## Bi-ideals in associative rings

By S. LAJOS and F. SZÁSZ in Budapest

Throughout this paper, by a ring $A$ we shall mean an arbitrary associative ring. For the terminology we refer to N. Jacobson [5], N. H. McCoy [16] and L. Réder [18]. In analogy to the notion of bi-ideal in semigroups (cf. A. H. Clifford and G. B. Preston [3] vol. I) we shall study some properties of bi-ideals in rings.

For the arbitrary subsets $X$ and $Y$ of a ring $A$ by the product $X Y$ we mean the additive subgroup of the ring $A$ which is generated by the set of all products $x y$, where $x \in X$, and $y \in Y$. By a bi-ideal $B$ of a ring $A$ we 'understand a subring $B$ of $A$ satisfying the following condition:

$$
\begin{equation*}
B A B \subseteq B \tag{1}
\end{equation*}
$$

Obviously every one-sided (left or right) ideal of $A$ is a bi-ideal, and the intersection of a left and a right ideal of $A$ is also a bi-ideal. We note that the bi-ideals in semigroups are special cases of the ( $m, n$ )-ideals introduced by S. LAJOS [7]. He remarked that the set of all bi-ideals of a regular ring is a multiplicative semigroup [10]. Some generalizations of biideals of rings were discussed by F. Szász [22]. The concept of the bi-ideal of semigroups was introduced by R. A. Good and D. R. Hughes [4]. Interesting particular cases of bi-ideals are the quasi-ideals of O. Sternfeld [19]: A submodule $Q$ of an associative ring $A$ is called a quasi-ideal of $A$ if the following condition holds:

$$
\begin{equation*}
Q A \cap A Q \subseteq Q \tag{2}
\end{equation*}
$$

It is known that the product of any two quasi-ideals is a bi-ideal (cf. S . Lajos [8]). It may be remarked that in case of regular rings the notions of bi-ideal and quasiideal coincide (see S. Lajos [10]). It was shown by the first named author that there exists semigroup $S$ containing a bi-ideal $B$ which is not a quasi-ideal of $S$ (see. S . Lajos [13]).

Next we formulate some general properties of bi-ideals in rings. Then we characterize two important classes of associative rings in terms of bi-ideals.

Proposition 1. The intersection of an arbitrary set of bi-ideals $B_{\lambda}(\lambda \in \Lambda)$ of $a$ ring $A$ is again a bi-ideal of $A$.

Proof. Set $B=\bigcap_{i \in A} B_{\lambda}$. Evidently $B$ is a subring of $A$. From the inclusions $B_{\lambda} A B_{\lambda} \subseteq B_{\lambda}$ and $B \subseteq B_{\lambda}(\forall \lambda \in \Lambda)$ it follows that

$$
\begin{equation*}
B A B \subseteq B_{i} A B_{i} \subseteq B_{\lambda} \quad(\forall \lambda \in \Lambda) \tag{3}
\end{equation*}
$$

and consequently we have

$$
\begin{equation*}
B A B \subseteq B \tag{4}
\end{equation*}
$$

This proves Proposition 1.
Proposition 2. The intersection of a bi-ideal $B$ of $a$ ring $A$ and of a subring $S$ of $A$ is always a bi-ideal of the ring $S$.

Proof: Let us assume that

$$
\begin{equation*}
C=B \cap S \tag{5}
\end{equation*}
$$

Since $S$ is a subring and $C \cong S$ we conclude

$$
\begin{equation*}
C S C \subseteq S S S \subseteq S \tag{6}
\end{equation*}
$$

On the other hand

$$
\begin{equation*}
C S C \subseteq B S B \subseteq B A B \subseteq B \tag{7}
\end{equation*}
$$

whence $C S C \subseteq B \cap S=C$.
Proposition 3. For an arbitrary subset $T$ of $a$ ring $A$ and for a bi-ideal $B$ of $A$ the products $B T$ and $T B$ both are bi-ideals of $A$.

Proof. By $T A \subseteq A$ and $B A B \subseteq B$ we have

$$
\begin{equation*}
B(T A) B \subseteq B A B \cong B \tag{8}
\end{equation*}
$$

Moreover, we have the following monotonity property of the product defined in the introduction above:

$$
\begin{equation*}
X \subseteq Y \Rightarrow X Z \cong Y Z \tag{9}
\end{equation*}
$$

for arbitrary subsets $X, Y, Z$ of the ring $A$. Then (8) and (9) imply the relation

$$
\begin{equation*}
(B T) A(B T) \subseteq B T \tag{10}
\end{equation*}
$$

which together with $(B T)(B T)=(B T B) T \subseteq(B A B) T \subseteq B T$ means that the product $B T$ is a bi-ideal of the ring $A$. The proof concerning the product $T B$ is similar to that of $B T$.

In an analogy to the case of semigroups (cf. S. Lajos [8]) we obtain the following result.

Proposition 4. Let $B$ be an arbitrary bi-ideal of the ring $A$, and $C$ be a bi-ideal of the ring $B$ such that $C^{2}=C$. Then $C$ is a bi-ideal of the ring $A$.

Proof. The suppositions $B A B \subseteq B$ and $C B C \subseteq C$ imply

$$
\begin{equation*}
C A C=C^{2} A C^{2} \sqsubseteq C(B A B) C \cong C B C \cong C \tag{11}
\end{equation*}
$$

which proves the statement.
Proposition 5. An arbitrary associative ring $A$ contains no non-trivial biideal if and only if $A$ either is a zero ring of prime order or $A$ is a division ring.

Proof. Suppose that the ring $A$ contains no non-trivial bi-ideals. Then clearly $A$ contains no non-trivial right ideals, and thus $A$ satisfies the minimum condition on right ideals. Suppose that $A$ is not semi-simple in the sense of Jacobson. Then $A$ is an Artinian radical ring, which is nilpotent by a well-known result due to CH . Hopkins (cf. N. Jacobson [5]), and finally $A$ is a zero ring of prime order in absence of non-trivial right ideals. On the other hand, if $A$ is semi-simple then it is a division ring by the famous Wedderburn-Artin structure theorem (cf. Jacobson [5] or Réder [18]), which proves the "only if" part of Proposition 5.

Conversely assume that $A$ either is a zero ring of prime order or a division ring. We shall show that $A$ has no non-trivial bi-ideals. This assertion is trivially true for a zero ring of prime order because every additive subgroup in a zero ring is a twosided ideal. If $A$ is a division ring and $B$ is a non-zero bi-ideal of $A$, then the condition

$$
\begin{equation*}
B A B \sqsubseteq B \tag{12}
\end{equation*}
$$

implies $B=A$, because in a division ring $A$ we have $x A=A=A x$ for every non-zero element $x \in A$, consequently

$$
\begin{equation*}
B A B=B(A B)=B A=A \subseteq B \subseteq A \tag{13}
\end{equation*}
$$

Remark 1. An elementary and short proof of the fact that a ring $A$ containing no non-trivial right ideals either is a zero ring of prime order or a division ring, can be found in a paper of F. Szász [20].

Proposition 6. Let $T$ be a non-empty subset of the ring $A$. Then the bi-ideal of A generated by $T$ is of the form:

$$
\begin{equation*}
T_{(1,1)}=I T+T^{2}+T A T \tag{14}
\end{equation*}
$$

where I denotes the ring of rational integers.
Proof. The verification of the statement is almost trivial and we omit it.

Remark 2. By Proposition 1 the intersection of any set of bi-ideals of a ring $A$ is also a bi-ideal of $A$, and thus the bi-ideal $T_{(1,1)}$ defined above evidently coincides with the intersection of all the bi-ideals of $A$ containing $T$.

Remark 3. By Proposition 6 we have:
(i) The principal bi-ideal $(x)_{(1,1)}$ generated by the single element $x$ of $A$ can be represented as follows:

$$
\begin{equation*}
(x)_{(1,1)}=I x+I x^{2}+x A x . \tag{15}
\end{equation*}
$$

(ii) In the particular case of an idempotent element $e$ of the ring $A$ we obtain:

$$
\begin{equation*}
(e)_{(1,1)}=e A e . \tag{16}
\end{equation*}
$$

(iii) For an additive subgroup $T$ of $A$ one has:

$$
\begin{equation*}
T_{(1,1)}=T+T^{2}+T A T \tag{17}
\end{equation*}
$$

(iv) If $S$ is a subring of the ring $A$ then

$$
\begin{equation*}
S_{(1,1)}=S+S A S \tag{18}
\end{equation*}
$$

Proposition 7. For any associative ring $A$ denote by $\bar{A}$ the set of all additive subgroups of $A$, and $A_{1}$ the set of all bi-ideals of $A$. Then $\bar{A}$ and $A_{1}$ are semigroups under multiplication of subsets (defined in the introduction of this paper), and $A_{1}$ is a twosided ideal of $\bar{A}$.

Proof. The statement of this proposition is an immediate consequence of Proposition 3 and the definition given in the introduction for the multiplication of subsets.

Remark 4. The multiplicative semigroup of all non-empty subsets of an arbitrary semigroup was formerly investigated by S . Lajos [8]. He proved that the set of all bi-ideals of a semigroup is a two-sided ideal of the multiplicative semigroup of all non-empty subsets of the semigroup.

Remark 5. J. Calais [2] gave an explicite example for a semigroup having two quasi-ideals whose product fails to be a quasi-ideal. In this connection it may be remarked that one of the authors, S. Lajos [10] proved that for the case of regular rings as well as for regular semigroups the product of any two quasi-ideals is again a quasi-ideal.

For the verification of the interesting fact that every left ideal of a right ideal of an arbitrary associative ring can be represented as a right ideal of a suitable left ideal of the ring, we shall prove the following statement in analogy to a semigrouptheoretical result due to S. Lajos [7].

Theorem 1. For an arbitrary non-empty subset $B$ of an associative ring the following conditions are pairwise equivalent:
(I) $B$ is a bi-ideal of $A$.
(II) $B$ is a left ideal of a right ideal of $A$.
(III) $B$ is a right ideal of a left ideal of $A$.

Proof. It is enough to prove that (I) is equivalent to (II), because condition (III) is the left-right dual of (II), therefore the proof of the equivalence of (I) and (III) is similar to that of (I) $\Leftrightarrow$ (II).

To show that (I) implies (II), suppose that the subset $B$ is a bi-ideal of the ring $A$. Let $(B)_{r}$ be the right ideal of $A$ generated by $B$. It will be verified that $B$ is a left ideal of the ring $(B)_{r}$. Indeed, the relations $(B)_{r}=B+B A$ and $B A B \subseteq B$ imply

$$
\begin{equation*}
(B)_{r} B=(B+B A) B \cong B^{2}+B A B \cong B \tag{19}
\end{equation*}
$$

Conversely, to prove that condition (II) implies (I), assume that the subset $B$ of $A$ is a left ideal of a right ideal $R$ of $A$. Then the inclusions

$$
\begin{equation*}
R A \subseteq R, \quad R B \subseteq B \tag{20}
\end{equation*}
$$

imply

$$
\begin{equation*}
B A B \subseteq(R A) B \subseteq R B \subseteq B, \tag{21}
\end{equation*}
$$

which together with the obvious fact that $B$ is a subring of $A$ yields the wished assertion.

In what follows we will be concerned with different properties of bi-ideals in special classes of associative rings. Among other things the characterization of some classes of rings will be given by means of bi-ideals.

Theorem 2. For an associative ring $A$ the following conditions are mutually equivalent:
(I) $A$ is regular.
(II) $L \cap R=R L$ for every left ideal $L$ and for every right ideal $R$ of $A$.
(III) For every pair of elements $a, b$ of $A,(a)_{r} \cap(b)_{l}=(a)_{r}(b)_{l}$.
(IV) For any element a of $A,(a)_{r} \cap(a)_{t}=(a)_{r}(a)_{t}$.
(V) $\quad(a)_{(1,1)}=(a)_{r}(a)_{2}$ for any element $a$ of $A$.
(VI) $\quad(a)_{(1,1)}=a$ a for any element $a$ of $A$.
(VII) $Q A Q=Q$ for any quasi-ideal $Q$ of $A$.
(VIII) $B A B=B$ for any bi-ideal $B$ of $A$.

Proof. ${ }^{1}$ ) (I) $\Leftrightarrow$ (II). This was proved by L. Kovács.[6]. It is evident that

[^0]$(\mathrm{II}) \Rightarrow(\mathrm{III}) \Rightarrow(\mathrm{IV})$. The implication (IV) $\Rightarrow$ (I) was proved by F. Szász [21]. Thus we have shown the equivalence of the first four conditions.
$(\mathrm{I}) \Rightarrow(\mathrm{V})$. Assume, that $A$ is a regular ring. Then the solvability of any equation $a \times a=a$ implies
\[

$$
\begin{equation*}
(a)_{r}=(a x)_{r}=a x A \tag{22}
\end{equation*}
$$

\]

and

$$
\begin{equation*}
(a)_{l}=(x a)_{l}=\dot{A} x a \tag{23}
\end{equation*}
$$

where $(a x)^{2}=a x$ and $(x a)^{2}=x a$. Hence

$$
\begin{equation*}
(a)_{r}(a)_{t}=a x A \cdot A x a \sqsubseteq a A a \tag{24}
\end{equation*}
$$

and we conclude

$$
\begin{equation*}
(a)_{r}(a)_{l} \subseteq I a+I a^{2}+a A a=(a)_{(1,1)} \tag{25}
\end{equation*}
$$

Conversely, by condition (IV), it is obvious that

$$
\begin{equation*}
(a)_{(1,1)} \subseteq(a)_{r} \cap(a)_{t}=(a)_{r}(a)_{t} \tag{26}
\end{equation*}
$$

Thus (I) implies (V).
To prove that $(\mathrm{V}) \Rightarrow(\mathrm{I})$, suppose that the ring $A$ satisfies condition (V). Then we have

$$
\begin{equation*}
(a)_{(1,1)}=(a)_{r}(a)_{l} \tag{27}
\end{equation*}
$$

for any element $a$ in $A$. (27) implies

$$
\begin{equation*}
a \in(I a+a A)(I a+A a)=I a^{2}+a A a+a A^{2} a=I a^{2}+a A a \tag{28}
\end{equation*}
$$

In other words, there exists a rational integer $m$ and an element $b \in A$, such that

$$
\begin{equation*}
a=m a^{2}+a b a=a(m a+b a) . \tag{29}
\end{equation*}
$$

For the element $e=m a+b a$ we obtain $a=a e$ and $e^{2}=e$, whence

$$
a=a e^{2}=a(m a+b a)^{2}=a\left(m^{2} a^{2}+m a b a+m b a^{2}+b a b a\right) \in a A a .
$$

This implies (1).
It is easy to show that in case of regular rings we have

$$
\begin{equation*}
(a)_{r}(a)_{l}=a A a \text {, } \tag{30}
\end{equation*}
$$

therefore $(\mathrm{I}) \Leftrightarrow(\mathrm{VI})$.
$(\mathrm{I}) \Leftrightarrow(\mathrm{VII})$. This has been proved by J. LuH [15].
$(\mathrm{I}) \Rightarrow(\mathrm{VIII})$. This follows at once from a result of S. Lajos [10], Theorem 1, and from the above mentioned assertion of J. LuH.
(VIII $\Rightarrow(\mathrm{I})$. If $A$ is a ring satisfying condition (VIII), then it satisfies also (VII), which implies (I).

Therefore Theorem 2 is completely proved.
Theorem 3. The following fifteen conditions for an associative ring are pairwise equivalent:
(I) $A$ is strongly regular.
(II) $A$ is a two-sided ${ }^{2}$ ) regular ring.
(III) $A$ is a subcommutative ${ }^{3}$ ) regular ring.
(IV) $B^{2}=B$ for any bi-ideal $B$ of $A$.
(V) $\quad Q^{2}=Q$ for any quasi-ideal $Q$ of $A$.
(VI) $R L=L \cap R \subseteq L R$ for any left ideal $L$ and for any right ideal $R$ of $A$.
(VII) $L \cap R=L R$ for every left ideal $L$ and for every right ideal $R$ of $A$.
(VIII) $L_{1} \cap L_{2}=L_{1} L_{2}$ and $R_{1} \cap R_{2}=R_{1} R_{2}$ for any left ideals $L_{1}, L_{2}$ and for any right ideals $R_{1}, R_{2}$ of $A$.
(IX) $L \cap T=L T$ and $R \cap T=T R$ for every left ideal $L$, for every right ideal $R$, and for every two-sided ideal $T$ of $A$.
(X) $A$ is regular and it is a subdirect. sum of division rings.
(IX) $A$ is a regular ring with no non-zero nilpotent elements.
(XII) $L_{1} \cap L_{2}=L_{1} L_{2}$ for any two left ideals. of $A$.
(XIII) $R_{1} \cap R_{2}=R_{1} R_{2}$ for any two right ideals of $A$.
(XIV) $L \cap T=L T$ for any left ideal $L$ and for any two-sided ideal $T$ of $A$.
(XV) $R \cap T=T R$ for any right ideal $R$ and for any two-sided ideal $T$ of $A$.

Proof. (I) $\Leftrightarrow$ (II). This was proved in [14].
(II) $\Rightarrow$ (III). Assume that $A$ is a two-sided regular ring. Then every onesided (left or right) ideal of $A$ is a two-sided ideal in $A$, consequently we have

$$
\begin{equation*}
A x A \subseteq x A \text { and } A x A \subseteq A x \tag{31}
\end{equation*}
$$

The solvability of any equation $a y a=a(a \in A)$ implies $a \in a A$ and $a \in A a$, for every $a \in A$, therefore by (31)

$$
\begin{equation*}
A x \sqsubseteq x A \quad \text { and } \quad x A \sqsubseteq A x \tag{32}
\end{equation*}
$$

Thus we conclude that $x A=A x$ for every element $x$ in $A$. This exactly is the (twosided) subcommutativity of the regular ring $A$.
(III) $\Rightarrow$ (II). Suppose that $A$ is a (two-sided) subcommutative regular ring. Then every principal right ideal $(a)_{r}$ of $A$ can be generated by an idempotent element $e$ of $A$, that is

$$
\begin{equation*}
(a)_{r}=(e)_{r}=e A, \quad e^{2}=e \tag{33}
\end{equation*}
$$

[^1]From condition (III) and Theorem 2 we conclude

$$
\begin{equation*}
A(a)_{r}=A(e A)=e A^{2}=e A=(a)_{r} \tag{34}
\end{equation*}
$$

whence $(a)_{r}$ is a two-sided ideal. Consequently an arbitrary right ideal $R$ of $A$ is also a two-sided ideal of the ring $A$. Similarly it can be proved that every left ideal $L$ of $A$ is also a two-sided ideal in $A$. Thus we have proved that (II) $\Leftrightarrow$ (III).
$(\mathrm{I}) \Leftrightarrow(\mathrm{V})$. This follows from Theorem 2 of L. Kovács [6] and from authors' Theorem in [14].

Next we show that (IV) $\Leftrightarrow(\mathrm{V})$.
The implication (IV) $\Rightarrow(\mathrm{V})$ is evident. The converse of this statement is a consequence of the above mentioned result of L. Kovács, and Theorem 1 of S. Lajos [10].

Finally the equivalence of the conditions (VI)-(XV) with each other and with condition (I) was proved [14].

Thus Theorem 3 is proved.
It is known that every regular ring is semisimple in the sense of N. Jacobson. The following assertion characterizes the semisimple rings $A$ in the class of rings with property:
(*) The lattice of all right ideals of $A$ is a chain ${ }^{4}$ ).
Proposition 8. For a ring $A$ with property (*) the following conditions are equivalent:
(I) $A$ is semisimple.
(II) $A$ is regular.
(III) $A$ is strongly regular.
(IV) $A$ is direct sum of division rings.
(V) $A$ is a division ring.

Proof. In what follows we assume that the ring $A$ satisfies the condition (*). It is easy to see, that Proposition 8 will be proved if we demonstrate the equivalence of (I) and (V), because every class ( $N$ ) of rings in Proposition 8 contains the class of rings with property $(N+I)$; where $N=\mathrm{I}$, II, III, IV.

Suppose that $A$ is a ring with radical $J=0$. Then the intersection of the modular maximal right ideals $R_{\lambda}(\lambda \in \Lambda)$ of $A$ is ( 0 ) by $N$. Jacobson [5], Chapter I. In virtue of property (*) and of the maximality of the right ideal $R_{\lambda}$ we conclude $R_{\lambda}=0$, whence $A$ contains no non-trivial right ideals. Therefore $A$ is a division ring.

Proposition 8 is completely proved.
Remark 6. A subclass of the class of rings with property (*) was earlier discussed by E. C. Posner [17]. Moreover, L. A. Skornjakov [24] has obtained some results concerning rings with the left-right dual of property (*).

[^2]Remark 7. Let $A$ be the ring of all matrices of type $2 \times 2$ over the field with two elements. Then $A$ is a ring with sixteen elements having the property that $B A B=B$ holds for every bi-ideal $B$ of $A$. Moreover, let $B_{0}$ be the bi-ideal generated by the element

$$
\left[\begin{array}{ll}
0 & 1 \\
0 & 0
\end{array}\right] .
$$

Then we obviously have $B_{0}^{2}=0 \neq B_{0}$. Evidently $A$ is regular, but not strongly regular and $A$ does not satisfy condition (*).
