

APIM_SEM: Estimating the APIM in a Free Online Shiny App

Lara Stas
Ghent University

Prof. David A. Kenny
UCONN

*In collaboration with:
Prof. Tom Loeys and Prof. Axel Mayer*

Outline

Apps for standard (and complex) APIMs

APIM_SEM: Demo

Two apps for standard (and complex) APIMs

- Different underlying statistical model
 - APIM_SEM: Structural Equation Modeling
 - APIM_MM: Multilevel Modeling
- Identical results
- Minor differences:
 - APIM_SEM:
 - FIML in case of missingness
 - Correction for unreliability
 - APIM_MM
 - Test of Actor-Partner interaction
 - More in depth test of distinguishability

Two apps for standard (and complex) APIMs

APIM: Distinguishable dyads using lavaan

Standard Model

=====

Introduction

The focus of this study is the investigation of the effect of Romantic Appraisal on Satisfaction Wave 2. The dyad members are treated as if they are distinguishable by the variable gender. The two roles used are: Women and Men. Both the effect of own Romantic Appraisal (actor) and the effect of partner's Romantic Appraisal (partner) on Satisfaction Wave 2 are studied. The total number of dyads (N) is 158. There are missing data for one or more of the variables: The number of cases for Women on Romantic Appraisal is 157 and on Satisfaction wave 2 156. For Men the number of cases on Romantic Appraisal is 156 and on Satisfaction wave 2 152. Residuals of the fitted model that are more extreme than 4 standard deviations (absolute value) are called outliers. Based on this data set it can be concluded that the observations of the following row(s) are more extreme than 4 standard deviations: 51, 97. These outliers can be removed from the data set in the Additional tab under the header 'Remove observations'.

Analyses

The analyses use structural equation modeling with maximum likelihood estimation using the program lavaan. The tests of coefficients are 2 tests. Effect sizes for actor and partner effects are partial correlations. Betas are given twice, one using the overall standard deviation across all persons (o) for standardization and a second using the standard deviation for women and men separately (s). If betas are to be compared across members, the beta (o) value should be examined. For all these analyses, alpha is set at 0.05. The descriptive statistics of the raw variables are contained in Table 1 and the FIML estimated means and standard deviations in Table 2 in the output tab 'Tables'. If there are no missing data, the raw and the FIML means should be the same; the FIML standard deviations differ from the raw ones by the square root of $N - 1$ divided by N .

Output: Text output

```
Results
-----
    The lavaan model converged after 32 iterations. A summary of results of the APIM
    analyses is contained in Table 3 and the overall effects in Table 4 in the output tab
    'Tables'. The variance of the errors for the Women and Men are 0.329 and 0.193,
    respectively. The R squared for the Women is .054, for the Men it is .073. The partial
    intraclass correlation for Satisfaction Wave 2 controlling for the other variables is
    equal to .109 and is statistically significant (p < .001, 95% CI [0.06, 0.16]). Thus,
    when one member of the dyad scores high (low) on the variable Satisfaction wave 2, the
    other member also tends to have a high (low) score.

    The intercept (the predicted score on Satisfaction Wave 2 when the variables of
    Romantic Appraisal equal zero) for Women is equal to 3.624 and is statistically
    significant (p < .001, 95% CI [3.53, 3.72]). The intercept for Men is equal to 3.695 and
    is statistically significant (p < .001, 95% CI [3.62, 3.77]). The difference in
    intercepts is equal to -0.071. This difference is not statistically significant (p =
    .122, 95% CI [-0.16, 0.02]), which means that there is no main effect of Gender.

    The actor effect for the Women is equal to 0.236 (p = .003, 95% CI [0.08, 0.39]).
    The overall standardized effect for the Women is 0.266 (partial r = .187 and a small
    effect size). The actor effect for the Men is equal to 0.152 (p = .018, 95% CI [0.04,
    0.27]) and the overall standardized actor effect for the Men is 0.171 (partial r = .258
    and a small effect size). When tested if the two actor effects are equal, the difference
    was found not statistically significant, p = .383, 95% CI [-0.11, 0.28]. The overall
    actor effect is equal to 0.194 and is statistically significant (p < .001, 95% CI [0.1,
    0.29]).

    The partner effect from Men to women is equal to 0.047, which is not statistically
    significant (p = .535, 95% CI [-0.1, 0.2]), and its overall standardized effect is 0.053
    (partial r = .065 less than small). The partner effect from Women to Men is equal to
    0.155 and is statistically significant (p = .016, 95% CI [0.03, 0.28]) and its overall
    standardized partner effect is 0.174 (partial r = .187 and a small effect size). When
    tested if the two partner effects are equal, the difference was found not statistically
    significant (p = .272, 95% CI [-0.3, 0.08]). The overall partner effect is equal to
    0.101 is statistically significant (p = .046, 95% CI [0, 0.2]).

    Next, the relative sizes of the actor and partner effects are considered. If the
    standardized actor effects of both women and Men are greater than .1 in absolute value
    and they are statistically significant, k (i.e. the ratio of the partner effect to the
    actor effect) can be interpreted in the output. This is the case for this data set. The
    value of k for the Women equals 0.2, the k of the Men is equal to 1.02. No further
    conclusions can be drawn for k, because a bootstrap analysis was not chosen to calculate
    the confidence intervals. By allowing the program to calculate the confidence intervals
    by means of bootstrap sampling, dyadic patterns in the Actor-Partner Interdependence
    Model can be detected. In particular, the program can check whether the couple model (k =
    1), actor-only (k = 0) model or the contrast model (k = -1) is most plausible. This by
    checking which value of k (-1, 0, 1) sits in the bootstrapped confidence interval of
    k. If a more complete output were desired, please specify so in the input tab
    'Additional Options'. Please note that the Monte Carlo Sampling technique will be really
    fast, this is the parametric bootstrapping method. The non-parametric bootstrapping
    method (i.e., regular bootstraps), may take a while to calculate.

    Test of Distinguishability:
    In order to test if Gender makes a statistically meaningful difference, a model
    comparison is performed between a model with distinguishable members and a model with
    indistinguishable members. This overall test of distinguishability yields a chi square
    statistic with 6 degrees of freedom which equals 24.57 (p < .001). Because this test of
    distinguishability is statistically significant, we conclude that members can be
    statistically distinguished based on the variable gender.

Graphical Presentation of the Fitted Model

Reactive Figures

The two figures presented below reflect all variables included in the model, also all covariates. If not all estimates are presented clearly, please try to diminish (or enlarge) the size of your browser. The figure will automatically adapt.

Positive estimates are indicated with green arrows, negative estimates with red arrows. The stronger the effect, the thicker the line of the arrow will be. The double headed arrow between "Romantic Appraisal Man" and "Romantic Appraisal Woman" represents its covariance. The double headed arrow between "Satisfaction Wave 2 Man" and "Satisfaction Wave 2 Woman" is the residual nonindependence in these outcome scores, which is represented by the covariance between their corresponding two errorterms.

Standard model:

Model with standardized parameter estimates:

Output: Tables and figures

The two plots below are identical to the ones above, but only show the basic APIM. Covariates and other requested parameters are still estimated, but for simplicity only the estimates of the actor and partner effects are presented, together with the residual nonindependence in the outcome scores. In particular, the estimates, standard error and level of significance are shown.

Standard model:

* $p < .05$; ** $p < .01$; *** $p < .001$

Model with standardized parameter estimates:

* $p < .05$; ** $p < .01$; *** $p < .001$

Check Normality and Outliers

In order to check the normality of the residuals, one can consult the following three plots.

Guidelines for interpretation:

- The density function of the residuals ideally looks bell-shaped.
- The boxplot should look symmetric around zero with limited number of outliers (or none at all).
- For the QQ-Plot, the dots should be situated on or close to the straight line.

Density function of residuals

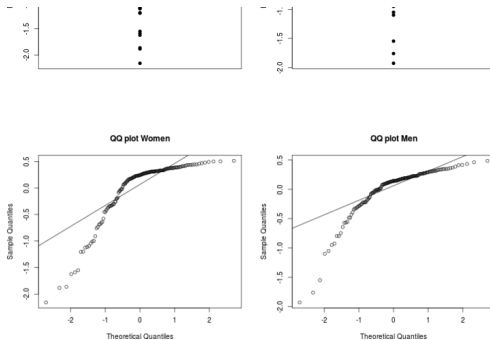

Boxplot Women

Boxplot Men

Output: Diagnostics

Effects in Raw Data

The following plots are an exploration of actor (partner) effects, ignoring partner (actor) effects and the effects of plausible covariates. Stricto sensu, these effects are no real actor (partner) effects since they do not take into account partner (actor) effects. These plots are solely meant for data exploration.

When one is interested in the estimated actor and partner effects of the fitted model, please consult the tab [Figures](#).

APIM: Distinguishable Dyads Using lavaan

Standard Model

Introduction

The focus of this study is the investigation of the effect of Romantic Appraisal on Satisfaction Wave 2. The dyad members are treated as if they are distinguishable by the variable Gender. The two roles used are: Women and Men. Both the effect of own Romantic Appraisal (actor) and the effect of partner's Romantic Appraisal (partner) on Satisfaction Wave 2 are studied. The total number of dyads (N) is 158. There are missing data for one or more of the variables: The number of cases for Women on Romantic Appraisal is 157 and on Satisfaction Wave 2 156. For Men the number of cases on Romantic Appraisal is 156 and on Satisfaction Wave 2 152. Residuals of the fitted model that are more extreme than 4 standard deviations (absolute value) are called outliers. Based on this data set it can be concluded that the observations of the following row(s) are more extreme than 4 standard deviations: 51, 97. These outliers can be removed from the data set in the Additional tab under the header 'Remove observations'.

Analyses

The analyses use structural equation modeling with maximum likelihood estimation using the program lavaan. The tests of coefficients are 2 tests. Effect sizes for actor and partner effects are partial correlations. Betas are given twice, one using the overall standard deviation across all persons (o) for standardization and a second using the standard deviation for women and men separately (s). If betas are to be compared across members, the beta (o) value should be examined. For all these analyses, alpha is set at 0.05. The descriptive statistics of the raw variables are contained in Table 1 and the FIML estimated means and standard deviations in Table 2 in the output tab 'Tables'. If there are no missing data, the raw and the FIML means should be the same; the FIML standard deviations differ from the raw ones by the square root of N - 1 divided by N.

Additional options

Calculating k (*)

Do you want to bootstrap the CI(s) of the k(s)? (**)

Yes

Outliers

Observations more extreme than standard deviations are called outliers

4

Remove observations

Enter the observations (i.e., rows) that you want to delete from the dataset (separated by a comma)

(*) For more info on k, please consult the tab [Extra info](#)

(**) If no bootstrap trials are allowed, no conclusion can be drawn which model suits this dataset the best (actor-only, couple or contrast mode).

Results

The lavaan model converged after 32 iterations. A summary of results of the APIM analyses is contained in Table 3 and the overall effects in Table 4 in the output tab 'Tables'. The variance of the errors for the women and men are 0.329 and 0.193, respectively. The R squared for the women is .064, for the men it is .073. The partial intraclass correlation for satisfaction wave 2 controlling for the other variables is equal to .109 and is statistically significant ($p < .001$, 95% CI [0.06, 0.16]). Thus, when one member of the dyad scores high (low) on the variable Satisfaction Wave 2, the other member also tends to have a high (low) score.

The intercept (the predicted score on Satisfaction Wave 2 when the variables of Romantic Appraisal equal zero) for women is equal to 3.624 and is statistically significant ($p < .001$, 95% CI [3.53, 3.72]). The intercept for men is equal to 3.695 and is statistically significant ($p < .001$, 95% CI [3.62, 3.77]). The difference in intercepts is equal to -0.071. This difference is not statistically significant ($p = .122$, 95% CI [-0.16, 0.02]), which means that there is no main effect of Gender.

The actor effect for the women is equal to 0.236 ($p = .003$, 95% CI [0.08, 0.39]). The overall standardized effect for the women is 0.266 (partial $r = .167$ and a small effect size). The actor effect for the men is equal to 0.152 ($p = .018$, 95% CI [0.04, 0.27]) and the overall standardized actor effect for the men is 0.171 (partial $r = .258$ and a small effect size). When tested if the two actor effects are equal, the difference was found not statistically significant, $p = .383$, 95% CI [-0.11, 0.08]. The overall actor effect is equal to 0.194 and is statistically significant ($p < .001$, 95% CI [0.1, 0.29]).

The partner effect from men to women is equal to 0.047, which is not statistically significant ($p = .535$, 95% CI [-0.1, 0.2]), and its overall standardized effect is 0.053 (partial $r = .065$ less than small). The partner effect from women to men is equal to 0.155 and is statistically significant ($p = .016$, 95% CI [0.03, 0.28]) and its overall standardized partner effect is 0.174 (partial $r = .187$ and a small effect size). When tested if the two partner effects are equal, the difference was found not statistically significant ($p = .272$, 95% CI [-0.3, 0.02]). The overall partner effect is equal to 0.101 and is statistically significant ($p = .046$, 95% CI [0, 0.2]).

Next, the relative sizes of the actor and partner effects are considered. If the standardized actor effects of both women and men are greater than .1 in absolute value and they are statistically significant, k (i.e., the ratio of the partner effect to the actor effect) can be interpreted in the output. This is the case for this data set. The value of k for the women equals 0.2, the k of the men is equal to 1.02. No further conclusions can be drawn for k, because a bootstrap analysis was not chosen to calculate the confidence intervals. By allowing the program to calculate the confidence intervals by means of bootstrap sampling, dyadic patterns in the Actor-Partner Interdependence Model can be detected. In particular, the program can check whether the couple model ($k = 1$), actor-only ($k = 0$) model or the contrast model ($k = -1$) is most plausible. This is by checking which value of k (-1, 0, 1) situates in the bootstrapped confidence interval of k. If a more complete output were desired, please specify so in the input tab 'Additional Options'. Please note that the Monte Carlo Sampling technique will be really fast, this is the parametric bootstrapping method. The non-parametric bootstrapping method (i.e., regular bootstraps), may take a while to calculate.
