**Abstract:** The diversity of bryophytes on the different islands of the Azores varies much between 104 and 324 species. Attempts have been made to explain the heterogeneity of the bryoflora. There is a correlation between species numbers and age of the islands in the way that the youngest islands (Pico) has the lowest species numbers in spite of the fact that it is the highest island. The species numbers of the other islands are correlated with the maximum elevation and with the size of the islands. The liverwort-moss ratio varies between 1.21 and 1.67 and shows a distinct humidity gradient between the islands. The floristic affinities between the islands are calculated by a cluster analysis. They show no correlation with the location of the islands (nearest neighbour), size, age, elevation or species numbers, which indicates that the species composition is mainly determined by chance. Ten species (2,3%) are endemic to the Azores and 14 species (including one genus) are endemic to the Macaronesian Islands. Some of the endemics are questionable, others may occur elsewhere in the tropics under a different name, but there is fossil prove that the others are relicts from the Tertiary which survived extinction during Quaternary in Europe.

### 1. Introduction

Young volcanic islands are an excellent model for phytogeographical questions. An interpretation of their bryofloras can help to find answers for questions such as:

1. „How could the bryophyte species reach these islands ?“ Is it true that only species with diaspores are able to colonize remote islands and only those with small diaspores enabled for long distance dispersal?
2. „When did the species reach the islands ?“

3. „Is there a correlation between the age of the islands and the species numbers?“ (in the way that the oldest islands are the richest in species).

4. „Is there a correlation between the size and the islands and the species numbers?“

5. „Is there a correlation between the elevation and the species number?“

The first question can be answered by an analysis of the presence of dispersal agents such as spores or brood bodies. But also dispersal by man must be taken into account.

The second question cannot easily be answered. Genetical distances between the island
