**Behavioural Ecology of New Zealand Invasive Rodents (*Rattus norvegicus*
and *Mus musculus*): Implications for Rodent Control**

A thesis presented in partial fulfilment of the requirements for the degree of

Doctor of Philosophy in Ecology

at Massey University, Auckland, New Zealand

Idan Shapira

2013

FRONTISPIECE

Walter: And let's also not forget... let's not forget, Dude... that keeping wildlife, an amphibious rodent, for uh, domestic, you know, within the city... that isn't legal either.

Dude: What're you, a fucking park ranger now?

(Ethan and Joel Coen, "The Big Lebowski")

ABSTRACT

Biological invasions are natural phenomena that have occurred throughout the natural history of earth. The highly negative context of the term biological invasion is associated with the fact that many modern invasive processes are anthropogenically driven. Indeed, human affiliated invasions are among the primary drivers of the current biodiversity crises. Murid rodents (Rodentia: Muridea) of the genus *Rattus* and *Mus* have become among the worst vertebrate invasive species and apart from man are the most widespread mammals on earth. Invasive rodents have severe and negative effects on human health, agricultural systems, and natural environments. The practice of rodent control is extensive and substantial attempts are made to decrease rodents' severe impacts on the environment. However, although these attempts are largely successful, there are still issues in the control of invasive rodents and new methodologies, whether at a macro or micro scale are actively pursued.

Behavioural conservation attempts to understand and improve conservation processes and practices through the study of animal behaviour. Indeed, it is becoming increasingly apparent that the behaviour of animals can be a strong tool for conservation. The control of invasive species has the goal of reducing predatory or competition pressure on species of conservation concern and advocates for behavioural conservation acknowledge the importance of behavioural studies of invasive species that can directly benefit or inform control measures. In this thesis, I explore several aspects of behavioural ecology in the Norway rat *R. norvegicus* and the house mouse, *M. musculus*, with the overarching aim of informing and improving rodent control.

I conducted a series of laboratory and field experiments focused on rodent behaviour and pest control. 1) I tested whether laboratory rats can act as effective lures for wild Norway rats and hence overcome the problem of rats avoiding food baits. This field experiment was based on the highly social behaviour exhibited by this species. I found that live traps containing live lures were significantly more effective than those with food baits at capturing wild Norway rats. In a second series of tests, I found that live lures were more efficient than food baits at attracting rats to kill traps. A study of radio-collared rats released onto a rat-free island produced inconclusive but promising results on the potential of live lures to be used to control incursions. I suggest that the use of laboratory rats as lures should be considered as an additional tool for use in future pest control management plans for invasive Norway rats. 2) I used Y-maze laboratory experiments to examine the attractiveness of urine from mice fed high and low protein diets to male and female wild mice, whether the protein content of the diet of mice affected their response and the strength of attraction of wild mice towards wild and laboratory live lure conspecifics of the opposite sex. I found that mice preferred to spend more time close to urine from donors that had eaten a high protein diet, that mouse strain did not affect conspecific attraction and that males were more active than females toward the urine of the opposite sex. These results may have implications for improving mouse capture and control. 3) I assessed the impacts of mammalian odours (specific direct cues of predation or competition) and illumination intensity (a general indirect cue of predation) on the foraging of free-ranging mice that are naïve to mammalian predators, using feeding trials in the field. Here I found that phases of the moon, but not odour, had significant effects on mouse foraging behaviour. I suggest that repeating the study over multiple lunar cycles is required to confirm this influence and, if confirmed, recommend coordinating management

efforts according to the phases of the moon to improve mouse bait take and reduce bait wastage. 4) I tested for the responses of rat-naïve mice to scent cues from rats, which are competitors and potential predators in laboratory experiments, in a Y-maze apparatus. Mice behaviours revealed unexpected differences in male and female responses to rat scent. Male mice showed preference to control over rat scented food trays, while females were indifference in their preferation or even preferred rat scented food trays over control ones. These sex-based differences can suggest that males and females might be under different evolutionary pressures in regard to novel scents. 5) I looked at macronutrient selection in wild caught mice, under controlled laboratory conditions. I found that mice consumed more of diets with a high carbohydrate/protein ratio, but were highly generalist and opportunistic feeders, in general prioritising energy over macronutrients. These results demonstrate that the pattern of macronutrient selection is sensitive to ecological circumstances, and associates an opportunistic strategy with successful invasion by a small mammal in a temperate environment.

The understanding and improvement of conservation practices directly through the study of animal behavioural processes is an emerging and rapidly growing science, but relatively little attention is given to the benefits that we can draw from incorporating and understanding of invasive species behaviour into their control. To maintain an effective and continuous control of invasive species, managers need comprehensive knowledge of the behaviour of the species they target. This can be achieved only through targeted behavioural research of invasive species that is directed at improving pest control. In this thesis I have attempted to do just this.

ACKNOWLEDGMENTS

“One of the symptoms of an approaching nervous breakdown is the belief that one's work is terribly important”.

(Bertrand Russell)

I had my semi nervous breakdown at the end of the first year of my PhD. Luckily, my children Omer and Alma, who were born during this PhD have knocked me back to my senses. This thesis is dedicated to them with love.

First and foremost I would like to thank my supervisors. To Dianne Brunton, the principle supervisor, who told me to come over from Israel after one email correspondence, and always made sure I had everything I needed. Hopefully she doesn't regret placing my desk just next to her office, an act that resulted in countless knocks upon her door... Nonetheless, all my visits were met with a smile! To the one and only Uri Shanas, who after supervising my MSc in Israel, (understandably) had to send me to the most far away place possible, but still provided professional and emotional support. And to David Raubenheimer, who was last to jump aboard but nevertheless delivered significant scientific perspectives and new research directions. Not to mention the mutual respect we share for the Dude... I have learned much from you all!

During the four years of this immense project, many people were involved in my research and in my life. Their contribution varies from crucial help to a friendly word. Here I wish to

thank all these people, named in a random order. Shauna Billie, Michael Anderson, Mark Delaney, Kevin Parker, Marleen Barling, Jenny Laycock, Achyut Aryal, Alice Tait, Elizabeth Laman-Trip, Andy Warneford, Debbie Chesterfield, Brigitte Kreigenhofer, Anne Sophie Boyer, Birgit Ziesemann, Cheeho Wong, Chris Wedding, David Gudex-Cross, Dylan van Winkel, Emmanuelle Martinez, Gabriel Machovsky-Capusca, Jennifer Ricket, James Dale and Laura Redfern, Jo Peace, Jurgen Kolb, Luis Ortiz Cathedral, Karen Stockin, Manuella Barry, Ben Barr, Mark Seabrook-Davidson, Anna Gsell, Monique Van Rensberg, Sarah Dwyer, Sarah Wells, Ravit and Reuben Hass, Natalie and Ra'anan Neuman, Shane and Moses Sheleg, Gavin Martin, Anna Drijver and Terry Chee, Joshua Thoresen, Craig Knapp, Rebecca Greenop, Rodney Bowden, Christophe Amiot, James Russell, Ian Fraser, Tineke Joustra, Samantha Kudwe, Adrian Peterson, Megan Young, Miriam Ludbrook, Kelsey Nichols, Frederica Jordan, John Innes, Susan Alberts, Keith Hawks, John Cope, Jim & Eddie (Massey Albany facilities), Pablo Stevenson, Tony Lawson, Cheridan Mathers, Fiona McKenzie, Virginia Moreno, John Steenman.

Amorita Petzer from the University of Auckland kindly provided most of the laboratory animals, always willingly and with a smile.

The following organizations have been extremely helpful and their cooperation and support is highly appreciated. Auckland Council provided permits to work on council land as well as help with field assistance and funds. I am especially grateful to Matt Maitland, Steve Burgess, Bruce Harvey, Tim Lovegrove and Maurice Puckett. The Department of Conservation (DOC) provided permits to work in their reserves, technical support and aid in

running experiments. Special thanks should go to Phil Brown, Fin Buchanan and Pie (the super rat dog) for their grate support - you guys rock! I also thank all the DOC Auckland area office Skippers, Tawharanui Open Sanctuary Society (TOSSI) and Shakespear Open Sanctuary Society (SOSSI), Forest and Bird, especially John Staniland, Honda Marine for contributing a research boat, and of course Massey University for supporting this project.

I thank my good friends and broader family in Israel for moral support: Avia and Amos Nevo, Ynon, Nitzan and Alon Nevo, Tamar and Elisha Shapira, Haim Dovrovni, Neta and Einat Shapira, Orna and Gili Salomon, Greg Golomb, Nurit and Gilad Ben-Ziv, Shani and Tomer Lavi, Tsur Kramer, Batya Reznick, Noam Evron, Gal and Shacham Mittler, Inbar and Yali Dagan, Elya and Alon Lotan, Ohad Fleiderman, Gadi Katzir, Ran Dreilich, Ayelet Ben-Nahum, Amir (Chatuka) Arnon, and Idit Brill.

I thank with love my close family, my brothers and their families, Liron, Sigalit and Carmel, Gal and Matan Shapira, Oran Shapira, Delphine Vann and Scott Roe Vann. Special thanks should go to my parents Shoshana and Gideon Shapira - I couldn't have accomplished this PhD without your support!

Thanks should also go to my partner's close family, bobe Berta Waitzman, brothers David Lischinky and Doron and Lital Lischinsky and a huge muchas gracias to my partner's parents Sofia and Julio Lischinsky who have greatly supported our family in New Zealand.

I wish to thank my partner Dana Lischinsky, who travelled with me all the way to the far end of the world, and supported me in more than one way throughout many good times as well as numerous hard moments. I love you very much!

Special thanks should go to Ed Minot, Kay Clapperton and Peter Banks for reviewing the thesis and for making usefull comments that have improved the outcome of the thesis greatly.

I would like to further dedicate this PhD to my grandmother Zehava Teper (passed away 2013), my aunt Chava Dovrovni (passed away 2011) and my friend Einav Brill (passed away 2011). My they rest in peace.
