

## On $n$ -permutable equational classes

By E. T. SCHMIDT in Budapest

The product  $\Theta \circ \Phi$  of two congruences  $\Theta, \Phi$  of an algebra  $A$  is defined by the following rule:  $a \equiv b(\Theta \circ \Phi)$  if and only if  $c \in A$  exists such that  $a \equiv c(\Theta)$  and  $c \equiv b(\Phi)$ . Two congruences  $\Theta_1$  and  $\Theta_2$  are  $n$ -permutable if and only if  $\Theta_1 \circ \Theta_2 \circ \Theta_1 \circ \Theta_2 \circ \dots = \Theta_2 \circ \Theta_1 \circ \Theta_2 \circ \Theta_1 \circ \dots$ , where on both sides there are  $n$  factors. An algebra  $A$  is  $n$ -permutable if every two congruences in  $A$  are  $n$ -permutable. We define an equational class to be  $n$ -permutable if every algebra of this class is  $n$ -permutable. It is well known, that an  $n$ -permutable equational class is  $(n+1)$ -permutable. In [1] G. GRÄTZER asks for examples of equational classes which show that  $n$ -permutability and  $(n+1)$ -permutability are not equivalent<sup>1)</sup>. In this note we give an example with this property.

**Theorem.** *For every natural number  $n > 2$  there exists an  $(n+1)$ -permutable equational class  $\mathcal{K}_n$  which is not  $n$ -permutable.*

**Proof.** Let  $n$  be a natural number. An  $n$ -Boolean algebra

$$\mathcal{B} = (\mathcal{B}; \vee, \wedge, f_1(x), \dots, f_n(x), o_0, o_1, \dots, o_n)$$

is an algebra with two binary operations  $\vee, \wedge$ ,  $n$  unary operations  $f_1(x), \dots, f_n(x)$  and  $n+1$  nullary operations  $o_0, o_1, \dots, o_n$ , such that the following conditions are satisfied:

1.  $(\mathcal{B}; \vee, \wedge)$  is a distributive lattice;
2.  $x \vee o_n = o_n$ ;  $x \vee o_0 = x$  for all  $x \in \mathcal{B}$ ;
3.  $[(x \vee o_{i-1}) \wedge o_i] \vee f_i(x) = o_i$ ;  $[(x \vee o_{i-1}) \wedge o_i] \wedge f_i(x) = o_{i-1}$ .

The class of all  $n$ -Boolean algebras is denoted by  $\mathcal{K}_n$ . If  $o_{i-1} \leq x \leq o_i$  then  $f_i(x)$  is the relative complement from  $x$  in  $[o_{i-1}, o_i]$ , i.e. this interval is a Boolean lattice. A 1-Boolean algebra is a Boolean algebra. A finite chain  $\mathcal{C}_n$  of  $n+1$  elements is

<sup>1)</sup> For  $n=2$  A. MITSCHKE [2] has solved this problem.

an  $n$ -Boolean algebra, if we take its elements as nullary operations:  $o_0 < o_1 < o_2 < \dots < o_n$  ( $o_i \in \mathcal{C}_n$ ), and  $f_i(x) = o_i$  if  $x < o_i$ ,  $f_i(x) = o_{i-1}$  if  $x \geq o_i$ . The congruences of  $\mathcal{C}_n$  are the lattice-congruences, i.e.  $\mathcal{C}_n$  is not  $n$ -permutable. This shows that  $\mathcal{K}_n$  is not  $n$ -permutable.

Let  $B$  denote an arbitrary  $n$ -Boolean algebra and  $x, y \in B$ ,  $x > y$ . Set  $a_i = (o_i \wedge x) \vee y$ . (Then is  $a_0 = y$ ,  $a_n = x$ .) If  $\Theta_1$  and  $\Theta_2$  are arbitrary congruences from  $B$ , such that  $x \equiv y$  ( $\Theta_1 \vee \Theta_2$ ), then  $a_{i-1} \equiv a_i$  ( $\Theta_1 \vee \Theta_2$ ) ( $i=1, 2, \dots, n$ ). The interval  $[a_{i-1}, a_i]$  is projective to a subinterval of  $[o_{i-1}, o_i]$ , i.e.  $[a_{i-1}, a_i]$  is a Boolean lattice. Every Boolean lattice is 2-permutable and so for every  $i$  ( $i=1, 2, \dots, n$ ) there exists a  $t_i \in [a_{i-1}, a_i]$  such that

$$a_{i-1} \equiv t_i (\Theta_1) \quad i \text{ odd}, \quad a_{i-1} \equiv t_i (\Theta_2) \quad i \text{ even}, \quad a_i \equiv t_i (\Theta_1) \quad i \text{ even}, \quad a_i \equiv t_i (\Theta_2) \quad i \text{ odd}.$$

We have therefore between  $x, y$  a chain  $y_0 = a_0 = y$ ,  $y_1 = t_1, y_2 = t_2, \dots, y_n = x = a_n$  with  $n+1$  elements, such that  $y_{i-1} \equiv y_i (\Theta_1)$  if  $i$  even and  $y_{i-1} \equiv y_i (\Theta_2)$  if  $i$  odd.  $\mathcal{K}_n$  is therefore  $(n+1)$ -permutable.

Remark. An equational class is  $(n+1)$ -permutable if and only if there exists  $(n+2)$ -ary algebraic operations  $p_0, \dots, p_{n+1}$  satisfying the following identities (see [3]):

$$p_0(x_0, \dots, x_{n+1}) = x_0, \quad p_{i-1}(x_0, x_0, x_2, x_2, \dots) = p_i(x_0, x_0, x_2, x_2, \dots) \quad (i \text{ even}),$$

$$p_{i-1}(x_0, x_1, x_1, x_3, x_3, \dots) = p_i(x_0, x_1, x_1, x_3, x_3, \dots) \quad (i \text{ odd}),$$

$$p_{n+1}(x_0, \dots, x_{n+1}) = x_{n+1}.$$

A. MITSCHKE and H. WERNER have considered for the class  $\mathcal{K}_n$  the algebraic operations:

$$p_i(x_0, x_1, \dots, x_{n+1}) = (x_i \wedge f_{n+1-i}(x_{i+1}) \vee x_{i+2}) \vee (x_{i+2} \wedge (f_i(x_{i+1}) \vee x_i))$$

which show that  $\mathcal{K}_n$  is  $(n+1)$ -permutable.
