12	Running title: Soil Conservation and Condition Framework
13	

14 Abstract

It has long been realised that the conservation of soil capital and ecosystem services are of 15 paramount importance, resulting in a growing case for a change in attitude and policy making 16 in respect of soils. Current UK and EU approaches are risk-based and focused on measures 17 18 to manage and remediate the adverse impact of current policies and practices directed at 19 maximising productivity and profit, rather than one of resource conservation. Increasing soil loss and degradation is evidence that current policy is not working and a new approach is 20 needed. In the UK there is governmental ambition to progress towards natural capital led 21 22 land use policies, but, in the absence of a framework to determine the relative condition of the 23 soil resource, the delivery of sustainable soil conservation policies will continue to be inhibited. Common Standards Monitoring (CSM) is an established monitoring and 24 25 management framework (based on ecosystem structure, function and process) and has been effectively deployed for almost two decades by the UK Government for the monitoring and 26 27 reporting of key biological and earth science natural capital and ecosystem services from 28 'field' to local, regional and national levels to the European Commission. It is argued that a 29 CSM for soils could be developed for the UK's soil resources as well as for those elsewhere, and would be able to deliver a conservation rather than the current risk-based approach. It is 30 capable of- accommodating the complexities and variation in soil types and functions, and 31 32 potentially being practical and cost effective in its implementation.

33

Key Words: soil resources, common standards monitoring, natural capital, ecosystem
 services, land degradation

36

38 Introduction

The importance of the soil-natural capital of soil and ecosystem services for the wellbeing 39 and prosperity of past civilisations and contemporary society has been well articulated 40 (Leopold, 1949; Richter & Markewitz, 2001; Diamond, 2005; Montgomery, 2012). The 41 42 scale of land and soil degradation affecting soil capital and the provisioning of food, fibre and 43 other essential services is longstanding and global in its extent (Jacks & Whyte, 1938; Lowdermilk, 1953). Whilst climate and other drivers can be important factors, land use and 44 management practice are considered to have been the main agents; driven by humans, their 45 46 population growth, socio-economic and political aspirations, and cultural attitudes (Leopold, 1949; Stocking & Murnaghan, 2001; Stika, 2016). In 1935, the US Government was the first 47 to attempt to address the agricultural degradation of soil capital and services with the 48 49 formation of a dedicated national Soil Conservation Service (SCS) (Helms et al, 1996; Natural Resources Conservation Service, 2016). On a global scale, this was followed nearly 50 51 sixty years later by the formulation of land use and soil conservation planning and management policy objectives of Chapters 10 and 14 of the Rio Summit Agenda 21 (United 52 53 Nations Environment Programme, 1992), and more recently 'The World Soil Charter' (FAO, 2015). Despite all of the 178 attending governments being in agreement to the outcomes of 54 the Rio Summit, the impact of the past intentions seems to have been minimal given the 55 56 continuing extent of land degradation and the potential to increase further with climate change (Montanarella et al., 2016). 57 Leopold (1949) and Hyams (1952), and more recently other commentators (Conford, 1988; 58 59 Stocking & Muranghan, 2001; Montgomery, 2012; Stika, 2016), have suggested that a 60 fundamentally different approach to land and soil use is required to maintain local and global natural soil capital and ecosystem services. A simple scan of the current scientific literature 61 62 about soils and their use, not unsurprisingly because of the need to feed the growing human

population and concomitant commercial aspirations, indicates it is largely focused on the
measures to maintain productivity and profitability despite there has been a growing literature
about the importance of soil ecosystems. At our cost, the consequence of simply mitigating
the adverse effects of the current production led system will be to perpetuate current thinking
and policy making, without fundamentally changing how we view our finite land and soil
resources.

What sort of system this should be and the how changes and risks should be measured can
only be answered by having an appropriate framework in place (Brouwer & Crabtree, 1999;
Prager, Helming & Hagedorn, 2011). The purpose of this paper is therefore to explore the
case for applying an existing ecosystem-based approach to soil resource conservation and
management to direct future UK and EU policy making.

74 Soils in the European Policy Context

75 In the European context, the current farming-based system arose because of the significant 76 increase in population due to industrialisation and urbanisation, and the need to strive for self-sufficiency in food supply during and following World Wars I and II. The manifestation 77 78 of the current adverse environmental and soil related impacts on soil capital and ecosystem services in the UK and mainland Europe are accepted to be a result of the introduction and 79 80 widespread use of chemicals (fertilisers and pesticides) and developments in mechanisation since the 1960s and 1970s (Parliamentary Office of Science and Technology, 2006; Haygarth 81 82 & Ritz, 2009; Prager et al., 2011; Graves et al., 2015; Smith et al., 2015; Environment Audit Committee, 2016a & b; Kibblewhite et al., 2016). 83

84 Whilst there are continuing land degradation issues such as loss of soil carbon, soil erosion

- and compaction across Europe and the UK (Kibblewhite *et al.*, 2016), there remains no
- specific soil conservation framework for land and soil use policy, despite an attempt to

87	establish one (Commission of the European Communities, 2006). Hence, soil related policy
88	remains largely secondary and consequential, being the result of other environmental
89	objectives (particularly biodiversity, air and water quality). For example, compliance with the
90	EU Common Agricultural Policy (CAP) legislation, specifically the obligation to maintain
91	'good agricultural and environmental condition' (GAEC) in order-to receive agricultural
92	subsidies is mitigation driven and aimed at minimising impact on the environment and soils,
93	whilst maintaining land use and production practices (Louwagie et al., 2011; Prager, Helming
94	& Hagedorn, 2011; Prager et al., 2011; Prosperi et al., 2011; Verspecht et al., 2011). It is
95	within this context that UK and EU policy has been developed and exercised with both
96	environmental and economic adverse consequences (Posthumus et al., 2011; Graves et al.,
97	2015).

98 Framework for Future UK Policies

99 Policy Development

From the late 1990s, government policy policy making in the UK became more explicitly 100 evidence informed (Davies, 2004). This shift in the process theoretically extended to those 101 102 policies which are land-use and soil-based. However, until very recently with the 103 development of natural capital and ecosystem services concepts, UK Government policy and vision (in respect of safe-guarding the UK's soil natural capital) gave little consideration for 104 to the capacity (health) of soil resources to function. Here, the policy drivers were primarily 105 106 concerned with maintaining profitable returns from agricultural production, reducing 107 pollution and the legacies of contaminated land (particularly in relation to human health) 108 (DEFRA, 2009). However, The Natural Choice White Paper (UK Government, 2011), the UK National Ecosystem Assessment (2011), and the Natural Capital Committee (2013) 109 together reset the UK Government's vision for future policy making by introducing soil in the 110

context of critical natural capital which supports crucial health and social, economic and
environmental ecosystem services. This value-based thinking has the potential to direct
future advice and content of government policy making for land use and soils, but not how it
should happen.

115 Concerns have been expressed to the UK House of Commons' Environmental Audit 116 Committee (Environmental Audit Committee, 2016a) that land use policies and visions for 117 the environment and for profitable farming in the forthcoming Department for Environment, Food and Rural Affairs' (DEFRA) Environment Plan (see UK Government, 2016) are in 118 119 danger of continuing to be treated as separate entities despite emanating from the same 120 government department. It is evident from the published departmental plan for 2015-2020 that the UK government's strategic approach continues to be management focused on 121 122 reducing the risks of current land use policies and practices on soils. This suggests that the 123 transition to a holistic natural capital and ecosystem services thinking is not taking place. 124 Hence, the UK Government has yet to resolve the conflicting tensions between their 125 environmental objectives and those for food and farming in its forthcoming 25-year 126 environmental plans (Environmental Audit Committee, 2016b). Some in the UK see it being resolved by a policy of designating 'spare land' (i.e. partitioning of land use) for 127 128 environmental functions (e.g. pollution and flood control, biodiversity), from those allocated 129 for intensive food and fibre production (Garnett & Godfray, 2012; Fairbank et al., 2013). 130 Others, consider alternative production systems will be necessary (Smith, 2013). In such a policy framework, it would seem that greater intensification and efficiency measures are 131 132 envisaged so that UK agricultural profitability and competitiveness are at least maintained (Barnes & Thomson, 2013; Fish, Winter & Lobley, 2014; DEFRA, 2017). Meanwhile, the 133 EU's CAP 'greening' subsidy policy aims to off-set the damage to and degradation of soils 134 and their ecosystems (European Union, 2013). How this approach is supposed to resolve the 135

136 conflicts between sustainability and production will remain uncertain until there is a soil

138 As pointed out by the UK Natural Capital Committee (2013), if there is to be progress there

139 needs to be an evaluative framework in place whereby the assets can be defined and changes

140 and risks to the natural capital and ecosystem services can be measured. The recent review of

soil capital and soil health put to the UK House of Commons' Environmental Audit

142 Committee (Environment Audit Committee, 2016a) established that for both the

143 environmental and farming aspects of land use and soils there are no frameworks fit for

144 purpose currently in place. This raises the question of what basis could a newly focused plan

and policy on soil natural capital and ecosystem services be formulated and assessed for *both*

146 the environment and farming together?

147 Frameworks & Indicators

Frameworks provide the basic structures for concepts or systems, whereas indicators are the
parameters or values, which describe states and fluxes within the concepts and systems, and
their frameworks (OECD, 1994 & 1999).

151

The current framework for assessing and monitoring soil conservation is determined by 152 153 current EU policy (European Union, 2013). There has been much published over the past 154 twenty years on the selection and use of possible indices and indicators of soil health and soil quality in relation to the evaluation of current policies (see Brouwer & Crabtree, 1999; 155 Paoletti, 1999; Pankhurst et al., 1997; Rickson, et al., Undated; Natural England, 2015; 156 Kibblewhite et al., 2016; Schroder et al., 2016). For example, soil carbon is now commonly 157 158 used as an indicator of soil health owing to its functional relationships with soil aggregate stability and soil erosion, soil fertility, and its relevance to the global carbon cycle with 159

respect to atmospheric carbon fluxes and climate change (Smith *et al.*, 2015). Others have
considered the use of soil physical indicators such as bulk density with largely inconclusive
results (e.g. Corstanje *et al.*, 2016) and even operational measures such as the trafficability
(i.e. accessibility) of land for cultivation (Bouma & Wösten, 2016).

Whilst <u>Although</u> the deployment of such indicators enable the formulation of management practices and remedial actions, they have largely been concerned with the resilience of soils to productive farming policies and practices. As Rickson *et al.* (2012) point out, there is the question of whether individual quantitative indicators can ever be related to ecosystem services, let alone being the basis for a conceptual model. What is needed is an overarching framework, which considers soil condition (health) at its core and values the soil at least as much as the livelihood and wealth derived from it.

171 With the possibility of greater land use intensification and efficiency measures, it seems 172 almost inevitable that separate frameworks for the environment and farming will be proposed despite the call for a holistic approach to soil conservation (Usher, 2005; Parliamentary 173 174 Office of Science and Technology, 2012a). A more holistic approach to soil conservation would be to consider all land uses and soils together. Only when this is established, can 175 176 appropriate indicators be identified and applied. Graves et al. (2015) suggested the development of the Landis based 'Soilscape' (Cranfield University, 2017a) as an integrator of 177 soil textural and habitat types and Kibblewhite et al. (2014) used this to assess the spatial risk 178 179 of soil erosion in England and Wales. However, currently, the application of Soilscapes for 180 policy making is limited as it is not real-time based and cannot differentiate between land use 181 histories on a land utilisation basis (i.e. individual fields or parcels of land).

182

A Soil Condition-Based Framework 184

185	Importantly, any re-thinking should be independent and based on principles and evidence,
186	and not governed by commercial self-interest and/or political malaise. An ecological-based
187	approach is most compelling as soils are part of the plant-soil land-based ecosystems (Jenny,
188	1980). Such an approach is timely given the renewed interest in the nature and functioning of
189	soil ecosystems and services (Bardgett et al., 2005; Bardgett & Wardle, 2010; Wall, 2012),
190	and sits well scientifically with the concept of healthy (functioning) soils from a land use
191	perspective (Pankhurst et al., 1997; Doran & Zeiss, 2000; Wall, 2012) and that of ecosystem
192	services.
193	Any new framework will need to encompass and recognise both agricultural and non-
194	agricultural soils as part of the wider UK resource capital as a whole and not treat them as
195	separate entities in policy formulation, as is the case at present. It would also need to
196	recognise self-maintaining plant-soil systems as those which have the full cyclic elements of
197	primary production, decomposition and cycling, along with their attendant biological
198	components (Bardget et al., 2005; Wall, 2012). Such situations are manifest in the form of
199	mature largely undisturbed semi-natural woodlands, grasslands, and other habitat types found
200	across the UK (JNCC, 2010). In these states soils are likely to maintain their fully
201	functioning ecosystems in terms of nutrient cycling, biodiversity etc. Although Whilst
202	somesome of these habitats are used commercially for food and fibre, such as rangeland
203	grazing or rotational harvesting of timber, these are likely to be undertaken with little
204	intervention and disruption of the ecosystem processes that support their ability to function
205	and provide services.
206	Land use practices such as the repeated cultivation of soil, application of quantities of

- 207 artificial-manufactured fertilisers and manures, and establishment of mono-cultures are

208 known to lead to the alteration and degradation of soil ecosystems, and ultimately their

209 dysfunction and reduced service provision (Graves et al, 2015; Smith *et al.*, 2015;

210 Environmental Audit Committee, 2016a). Hence, the<u>re are</u> concerns about erosion,

compaction, degradation of soil structure and loss of soil carbon in the UK and the

212 concentration on policies which remediate and minimise their occurrence (Posthumus et al.,

213 2011; Verspecht et al., 2011; DEFRA, 2016; Kibblewhite et al., 2016).

It is evident from the above that there is sufficient understanding of soil ecosystem

composition and functioning to be able to ascribe diagnostic traits to indicate soil health of

216 habitats and land use types. A fully functioning ecosystem will be associated with definable

traits which that would signify healthy soils and differentiate them from dysfunctional ones.

218 It is notable that the metaphor 'health' has been used to confer a condition in relation to soils

and UK policy (DEFRA, 2009), but not synonymously with ecosystem function.

220 An Existing Ecosystem Condition Framework

221 An existing framework and methodology known as Common Standards Monitoring (CSM) provides a standard and consistent approach for the evaluation of the conservation status and 222 223 dynamics for the long term maintenance and risks to the integrity (extent) and supporting functional attributes (structure and natural processes, regeneration potential, distinctiveness) 224 225 of important biological resources (JNCC, 2004a). The CSM was initially developed for the UK's semi-natural resources such as Upland Upland Grasslands grasslands, 226 227 Woodland woodland and, Miresmires, but later being extended to earth science geological capital. CSM defines the ecosystem's attributes and the conservation objectives, and sets 228 229 targets for judging the current condition according to defined terminology (Favourable/Unfavourable/Destroyed) and-relative to a past condition, thereby providing an 230

231 indication of trend (Maintained, Recovering/Declining). Importantly, CSM provides a

methodology for practical application at a scale ranging from individual features to larger 232 catchment, regional and national scales. The outcomes can be presented as tabulated data 233 234 and/or as maps that can be interrogated and used in strategic policy making, management 235 planning and reporting the effectiveness of their implementation (Williams, 2006). 236 A soil resource-based CSM would also be based on habitat or A and use feature-based. Here, 237 the conservation objectives would be to maintain the integrity of the entirety of the feature's 238 soil resource of that feature and the favourable status of the ecosystem's structural, biological and regenerative functional attributes. The soil conservation status and trends can be inferred 239 240 from well-established associations with habitat type and land use practice. For example, the favourable condition of structural integrity and functioning of soils is known to be maintained 241 in the long-term absence of or infrequent disturbance (e.g. cultivation) of the soil, along 242 243 together with the maintenance of the functional biological processes with persistent vegetation cover and diversity, and root longevity (Bardgett et al., 2005; Bardgett & Wardle, 244 245 2010; Stockdale & Watson, 2012; Natural England, 2015). Conversely, soil structure and 246 biological capacity are degraded by disturbance and certain cropping practices, resulting in 247 unfavourable soil conditions and which, in agricultural practice, are often a focus of 248 intervention or changes in practices to mitigate and maintain production levels (Watts et al., 249 2001; Roger-Estade et al., 2004; Hamza and Anderson, 2005; Bilotta et al., 2007; Batey, 250 2009; Alvarez et al., 2012; Ball et al., 2012; Munkholm et al., 2013; Osman, 2013; 251 Abdollahi et al., 2014; Cui et al., 2014; Abdollahi et al., 2015). Soil ecosystem recovery is 252 possible, but dependent on time and the reinstatement of favourable habitats and land use, 253 and (if needed) intervention practices. Hence, soil condition can be inferred from the feature's habitat type and land use history of the feature, which can be collected by remote 254 sensing, historical records and numerous local and national data bases, site inspection, 255 interview and census. 256

257	The following is work in progress, however, it is set out here for illustration of the mechanics
258	of a soil-based CSM approach to soil resource conservation Conservation objectives, for
259	each of the feature's attributes of the feature would be set to maintain the integrity of the
260	physical extent of the resource, and the functioning of its structural composition and natural
261	processes, potential for regeneration, and, where appropriate, the local distinctiveness of
262	particular soil types, associations and geomorphological features etcamong others. (Table 1).
263	Threshold limits would be set to enable the evaluation of the conservation status and
264	established trends. For the extent and distinctiveness of soil resources, these can be directly
265	determined, but for the other attributes it is anticipated that they can be determined indirectly
266	from the extensive and long established scientific evidence-base supporting associated
267	habitats and land use histories.
268	Soils used for agricultural cropping could be a separate land use or /ecosystem category.
269	WhilstAlthough, such soils are equitable to disturbed land, if the intent is for cropped land to
270	be a functional land use (rather than a transitionary state, such as like glacial moraines) it
271	would be expected to have structural and process <u>or</u> functional attributes that equated with a
272	'favourable' and sustainable soil condition. It could be argued that cropped soils having
273	'Good' structural characteristics (according to visual evaluation methods (e.g. Ball &
274	Munkholm, 2015)) could qualify as being in a functional and hence favourable condition,
275	whereas, 'Poor' soils would be intrinsically unfavourable. Such outcomes would take into
276	account soil-type potential and agricultural practice. In this respect, there is seemingly a
277	strong association between risk of soil erosion and run-off, and cropping and land-use
278	practices (Table 2). The likelihood of cultivated soils being in a favourable condition could
279	be assessed from land use practice and histories, and verified using visual evaluation
280	methods. Hence, cropped land need not necessarily rank lower than other land, but would be

281 a function of climate, land use practice, soil type and landscapes (Environmental Agency,

282 2007).

283	Table 3 provides an illustration of the CSM approach for some habitat features and their
284	hypothetical land use histories. Here, outcomes range from where the soil resources were
285	being maintained in a <u>'F</u> favourable condition', to those in Uunfavourable recovering' and
286	<u>'declining Declining'</u> conditions, and those in <u>'F</u> avourable recovered' or <u>'Uunfavourable no</u>
287	change' states (where intervention measures might have been applied). Where particular
288	types of soils are of uncommon occurrence or perform special (environmental) functions, the
289	integrity of these assets would be part of the reporting process.

290 Discussion

- 291 As CSM is process-based, the principles are capable of being extended to general situations, other than the legally designated nature conservation and geological sites in the UK for which 292 293 it was originally developed. For example, it has been successfully applied in a general context of assessing ecosystem health in the rehabilitation of highly disturbed land after 294 295 mining (Humphries, 2014; Humphries, 2016). Hence, it is argued here that a CSM-like 296 approach based on habitats or land use and integrity or functional attributes would provide 297 for a generally applicable and possibly a more 'global' approach for the long-term monitoring 298 and management of UK and EU soil resources.
- The development of a soil-based CSM approach could enable an inventory of the local and national extent and condition of soil capital in the UK and elsewhere. It could contribute significantly to the formulation and monitoring of protection and strategic policies, and the evaluation of their effectiveness. For example, future policies might encourage and even support the conversion of arable usage to woodland or grassland land uses that are unnonintensive, grassland land uses where particular types of soil or climate change make

Formatted: Font: Not Italic intervention practices less effective and there is a high risk of degradation and/or loss of soil
resource (Environment Agency, 2007).

Prioritisation and Division of Responsibility

307

308 As introduced earlier, the importance of soils and the risks to the future of the Earth's finite 309 land resources has have long been argued by influential members of the land user and 310 scientific communities. This has been acted upon by some government bodies and 311 intergovernmental organisations, such as the EC, UK and FAO, but with arguably mixed 312 results. Despite the continuing accumulation of evidence, there is seemingly little sign of a 313 widespread change in the attitudes of policy makers.- Seemingly, too many of those using 314 land see soils as inert entities, rather than as living and supporting ecosystems that-should be 315 conserved and maintained accordingly. As a consequence, it has been argued that current 316 policy making in the UK and the EU continues to be open to short-term exploitative 317 production foci as opposed to long-term conservation of the soil resource and sustainability of its living functions (Environmental Audit Committee, 2016a).- The reasons for the 318 319 seeming lack of prioritising soil conservation are likely to be a complex mix of political and commercial influences, and institutional inertia as illustrated by the failure of EU Member 320 States² failure to agree a Directive for the protection of soil and land (European Commission, 321 322 2016a). Irrespective of the lack of progress towards a EU wide Directive, with the prospect of the UK leaving the EU, there is an opportunity for the UK Government to rethink its 323 approach to soils and land use, and agricultural policy in general (Humphries, 2017). 324 The division of responsibilities for natural resources, environment and land use policy is 325 326 known to contribute to the inhibition of strategic and integrated policy making (Parliamentary Office of Science and Technology, 2012b). This raises the question which bodies or 327

organisations in the UK and the EU should be charged with the development of soils and land

Formatted: Font: Italic, No underline

329	use policy? Should it-such a policy be led by one an organization concerned with the
330	production of food and fibre, rather than one focused on the environment or the conservation
331	of resources, or should it be a new body? Delegation of responsibility will probably not be
332	enough and satisfactory progress may only be made by legislation for the conservation of soil
333	resources; as has been the case for biodiversity and water resources in the EU and its
334	transposition into the UK Statutes. The science-based lead for the conservation of
335	biodiversity natural and earth science natural capital, and the deployment of the CSM in the
336	UK is by DEFRA's conservation advisory body, the Joint Nature Conservation Committee
337	(JNCC). <u>The JNCC's</u> current advisory remit <u>of JNCC</u> for influencing government policy
338	could be widened to include the conservation of soil resources.

339 A Risk Based or Conservation Approach

340 The proposed EC Directive on soil protection (European Commission, 2006) was founded on 341 a risk-based approach and measures necessary to protect soils from wind erosion, reduction in 342 soil organic matter, compaction, salinization, landslides and contamination in order that they 343 have the capacity to carry out their environmental, economic, social and cultural functions (i.e. soil ecosystem provisions and services). This risk-based approach was adopted by 344 345 DEFRA (2009) in their strategy for safeguarding soils in the UK. The approach has been 346 criticised for being inadequate for future soil conservation policy making by some of those making submissions to the Environmental Audit Committee (Environmental Audit 347 Committee, 2016a). 348 349 The risk approach taken by the EC is strikingly different from that of conservation for

biological resources enacted by their Habitats Directive (European Commission, 1992), and

- 351 appears to reflect the focus and expertise of the stakeholder communities involved. For
- 352 example, there was no legal requirement of the Member States to have in place policies and

Formatted: Font: Italic, No underline

353	actions that aim to maintain their soil and land resource in a favourable biological condition,
354	other than when there are threats to the provisioning and service capacities (which may be
355	provided for in less than favourable circumstances). Importantly, there were no requirements
356	for conservation objectives and targets to be set, nor the monitoring and reporting of the
357	conservation status and longterm dynamics, as for the Habitats Directive. Notably, it was to
358	be left to the Member States to decide and administer, thereby frustrating the development
359	and enactment of an EU wide soil conservation policy.
360	The Habitat Directive imposed a legal requirement on Member States to monitor and report
361	on the long-term maintenance of a favourable conservation status of nationally and
362	internationally important biodiversity capital in the European Union. In response, the UK
363	Government's nature conservation advisor, the JNCC, devised a condition-based framework
364	and methodology which were subsequently adopted by DEFRA (Rowell, 1993; JNCC,
365	2004a; JNCC, 2017). The approach has been accepted by the European Commission as being
366	compliant with the Directive's monitoring and reporting requirements at the pan-European
367	and international levels (Williams, 2006). The CSM framework and methodology has also
368	been applied by the JNCC and adopted by DEFRA for evaluating the conservation status of
369	the UK's important earth science (geology and geomorphology) natural capital (JNCC,
370	2004b). Importantly, the JNCC has used CSM to inform DEFRA's policy making and
371	monitoring of policy outcomes, as well as for the management of the natural capital and for
372	strategic planning and budgeting purposes. Here, it is argued that the CSM approach is
373	potentially of has wider geographical and natural resource application than just the UK and
374	biodiversity, and could inform future policy making for a more 'global' approach to the
375	conservation of soil resources.

376 *A Resource Rather than a Classification Approach*

Formatted: Font: Italic, No underline

377	The UK's vegetation is a complex of different community compositions, mixes, gradients and
378	mosaics represented by the National Vegetation Classification (Rodwell, 2006), similarly the
379	multitude of types of European vegetation communities <u>approach</u> (Mucina et al., 2016). The
380	CSM approach avoided the difficulty posed by the complexity and stricture of classification
381	by being broad habitat and land use based. The soil-based CSM could use the same
382	approach. Hence, the inherent complexity of the types of soils and their classifications
383	(Kubiëna, 1953; Soil Survey Staff, 1960; Clayden and Hollis, 1984; Buol et al., 2011), that
384	has seemingly frustrated the formulation of the European Commission's proposed Soil
385	Directive, should also not be a conceptual bar to the deployment and the development of the
386	CSM approach for national and pan-national applications. Where there are distinct traits or
387	particular conservation or ecosystem service qualities of particular soil resources, these could
388	be accommodated by the CSM methodology, as has been the case for the UK's nature
200	conservation assets.

 390 391 392 393 394 395 396 397 398 	Adoption of the CSM approach is likely to be criticised on account of over simplification of the complexity of soils and their condition. Here, there are basically two contrasting mindsets of how this is approached by scientists and practitioners alike. There are those who are concerned in the detail and accounting of the contributing individual factors, whilst whereas others approach it as their aggregate, as processes <u>for</u> functions (see Sherwood & Uphoff, 2000; Kibblewhite <i>et al.</i> , 2008). Inherently, CSM is an aggregated approach as <u>is are</u> the visual soil evaluation methodologies of soil condition (see Ball & Munkholm, 2015). The same arguments of over simplification of the complexity and variation between soil types and characteristics could be levelled in the application of visual approaches such as

402	methods for both practitioners and academic researchers. The approach has been adopted by	
403	the UK's Environment Agency in its 'Think Soils Manual' guidance to farmers for reducing	
404	soil loss and degradation (Environment Agency, 2007). In essence the CSM approach could	
405	be considered as an extension of the visual evaluation family.	
406	Also, the functional ecosystem focus of the CSM approach for evaluating the condition status	
407	of nature conservation assets is in concert with the more recently developed and widely	
408	proffered ecosystem services soil health approach, that which seems to be replacing the risk-	
409	based approach. Both CSM and ecosystem services are founded on similar ecosystem	
410	function attributes of cover (extent), soil structure, biological composition, nutrient cycling,	
411	and recuperation, all being necessary for 'healthy' ecosystems (JNCC, 2004a; Kibblewhite et	
412	al., 2008). Notably, both CSM and ecosystem service approaches are not based on	
413	reductionist hierarchical classifications of composition.

However, its deployment, other than at the local scale and/or very limited sampling, requires considerable investment of time, and technical and financial resources, as would the wholesale deployment of qualitative visual techniques (see Ball & Munkholm, 2015). This <u>sampling limitation</u> and the restriction to a few easily	

Survey, 2017; Cranfield University, 2017b) the parameters available may not be appropriate 426 427 for the development and evaluation of policies or a changing environment (Keay et al., 428 2013), besides issues concerning the standardisation of methodologies (O'Sullivan et al., 429 2017). In practice, the conventional sample-based approach is more suited for research and 430 verification purposes. 431 The ecosystem services approach is also said to be based on the selection and periodic 432 analysis of independent sample-based indicators (Kibblewhite et al., 2008), making it 433 uncertain how an evaluation might be arrived at. CMS relies on existing research knowledge 434 and established associations of soil condition with habitat and land use practices, similar to those proposed by Sherwood & Uphoff (2000). Hence, potentially, the CMS approach does 435 not have the same financial and practical limitations as sampling-<u>for</u> analytical 436 437 methodologies. Past and current habitat and land use data would be collected on a real-time 438 (annual) basis from existing historical records, remote sensing and annual returns. 439 Consequently, development costs and time will be low small and short. There would be no 440 need for the time consuming and costly repetition of the extensive collection and analysis of 441 samples; other than initially and for updating, in the setting and refining of conservation targets, limits and ranges associated soil-habitat or *4* and use during the development of a soil-442 443 CSM. Of course, an ongoing and structured sampling programme for quality control 444 purposes and verification of conservation status would be needed, as would be the case for any approach. 445 In the UK and the EU an administrative infrastructure already exists for the national reporting 446

of land use through the implementation of the CAP payment system, which could be reengineered. In the UK this is currently provided by DEFRA's Rural Payments Agency or the
Member Country's own agencies. Alternatively, implementation and administration might

become an expansion of the remit of DEFRA's JNCC and the UK's Country conservationagencies.

452 Finally, in preparing the above argument for the adoption of the CSM approach to soil 453 conservation policy, it has rightly been pointed out (during the peer review process) that there 454 will be technical, socio-economic and political concerns that will need to be answered in 455 more detail before it is likely to become widely accepted. For example, the reliance on habitat-or land use practice as the basis of assessment of soil condition as opposed to the 456 traditional approaches based on soil types and their origin. Also, there is the concern that the 457 458 CSM approach is inherently biased against the agricultural use of soils and would place the 459 priority of soil conservation above food production with the concomitant result of lower 460 levels of production and the implications this has for commerce and living standards. These 461 and other considerations are clearly relevant and will need to be debated and addressed as the methodology is trialled and developed. These matters are beyond the scope of this paper; 462 463 given that its purpose was simply to introduce the CSM methodology for developing soil 464 resource conversation policies.

465

466 Conclusions

For some time there has been a growing case for a change in attitude and policy making in
with respect of to the UK's and the EU's soil resources. A change from a production to a
sustainable soil resource and function perspective could drive this. It could might be better
facilitated by approaching soils as a matter of resource conservation rather than risk
management.

472 CSM is an existing and proven conservation-based framework and methodology which is473 currently used in natural resource management and for policy making. The same approach

474	could be deployed to set the conservation objectives and report on the status of soil resources
475	consistently at individual local features as well as at national scales. A soil-based CSM is
476	complementary to and supportive of the emerging policy drivers of ecosystem services and
477	natural capital.

- 478 A CSM for soil resources <u>could-would</u> be quick and cheap to develop, and has the potential to
 479 be simple to administer and cost effective, and capable of being implemented through
- 480 existing UK and EU governmental administrative 'infrastructure'.
- 481 Whilst <u>Although</u> acknowledging there are likely to be concerns about the adoption of a
- 482 conservation approach to soil resources and policies governing their use, there are compelling
- reasons why a soil-CSM should be explored and debated further.

484 Acknowledgements

- 485 The initial development of the CSM methodology (for the UK's nationally important nature
- 486 conservation assets) in the early 1990's was largely by Drs. Tim Read (formerly Joint Nature
- 487 Conservation Committee) and Terry Rowell (formerly English Nature). We thank both
- anonymous referees for their informative and constructive critiques of our initial and revisedmanuscripts.

791 Table 1 Draft generic CSM guidance on conservation objectives for soil resources

FEATURE ATTRIBUTE	CONSERVATION	TARGET / THRESHOLD	METHODS OF	COMMENT
	OBJECTIVE	TARGET / TIMESHOLD	ASSESMENT	COMMENT
Extent	Maintain topsoil cover and topsoil resource	No significant physical loss to erosion, change in use or development	Direct by remote sensing / survey / historical records / census	Change would be determined by a pre-set date
Structural composition	Maintain potential climatic and textural soil structure development	No significant degradation	Indirect by association with current and historic habitat and land	Inferred status determined from literature and updated
Natural Processes	Maintain carbon transformations, nutrient cycling and biological population regulation	No significant degradation	use practice determined by remote sensing / survey / historical records / census	from verified experience. Scope for intervention measures to be included.
Regeneration Potential	Maintain persistent complete plant cover, diversity of plant species and continuity of living root system	No significant degradation	Indirect by association with current and historic habitat and land use practice determined by remote sensing / survey / historical records / census	Inferred status determined from literature and updated from verified experience. Scope for intervention measures to be included.
Indicators of Local Distinctiveness	Maintain soils of local and uncommon distribution and soils having important environmental function	No significant physical loss to erosion, change in use or development	Direct by remote sensing / survey / historical records / census	Does not contribute to the evaluation of conservation state and trend per se, but alerts to provision of other ecosystem services and/or conservation of diversity or scientific interest of resource

Table 2 Land use practices and soil types in the UK at risk of soil erosion and run-off (derived from

795 Think Soils Manual, Environment Agency, 2007)

La	and Use	Soil Type	Conditions	Risk of Erosion	Risk of Run-off
AI	ll cereals	Light	Fine smooth seed beds	When dry and exposed	When capped
AI	ll cereals	All	Harvested when soils		When surface
			wet		compaction / wheelings
w	/inter cereals	All	Seed bed formed when		When surface
			soils wet		compaction or shallow
					underlying compaction
Sp	pring root	Light, Peaty	Soils wet at crop	When repeated	When surface
