$ where $D, C$ are context nonterminals, $m p\left(w_{C}\right)\left|\mid w_{N_{i}} m p\left(w_{D}\right)\right.$ for $i=1,2,3$, and $| w_{N_{1}}\left|<\left|w_{N_{2}}\right|<\left|w_{N_{3}}\right|\right.$. If $\left(\left|w_{N_{2}}\right|-\left|w_{N_{1}}\right|\right)+\left(\left|w_{N_{3}}\right|-\left|w_{N_{1}}\right|\right) \leq\left|m p\left(w_{C}\right)\right|-\left|w_{N_{1}}\right|$, then replace the three triples by two triples $\left(D, C, N_{1}\right),\left(D, C, N_{4}\right)$, where $N_{4}$ is a nonterminal in $G_{s}^{\prime}$ and $w_{N_{4}}$ is a prefix of $m p\left(w_{C}\right)$ such that $\left|w_{N_{4}}\right|=\left|w_{N_{1}}\right|+\operatorname{gcd}\left(\left(\left|w_{N_{2}}\right|-\left|w_{N_{1}}\right|\right),\left(\left|w_{N_{3}}\right|-\mid w_{N_{1}}\right)\right)$.
(CompactCCorth) Given four different orthogonal overlay triples $\left(D, C, N_{0}\right),\left(D, C, N_{1}\right),\left(D, C, N_{2}\right),\left(D, C, N_{3}\right) \quad$ where $\quad D, C \quad$ are context nonterminals, $m p\left(w_{C}\right) \perp w_{N_{i}} m p\left(w_{D}\right)$ for $i=0, \ldots, 3$, and $\left|w_{N_{0}}\right|<\left|w_{N_{1}}\right|<\left|w_{N_{2}}\right|<\left|w_{N_{3}}\right|$. Let $p:=|c p(D, C)|$ and let $d:=\left|m p\left(w_{C}\right)\right|-p-1$. If $\left(\left|w_{N_{1}}\right|-\left|w_{N_{0}}\right|\right)+\left(\left|w_{N_{2}}\right|-\left|w_{N_{0}}\right|\right) \leq\left(d-\left|w_{N_{0}}\right|\right)$, and $\left(\left|w_{N_{2}}\right|-\left|w_{N_{1}}\right|\right)+\left(\left|w_{N_{3}}\right|-\left|w_{N_{1}}\right|\right) \leq\left(d-\left|w_{N_{1}}\right|\right)$, then replace the two triples $\left(D, C, N_{2}\right),\left(D, C, N_{3}\right)$ by the triple $\left(D, C, N_{4}\right)$, where $N_{4}$ is a nonterminal in $G_{s}^{\prime}$ and $w_{N_{4}}$ is a prefix of $m p\left(w_{C}\right)$ such that $\left|w_{N_{4}}\right|=\left|w_{N_{1}}\right|+\operatorname{gcd}\left(\left(\left|w_{N_{2}}\right|-\left|w_{N_{1}}\right|\right),\left(\left|w_{N_{3}}\right|-\mid w_{N_{1}}\right)\right)$.

Note that the difference between the three rules is in the kind of the nonterminal $D$, the relative position of the different $D$ 's in case $D$ is a context nonterminal, and in the extra required triple ( $D, C, N_{0}$ ) in rule (CompactCCorth).

Note also that it is possible for two context nonterminals $C, D$ that there are orthogonal overlay triples as well as parallel overlay triples in $S_{o t}$.

## 8 Properties of the Transformation Rules

Lemma 8.1. The simplification and transformation rules are sound and complete, i.e., if the state $S$ is transformed into $S^{\prime}$, then

1. all the triples in $S$ are well-formed iff all triples are well-formed in $S^{\prime}$; and
2. all triples in $S$ are valid iff they are valid in $S^{\prime}$.

Proof. This follows by a straightforward, but tedious inspection of the rules.

Now we count the the number of different triples during the transformation and the number of necessary transformations. The critical transformation rules are TT,5, TC,6, CC,6, and CT, 8, since these rules increase the number of triples and can be applied more than once.
 following possibilities to generate new kinds of triples:

1. In case TT.5. with transformation $(A, B, N) \rightarrow\left\{(A, C, N),\left(B^{\prime}, A, N^{\prime}\right)\right\}$, the triple $(A, C, N)$ is an overlay triple.
2. In case TC. 6. with transformation $(A, C, N) \rightarrow\left\{\left(A, C_{1}, N\right),\left(C_{2}, A, N^{\prime}\right)\right\}$, the triple $\left(A, C_{1}, N\right)$ is an overlay triple.
3. In case CC.6, with transformation $\left(C_{1}, C_{2}, N\right) \rightarrow$ $\left\{\left(C_{1}, C_{3}, N\right),\left(C_{4}, C_{1}, N^{\prime}\right)\right\}$, either $\left(C_{1}, C_{3}, N\right)$ is an overlay triple, or $\left(C_{4}, C_{1}, N^{\prime}\right)$ is immediately removed by simplification.
4. In case $C T$ 8, with transformation $\left(C_{1}, A, N\right) \rightarrow\left\{\left(C_{1}, C_{2}, N\right),\left(A^{\prime}, C_{1}, N^{\prime}\right)\right\}$, either the triple $\left(C_{1}, C_{2}, N\right)$ is an overlay triple, or the triple $\left(A^{\prime}, C_{1}, N^{\prime}\right)$ is removed immediately by simplification.

Proof. 1. The following picture illustrates the TT-case TT. 5 and the TC-case TC 6

In the TT 5 it is obvious that $(A, C, N)$ is an overlay triple, since $A$ is a tree nonterminal and $w_{N} \| m p\left(w_{C}\right)$. In TC. 6 case it is obvious that $\left(A, C_{1}, N\right)$ is an overlay triple, since $A$ is a tree nonterminal and $w_{N} \| m p\left(w_{C_{1}}\right)$.
2. The following picture illustrates the three CC-cases corresponding to CC.6.

In the first and second case, $\left(C_{1}, C_{3}, N\right)$ is an overlay triple, since $w_{N} \|$ $m p\left(w_{C_{3}}\right)$ and $C_{1}$ is a context nonterminal such that $w_{N} m p\left(w_{C_{1}}\right)$ is not a prefix of $m p\left(w_{C_{3}}\right)$. In the third case, $\left(C_{1}, C_{3}, N\right)$ is an inclusion triple, and $\left(C_{4}, C_{1}, N^{\prime}\right)$ will be removed by simplification, since $m p\left(w_{C_{1}}\right)$ is a prefix of $w_{N^{\prime}}$.
3. The following picture illustrates the three CT-cases corresponding to CT, 8

In the first and second case, $\left(C_{1}, C_{2}, N\right)$ is an overlay triple, since $w_{N} \|$ $m p\left(w_{C_{2}}\right)$ and $C_{1}$ is a context nonterminal such that $w_{N} m p\left(w_{C_{1}}\right)$ is not a prefix of $m p\left(w_{C_{2}}\right)$. In the third case, $\left(C_{1}, C_{2}, N\right)$ is an inclusion triple, and ( $A^{\prime}, C_{1}, N^{\prime}$ ) will be removed by simplification, since $m p\left(w_{C_{1}}\right)$ is a prefix of $w_{N^{\prime}}$.

Lemma 8.3. All strictly descending chains w.r.t. the strict ordering on triples have length at most $2 *|G|$.

Proof. Obvious.
Lemma 8.4. For every transformation of a triple $\left(D_{1}, D_{2}, N\right)$, the resulting triples are strictly smaller w.r.t. the ordering on triples defined in 6.4.

Proof. Follows from an inspection of the rules.
Proposition 8.5. For every transformation of a triple, the resulting triples are strictly smaller.

For every transformation of a non- $\varepsilon$-triple, after applying simplification to the resulting triples, at most one triple of the result is not an overlay triple.

Lemma 8.6. Let $G$ be the initial $S T G$.
The number of $\varepsilon$-triples is at most $|G|^{2}$.
The number of non- $\varepsilon$-triples coming from a single transformation from $\varepsilon$-triples is $\leq\left(|G|^{2}\right) *$ maxarity.

Proof. The upper bound is obvious. The treatment of $\varepsilon$-triples in the transformations shows that at most maxarity triples may arise from a single $\varepsilon$-triple.

Lemma 8.7. Let $G$ be the initial $S T G$. During every run of the algorithm WOPS, the number of triples in $S_{n o t}$ is bounded by maxarity.

Proof. Only $\varepsilon$-triples may add maxarity triples to $S_{\text {not }}$. The priority of choosing triples for further transformations and Proposition 8.5 show that the focussed triple may result in at most one further triple from $S_{n o t}$, and perhaps triples in the other sets.

Since we already have bounded the sets of $\varepsilon$-triples and the set $S_{n o t}$, it remains to treat the set $S_{o t}$.

## 9 Correctness of the Compaction and Failure Rules

For the proofs of correctness we assume that the simplifications are exhaustively applied.

### 9.1 The tree-context-case

The following lemma is also proved in SSS98.
Lemma 9.1. Let $W$ be a nontrivial context, and let $p$ be a position, such that $W$ overlaps itself at position $p$, i.e., for every position $q$, such that $p q \in \operatorname{Pos}(W)$, we have head $\left(\left.W\right|_{p q}\right)=$ head $\left(\left.W\right|_{q}\right)$. Then the following holds:

1. $p \| m p(W)$, i.e. the overlapping start on the main path.
2. $m p(W) \| p \cdot m p(W)$, i.e., the paths of both occurrences of $W$ are on the same path.

Proof. The first claim is clear, since $p \perp m p(W)$ would imply that $W$ contains $W$ properly.

In the second case, assume that $m p(W) \perp p \cdot m p(W)$. Then $p \neq \varepsilon$. Let $p^{\prime}$ be the maximal prefix of $m p(W)$, such that $p p^{\prime} \| m p(W)$. Then $\left.W\right|_{p p^{\prime}}=$ $f\left(t_{1}, \ldots, t_{i-1}, \cdot, t_{i+1}, \ldots, t_{n}\right)$, and there is $k \neq i$, such that $p^{\prime} k$ is a prefix of $m p(W)$. But then $t_{k}$ contains itself properly, a contradiction.

Lemma 9.2. The failure rule (CompFailAC) is correct.
Proof. Assume we have two valid overlay triples $\left(A, C, N_{1}\right),\left(A, C, N_{2}\right)$, where $A$ is a tree nonterminal and $C$ is a context nonterminal. Since $N_{1} \| N_{2}$, we can assume w.l.o.g. that $\left|w_{N_{1}}\right|<\left|w_{N_{2}}\right|$.
Let $p_{i}$ be such that $m p\left(w_{C}\right)=w_{N_{i}} p_{i}$ for $i=1,2$. Let $W$ be the context derived from $w_{A}$ by plugging in the hole at position $p_{1}$. Since $\left(A, C, N_{1}\right)$ is a overlay triple, we also have $W=\left.w_{C}\right|_{w_{N_{1}}}$. The valid overlay triple $\left(A, C, N_{2}\right)$ with $\left|w_{N_{1}}\right|<\left|w_{N_{2}}\right|$ implies that there is another overlay of $W$ in $w_{C}$ starting at position $w_{N_{2}}$. Now Lemma 9.1 shows that $p_{1} \| p_{2}$.

Lemma 9.3. The compaction rule (CompactAC) is sound and complete.
Proof. Assume we have three valid overlay triples $\left(A, C, N_{1}\right),\left(A, C, N_{2}\right),\left(A, C, N_{3}\right)$, where $A$ is a tree nonterminal and $C$ is a context nonterminal, the failure rules do not apply, and $\left|w_{N_{1}}\right|<\left|w_{N_{2}}\right|<\left|w_{N_{3}}\right|$. Let $p_{i}$ be such that $m p\left(w_{C}\right)=w_{N_{i}} p_{i}$ for $i=1,2,3$. Since the failure rules do not apply, $p_{3}$ is a prefix of $p_{2}$ and $p_{2}$ is a prefix of $p_{1}$. Thus we have an overlapping situation for contexts (similar to words). Let $W:=\left.w_{C}\right|_{w_{N_{1}}}$. The two triples $\left(A, C, N_{1}\right),\left(A, C, N_{2}\right)$ show that $W$ has a period $\left|w_{N_{2}}\right|-\left|w_{N_{1}}\right|$, the two triples $\left(A, C, N_{1}\right),\left(A, C, N_{3}\right)$ show that $W$ has a period $\left|w_{N_{3}}\right|-\left|w_{N_{1}}\right|$, and the context $W$ seen as word, has length $\left|m p\left(w_{C}\right)\right|-\left|w_{N_{1}}\right|$. Hence we can use Lemma 2.1, and obtain that if $\left(\left|w_{N_{2}}\right|-\left|w_{N_{1}}\right|\right)+\left(\left|w_{N_{3}}\right|-\left|w_{N_{1}}\right|\right) \leq\left|m p\left(w_{C}\right)\right|-\left|w_{N_{1}}\right|$, the context $W$ also has period $\operatorname{gcd}\left(\left(\left|w_{N_{2}}\right|-\left|w_{N_{1}}\right|\right),\left(\left|w_{N_{3}}\right|-\mid w_{N_{1}}\right)\right)$. Thus the generation of $N_{4}$ and the replacement of $\left(A, C, N_{2}\right),\left(A, C, N_{3}\right)$ with $\left(A, C, N_{4}\right)$ keeps exactly the information.

### 9.2 The parallel context-context-case

Similar to the tree-context-case.

Lemma 9.4. The compaction rule (CompactCCpar) is sound and complete.
Proof. The proof is the same as the proof of Lemma 9.3 by replacing $W$ with $W^{\prime}$, where $W^{\prime}=\left.w_{D}\right|_{p}$, and $w_{N_{1}} p=m p\left(w_{C}\right)$.

### 9.3 The orthogonal context-context-case

We need a helpful lemma on overlaps of a word with itself, where one position is undefined, before we can treat the orthogonal CC-case. It can be seen as a generalization of a periodicity lemma for a word overlapping with itself to a periodicity lemma of a word $w$ overlapping with its single-point mutants where the mutations are at a fixed position in $w$.

We denote the letter at position $i$ in a word with $w[i]$, where we assume that the first letter is $w[1]$. With $(v, w, k)$ we denote an overlap of the words $v, w$ where $w$ starts with the $(k+1)^{\text {st }}$ letter of $v$. The notation $(v, w, k)$ means that for all $i=k+1, \ldots, \min (|v|,|w|+k)$, we have $v[i]=w[i-k]$. The triple $(v, v, k)$ implies that the word $v$ has period $k$.

Lemma 9.5. Let $w_{1}, w_{2}$ be words, $x_{1}, x_{2}, x_{3}$ be letters, and $v_{i}=w_{1} x_{i} w_{2}$ for $i=1,2,3$. Let there be two overlaps $\left(v_{1}, v_{2}, m\right),\left(v_{1}, v_{3}, n\right)$ for $1 \leq m<n$. Then the following holds:

If $m+n \leq\left|w_{2}\right|$, then $v_{2}$ has period $\operatorname{gcd}(m, n), x_{2}=x_{3}=w_{2}[\operatorname{gcd}(m, n)]$, and $v_{2}=v_{3}$.

Proof.

There are also overlaps $\left(w_{2}, w_{2}, m\right),\left(w_{2}, w_{2}, n\right)$, which means $w_{2}$ has periods $m, n$. Hence by the condition $m+n \leq\left|w_{2}\right|$ and Lemma 2.1, $r:=\operatorname{gcd}(m, n) \leq$ $\min (m, n)$ is also a period of $w_{2}$. The overlap shows (see e.g. the illustration), that $x_{2}=w_{2}[m]$. Comparing $v_{1}, v_{2}$ and from the period $r$, we obtain $x_{2}=w_{2}[m]=$ $w_{2}[m+h * r]$ for integers $h$, as long as $1 \leq m+h * r \leq\left|w_{2}\right|$, hence $x_{2}=w_{2}[r]$. The same holds for the comparison of $v_{1}, v_{3}$, which implies $x_{2}=x_{3}=w_{2}[r]$, and also $v_{2}=v_{3}$. There is an overlap $\left(v_{3}, w_{2}, n\right)$, and the overlap is synchronized, since $m+n \leq\left|w_{2}\right|$ and the $w_{2}$-parts of $v_{1}, v_{3}$ have an overlap larger than $r$. Let $w_{3}$ be the maximal suffix of length $\leq n$ of $w_{1}$. Then the overlap of $v_{1}$ with $v_{3}$ shows that $w_{3} x_{3} w_{2}$ is a suffix of $v_{3}$ and has period $r$. If $\left|w_{1}\right|<m$, then $w_{3} x_{3} w_{2}=v_{2}=v_{3}$, and $v_{2}, v_{3}$ have period $r$. If $\left|w_{1}\right| \geq m$, then $v_{2}$ and $x_{1}$ in $v_{1}$ have a common position in the overlap of $v_{1}, v_{2}$. Due to the period $r$, we obtain that $x_{1}=x_{2}$.

Example 9.6. There are examples with $x_{1} \neq x_{2}$ in the first case of Lemma 9.5, e.g.: $w_{1}=\mathrm{a}, w_{2}=$ ababab, $x_{1}=\mathrm{c}, x_{2}=x_{3}=\mathrm{b}, m=2, n=4$. We use $x=x, y=x_{2}, z=x_{3}$. The values of $y, z$ are fixed to be $b$, but the value of $x$ is not restricted.

```
v3 . . . . a z a b a b a b a b a b
v
v
```

Lemma 9.7. Let there be two valid orthogonal overlay triples $\left(D, C, N_{1}\right),\left(D, C, N_{2}\right)$, where $C, D$ are context nonterminals, such that $w_{N_{1}} m p\left(w_{D}\right) \perp m p\left(w_{C}\right)$ and $w_{N_{2}} m p\left(w_{D}\right) \perp m p\left(w_{C}\right)$. For $i=1,2$ let $p_{i}$ be the maximal paths such that $p_{i}$ is a prefix of $w_{D}$ and $w_{N_{i}} p_{i} \| m p\left(w_{C}\right)$, and let $q_{i}$ be such that $w_{N_{1}} p_{i} q_{i}=m p\left(w_{C}\right)$. Then the following holds:

$$
\begin{aligned}
& -p_{1}=p_{2} \\
& -q_{1} \| q_{2}
\end{aligned}
$$

A picture of a possible situation is:

Proof. W.l.o.g. we assume that $\left|w_{N_{1}}\right|<\left|w_{N_{2}}\right|$.
First suppose that $p_{1} \neq p_{2}$. From the assumptions it is clear that $p_{1} \| p_{2}$. Let $q$ be such that $w_{N_{1}} p_{1} q=w_{N_{2}} p_{1}$. Looking at the picture, we have to distinguish the cases that $p_{1}$ is a prefix of $p_{2}$, and the case that $p_{2}$ is a prefix of $p_{1}$. It is easy to see that in each of the cases we can construct an arbitrarily long path in $D$ of the form $p_{1} q^{+}$, which contradicts the finiteness of contexts. This proves the first part.

Now assume that $q_{1} \perp q_{2}$. Let $\left.w_{D}\right|_{p_{1}}=f\left(t_{1}, \ldots, t_{i-1}, W^{\prime}, t_{i+1}, \ldots, t_{n}\right)$ and let $k$ be the first letter of $w_{q_{1}}$. It is clear that $k \neq i$. Let $D^{\prime}$ be generated from $\left.D\right|_{p_{1} k}$ by plugging in a hole at position $q_{1}$. Now we can apply Lemma 9.1 to the overlap of $D^{\prime}$ with itself and obtain that $q_{1} \| q_{2}$.

Example 9.8. We give an example that the orthogonal case treated in Lemma 9.7 may indeed be possible.

$$
\begin{array}{ll}
C \quad:=g(f(g(f([\cdot], a)), a)) & p_{1}:=\varepsilon \\
D \quad:=f(g(f(a, a)),[\cdot]) & p_{2}:=\varepsilon \\
w_{N_{1}}:=1 & q_{1}:=1.1 .1 \\
w_{N_{2}}:=1.1 .1 & q_{2}:=1
\end{array}
$$

A picture of the overlapping situation is:

Lemma 9.9. The failure rule (CompFailCCorth) is correct.
Proof. Follows from Lemma 9.7
Lemma 9.10. The compaction rule (CompactCCorth) is sound and complete.
Proof. Recall the notation of the rule (CompactCCorth). For $i=0, \ldots, 3$, let $k_{i}$ be a letter and $r_{i}$ be a postion string, such that $\mp(C)=w_{N_{i}} \cdot c p(D, C) \cdot k_{i} \cdot r_{i}$, where $k_{i}$ is a letter. For $i=0,1,2,3$, let $u_{1, i}, x_{i}, u_{2, i}$ be contexts, such that $u_{1, i} x_{i} u_{2, i}=\left(w_{C}\right)_{\mid N_{i}}$, and $m p\left(u_{1, i}\right)=c p(D, C)$. Lemma 9.7 can be applied to show that $u_{1,0}=u_{1,1}=u_{1,2}=u_{1,3}$ and that $u_{2,3}$ is a prefix of $u_{2,2}, u_{2,2}$ is a prefix of $u_{2,1}$, and $u_{2,1}$ is a prefix of $u_{2,0}$. Now we can apply Lemma 9.5 to the words $v_{0}:=u_{1,0} x_{0} u_{2,0}$ and $v_{1}:=u_{1,0} x_{1} u_{2,0}$ and $v_{2}:=u_{1,0} x_{2} u_{2,0}$, which due to the first length condition in the rule implies that $x_{1}=x_{2}$ and $v_{1}=v_{2}$. A further application of Lemma 9.5 to the words $v_{1}^{\prime}:=u_{1,0} x_{1} u_{2,1}$ and $v_{2}^{\prime}:=u_{1,0} x_{2} u_{2,1}$ and $v_{2}:=u_{1,0} x_{3} u_{2,1}$ shows that $x_{2}=x_{3}$ and $v_{2}^{\prime}=v_{3}^{\prime}$ due to the second length condition in the rule. This implies that $v_{1}^{\prime}=v_{2}^{\prime}=v_{3}^{\prime}$, and we can use the periodicity Lemma 9.5 and Lemma 9.7 can be applied. The length condition on $N_{0}, N_{1}, N_{2}$ in rule (CompactCCorth) implies by Lemma 9.5 (by appropriately prolonging that $v_{i}^{\prime}$ is a suffix of $w_{2,1}$ and the length condition on $N_{1}, N_{2}, N_{3}$ in rule (CompactCCorth) implies that $w_{2,3}$ is a suffix of $w_{2,2}$. Thus we can use periods of words as in the parallel case (see the proof of Lemma 9.3), and no information is lost by replacing the two triples by the $N_{4}$-triple.

### 9.4 Restricting the Number of Overlay Triples

We generalize Plandowski's argument to show that there will be at most $O\left(n^{3}\right)$ overlay triples for $(A, C, N)$.

Lemma 9.11. If failure and compaction rules have been exhaustively applied, then the cardinality of $S_{o t}$ is bounded by $(5 n+4) * n^{2}$, where $n=|G|$, i.e. by $O\left(n^{3}\right)$.

Proof. The proof follows Plandowski's reasoning Pla94:
We fix $D, C$ and assume that there are overlay triples in $S_{o t}$. There may be parallel overlay triples and orthogonal overlay triples in $S_{o t}$. First we consider sequences of triples that consist only of parallel overlay triples. Let $\left(D, C, N_{1}\right),\left(D, C, N_{2}\right),\left(D, C, N_{3}\right), \ldots,\left(D, C, N_{k}\right)$ be triples in $S_{o t}$, where we assume that $\left|w_{N_{1}}\right|<\left|w_{N_{2}}\right|<\ldots<\left|w_{N_{k}}\right|$. Let $j$ be an index in the sequence. To simplify the reasoning, let $d_{i}:=\left|w_{N_{i}}\right|$ for all appropriate $i$. Since compaction is not applicable, the inequation $\left(d_{j+2}-d_{j}\right)+\left(d_{j+1}-d_{j}\right)>\left|m p\left(w_{C}\right)\right|-d_{j}$ holds. Since $d_{j+2}>d_{j+1}$, this implies $2 * d_{j+2}-d_{j}>\left|m p\left(w_{C}\right)\right|$. This gives $\left|m p\left(w_{C}\right)\right|+$ $2 * d_{j+2}-d_{j}>2 *\left|m p\left(w_{C}\right)\right|$ which implies $\left|m p\left(w_{C}\right)\right|-d_{j}>2\left(\left|m p\left(w_{C}\right)\right|-d_{j+2}\right)$ and $0.5\left(\left|m p\left(w_{C}\right)\right|-d_{j}\right)>\left|m p\left(w_{C}\right)\right|-d_{j+2}$. Since $\left|m p\left(w_{C}\right)\right| \leq 2^{|G|}$, and the numbers on the left and right of the inequation are positive, the sequence of numbers $\left|m p\left(w_{C}\right)\right|-d_{1},\left|m p\left(w_{C}\right)\right|-d_{2}, \ldots,\left|m p\left(w_{C}\right)\right|-d_{k}$ has at most $2|G|+1$ elements.

Now we can also treat sequences of purely orthogonal overlay triples. The difference is that given a sequence $\left(D, C, N_{1}\right),\left(D, C, N_{2}\right),\left(D, C, N_{3}\right), \ldots$, the same estimation as above shows that for every $j$, provided the indices $j+1, j+2, j+3$ are valid, the inequation $0.5\left(d-d_{j}\right)>d-d_{j+2}$ or $0.5\left(d-d_{j+1}\right)>d-d_{j+3}$ holds, where $d:=\left|m p\left(w_{C}\right)\right|-|c p(D, C)|-1$. It is clear that $d-d_{k} \geq 0$ for all $k$ must hold. The estimation shows that the possible interval length $\left(d-d_{k}\right)$ is divided at least by two going from $j$ to $j+3$, hence there are at most $3|G|+3$ elements in a sequence $d_{i}$. Since per pair $D, C$ there may be 2 kinds of sequences, the overall maximal number is $(5 n+4) * n^{2}$, where $n=|G|$.

### 9.5 Complexity of WOPS

Lemma 9.12. The size of the position grammar in WOPS is bounded by $|G|+$ $P * \operatorname{depth}(G)$, where $P$ is the number of transformation and compaction steps of WOPS .

Proof. The size-increase of $G_{s}$ in every step is always the addition of a prefix or suffix of a position of a certain length. This may happen in the transformation rules or in the compaction rules. By Lemma 3.6 the size increase in every step is at most by adding $\operatorname{depth}(G)$.

Now we can prove the main theorem:
Theorem 9.13. The algorithm WOPS requires at most polynomially many steps in the size $|G|$ of the input STG $G$.

Proof. For the complexity of the algorithm we have to take into account the priority of the rule applications. The sequence of states can be divided into intermediate states (we call them pot-states) where only $S_{\varepsilon, \text { closed }}$ and $S_{o t}$ are nonempty and failure and compaction rules are applied exhaustively. The transformation sequence between two such pot-states is called pot-meta-transformation. We have to argue that only polynomially many pot-states are possible.

The first argument is that $S_{o t}$ itself is polynomially bounded by $O\left(|G|^{3}\right)$, which is proved in Lemma 9.11. Let $(D, C, N)$ be a maximal triple in $S_{o t}$. Then there are at most $5|G|+4$ triples of the form $\left(D, C, N^{\prime}\right)$ in $S_{o t}$. Thus after at most $5|G|+4$ pot-meta-transformations of $S_{o t}$, a pot-state is reached, such that it is no longer possible to have a triple $\left(D, C, N^{\prime}\right)$ in any active set in any successor state. This can happen at most $|G|^{2}$ times. Thus the number of pot-meta-transformations is $O\left(|G|^{3}\right)$, i.e., polynomial.

The number of transformations and compactions in a single pot-metatransformation can be bounded above as follows. There may be at most $O\left(|G|^{2}\right)$ triples in $S_{\varepsilon, \text { open }}$, and the immediate successor triples are at most $O\left(|G|^{2}\right)$ (see Lemma 8.6). Every triple may give rise to a transformation of length at most $O\left(|G|^{2}\right)$. Every step may be accompanied by polynomially many compaction rule applications. Hence the number of transformations and compaction rule applications in a pot-meta-transformation is polynomially bounded. Lemma 9.12 shows that the size of the position grammar is polynomially bounded, since we have at most polynomially many transformations and compactions. It is now easy to see that a single rule application: transformation, simplification, compaction, and compaction failure rules, can be done in polynomial time, hence a pot-meta-transformation can be performed in polynomial time.

We conclude that the algorithm WOPS requires polynomial time depending on $|G|$.

The maximal exponent in the polynomial is at least 6 , however, a thorough estimation of the exponent is not possible, since I did not find any estimation in the literature of the degree of the polynomial of the worst case running timer of Plandowski's algorithm for context free grammars.
Corollary 9.14. The word problem for tree and context nonterminals in STGs is in $P$.

Proof. For tree nonterminals, this follows from 9.13 . For context nonterminals $C_{1}, C_{2}$ we extend the grammar by new tree nonterminals and the rules $A_{1}:=$ $C_{1}[a], A_{2}:=C_{2}[a]$, where $a$ is a fresh constant. Now Theorem 9.13 shows that the complexity is polynomial.

Potential Optimizations The algorithm $W O P S$ has a potential for optimizations, which we will not include, e.g. the following rules would be advantageous.

- Do not expand ( $D, D, \varepsilon$ ), where $D$ is a tree or context nonterminal. I.e., move this triple immediately to $S_{\varepsilon, \text { closed }}$.
- Fail if there is $(A, A, N)$, where $A$ is a tree nonterminal, $w_{N} \neq \varepsilon$.
- Fail if there is $(C, C, N)$, where $C$ is a tree nonterminal, and $m p\left(w_{C}\right) \perp w_{N}$.

## 10 Conclusion and Future Work

It is shown that in a sharing representation of terms, sharing subterms and unary contexts where also composition of contexts is permitted, it is possible to
compare the represented terms for equality in polynomial time. The base are singleton tree grammars with (unary) contexts as a generalization of Plandowski's singleton grammars.

Applications of this work may be in determining an improved upper bound of the complexity of stratified context unification and bounded second order unification, which are conjectured to be NP-complete. More practical applications may be in implementations of Automated Deduction Systems using a term representations with exponents, or using a representation with sharing of terms and contexts and exploiting the polynomial equality test to ensure a unique representation.

Future work is to exhibit the smallest degree of the necessary polynomial in the complexity and to optimize the algorithm; this, however, requires to first exhibit the degree of the worst case running time of Plandowski's algorithm. Another direction of future work is to investigate whether the polynomial complexity also holds if contexts with multiple holes or if nonlinear term functions instead of contexts are used in the representation.

Another line of research is to investigate the word problem for unordered, labelled trees.
