(Received 24 April 2014)

A high-power high-efficiency laser power transmission system at 100 m based on an optimized multi-cell GaAs converter capable of supplying 9.7 W of electricity is demonstrated. An  $I$ - $V$  testing system integrated with a data acquisition circuit and an analysis software is designed to measure the efficiency and the  $I$ - $V$  characteristics of the laser power converter (LPC). The dependencies of the converter's efficiency with respect to wavelength, laser intensity and temperature are analyzed. A diode laser with 793 nm of wavelength and 24 W of power is used to test the LPC and the software. The maximum efficiency of the LPC is 48.4% at an input laser power of 8 W at room temperature. When the input laser power is 24 W (laser intensity of 60000 W/m<sup>2</sup>), the efficiency is 40.4% and the output voltage is 4 V. The overall efficiency from electricity to electricity is 11.6%.

DOI: 10.1088/0256-307X/31/10/104203

Laser power transmission provides a powering link insensitive to electromagnetic noise and electrically isolated between the ends.<sup>[1,2]</sup> Laser power can be effectively converted into electricity by appropriate photovoltaic (PV) cells based on semiconductor heterostructure. Many experiments involving laser power transmission technology have been reported. In 1997, Yugami *et al.* tested a GaAs cell (4 cm<sup>2</sup> area) with a laser at a wavelength of 808 nm and power of 1 W. The laser power intensity was 2500 W/m<sup>2</sup>. The conversion efficiency of the GaAs cell they obtained was 51%, while the fill factor was not considered.<sup>[3]</sup> In 2002, Steinsiek *et al.* transmitted a 5 W laser ( $\lambda = 532$  nm) to drive a small rover vehicle over a distance of 280 m. The rover was equipped with InGaP cells (18.9 cm<sup>2</sup> area); the efficiency of the InGaP cells was 40% under an intensity of 2648 W/m<sup>2</sup>.<sup>[4]</sup> However, few data have been published on the performance of converters at higher laser power intensity. Due to the fact that when a PV cell is illuminated under high laser intensity, the thermal effect will cause an increase of series resistance of the cell,<sup>[5-7]</sup> therefore, the efficiency of a PV cell drops with the higher laser intensity. In 2012, Mukherjee *et al.* demonstrated an InGaAs/InP converter (0.25 cm<sup>2</sup> area) illuminated by a laser ( $\lambda = 1.55$   $\mu$ m) with a conversion efficiency of 44.6% under an illumination intensity of 1000 W/m<sup>2</sup>; however, the efficiency dropped to 40.6% when the illumination intensity was boosted to 2370 W/m<sup>2</sup>.<sup>[8]</sup>

In some applications, converters working at high laser power and intensity are more desirable to reduce the volume and cost of whole systems. Therefore, one of the research topics in this area is how to

improve the conversion efficiency from laser power to electricity at high laser illuminating power and intensity. In this Letter, a specially designed optimized multi-cell GaAs converter working at high laser intensity is presented. We demonstrate a high power space laser transmission system capable of supplying 9.7 W electricity. A 793 nm diode laser at a distance of 100 m is used to illuminate the optimized multi-cell GaAs converter, the maximum efficiency of the LPC from laser power to electricity is 48.4% at an input laser power of 8 W (20000 W/m<sup>2</sup>) at room temperature. Moreover, the efficiency is 40.4% when the laser power is 24 W (60000 W/m<sup>2</sup>). The overall efficiency (the product of the laser wall-plug efficiency, the optical system's transmission efficiency and the LPC conversion efficiency) from electricity to electricity is 11.6%. Compared with the previous works,<sup>[9]</sup> the transmission system is improved dramatically with the longer transmission distance, higher laser power and greater electricity supply. A newly designed  $I$ - $V$  testing system is used to measure the performance of the GaAs converter.

A laser power transmission system with parameters shown in Fig. 1 is designed to transmit a laser to an LPC. A fiber coupled laser diode at 793 nm is selected. Its wavelength is close to the absorption peak of the GaAs cell. A telescope is installed on a three-dimensional electric motor platform for automatically tracking the LPC, as shown in Fig. 2(a). To reduce chromatic aberration, an aspherical lens is used as the collimating lens. Its parameters are optimized with the ZEMAX software. A receiving lens is used to focus the laser beam on to the LPC, as shown in

Fig. 2(b). We measured the laser power at the position of the LPC; the transmittances of the optics at different emitted laser powers are presented in Table 1. An  $I$ - $V$  test system is integrated with a data acquisition circuit, analysis software and a display.

**Fig. 1.** Schematic diagram of the laser power transmission at 100 m and the data analysis system.

**Fig. 2.** Photographs of the automatic tracking telescope system and receiving system.

**Table 1.** Transmittance of the 100 m transmission optical system.

Emitted laser power (W)	11.80	25.00	39.80	52.70
Received laser power (W)	10.90	24.00	38.30	51.40
Transmission efficiency (%)	92.3	96	96.2	97.5

To make an electron free in the material from its covalent bond, the energy of the photon needs to be higher than the ‘band-gap energy’ of the material. Band-gap energy  $E_g$  is inversely proportional to the cutoff wavelength  $\lambda_c$ ,

$$\lambda_c = 1240/E_g, \quad (1)$$

where  $E_g$  is in electron volts and  $\lambda_c$  is in nanometers.

The band-gap energy  $E_g$  can be commonly expressed in terms of  $\alpha$  and  $\beta$  coefficients of the Varshni equation

$$E_g(T) = E_g(0) - \frac{\alpha T^2}{T + \beta}, \quad (2)$$

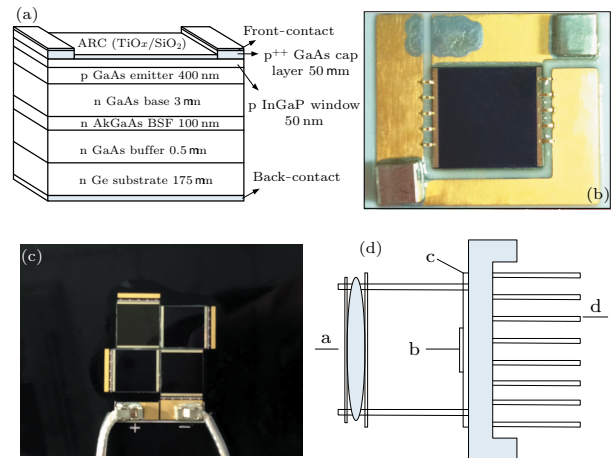

where  $E_g(0)$  is the band-gap energy at 0 K,  $\alpha$  is in electron volts per degree Kelvin, and  $\beta$  is proportional to the Debye temperature (in Kelvin). For GaAs  $E_g(0) = 1.517$ ,  $\alpha = 5.5$ ,  $\beta = 225$ .<sup>[10]</sup> Substitute these values into Eq. (2), we can calculate the band-gap energy at different temperatures. At room temperature 298 K,  $E_g$  is 1.424 eV. According to Eq. (1), the cutoff wavelength is calculated to be  $\lambda_c = 870$  nm.

The spot diameter of the transmitted laser beam is given by

$$\phi_{spot} = 2.44\lambda D/\phi', \quad (3)$$

where  $\phi'$  is the diameter of the optics for collimation, and  $D$  is the transmission distance.

Figure 3(a) shows the single-junction GaAs structure on a Germanium substrate. The thickness of each layer was optimized for working at high laser intensity. It consists of: the n-Ge substrate (175  $\mu\text{m}$ ), n-GaAs buffer (0.5  $\mu\text{m}$ ), n-AlGaAs BSF (100 nm), n-GaAs base (3  $\mu\text{m}$ ), p-GaAs emitter (400 nm), p-InGaP window (50 nm), and p<sup>++</sup>-GaAs cap layer (0.5  $\mu\text{m}$ ). The GaAs cell has a photosensitive surface area of 10  $\times$  10 mm<sup>2</sup>. This structure is optimized for operation at more than 50000 W/m<sup>2</sup> laser intensity. The cell’s surface is coated with antireflective coating (TiO<sub>x</sub>/SiO<sub>2</sub>) for the 400–900 nm wavelength. Figure 3(b) is the top view of a single cell mounted on a copper substrate with n-side down. Four such cells are connected in a series from a monolithic block, as shown in Fig. 3(c). The photosensitive surface area is 400 mm<sup>2</sup>. Here 1 mm gaps remained between cells for electrode connection. Figure 3(d) shows the LPC consisting of an optics, a monolithic block, a thermoelectric cooler and a heat sink.<sup>[11]</sup>

**Fig. 3.** (a) A GaAs cell fabricated on a Ge substrate. (b) Top view of the prototype of a single GaAs cell with a photosensitive surface area of 10  $\times$  10 mm<sup>2</sup>. (c) Optimized multi-cell GaAs cells with a photosensitive surface area of 20  $\times$  20 mm<sup>2</sup>. (d) Schematic diagram of the laser power converter: a–optics, b–monolithic block, c–thermoelectric cooler, and d–heat sink.

Under high intensity laser illumination, the process of measuring a GaAs cell’s output characteristics is critical due to the fact that a GaAs cell has low open-circuit voltage and high short-circuit current. Presently, the methods for measuring the  $I$ - $V$  curve can be divided into passive load and active load. Passive load can be resistive or capacitive. With a capacitive load, one can reach almost the short circuit current, the only limit is the internal series resistance.

This makes using a capacitive load a better solution for measuring  $I$ - $V$  characteristics. Figure 4 shows the schematic diagram of the  $I$ - $V$  testing circuit with a capacitive load. Test points 1 and 2 are connected to an oscilloscope with two channels to measure the current and voltage slopes respectively. The value of the shunt resistor must be small and precise enough to meet the load capacity of the cell. For testing a single cell, we choose  $0.1\ \Omega$  value of the shunt resistor, its precision is 1%. For testing the optimized multi-cell GaAs cells, another resistor with a value of  $1.5\ \Omega$  is used. The capacitor must be large enough to offer a long charging time. The value of the capacitor is  $470\ \mu\text{F}$  (KEMET, P/N: T520D477M004ATE010), the parasite equivalent series resistance (ESR) is  $10\ \text{m}\Omega$ . Note that the ESR of each capacitor can greatly affect the testing data due to the drop of voltage on it, thus several capacitors are connected in parallel to reduce the ESR. The  $I$ - $V$  data are obtained by an oscilloscope and transferred to a computer with an analysis software designed with Labview. The software integrates functions of the  $I$ - $V$  curve record, max power point finding and fill factor calculation.

Fig. 4. Schematic diagram of the  $I$ - $V$  test system with capacitive load.

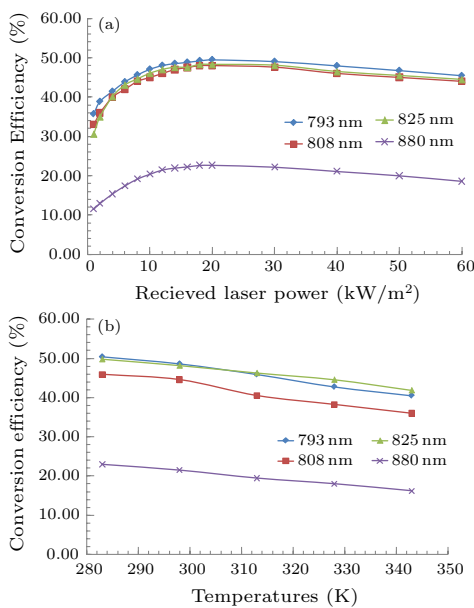

Fig. 5. GaAs response with respect to wavelengths, laser intensity and temperatures.

A single GaAs cell, shown in Fig. 2(b), is tested in-

doors to analyze the dependencies of the single GaAs efficiency with respect to wavelength, laser intensity and temperature. We tested laser diodes at wavelengths of 793 nm, 808 nm, 825 nm and 880 nm. Figure 5(a) shows the dependency of efficiency with respect to laser intensity; it is shown that, at low intensity, the efficiency increases slightly with the laser intensity and gradually becomes saturated, when the laser intensity is higher than  $20000\ \text{W}/\text{m}^2$ , the efficiency declines due to the increase of the series resistance of the cell; the highest efficiency of 49.7% is obtained when the laser intensity is  $20000\ \text{W}/\text{m}^2$  at  $\lambda = 793\ \text{nm}$ . To the best of our knowledge, this is the highest conversion efficiency obtained at such high laser intensity. The efficiency is much lower at  $\lambda = 880\ \text{nm}$  due to the fact that the photon energy is lower than the GaAs material band gap. The efficiency decreases with the increase of temperature, as shown in Fig. 5(b).

Fig. 6. The  $I$ - $V$  and power-voltage curves.

As shown in Fig. 5(b), the conversion efficiency decreases with the increase of temperature. The dependency of the efficiency  $\eta$  to temperature  $T$  is expressed by

$$\eta(T) = \eta(298\ \text{K}) + \frac{\eta(298\ \text{K})(T - 298\ \text{K})}{\eta} \frac{d\eta}{dT}, \quad (4)$$

where  $(d\eta/dT)/\eta$  is the normalized temperature coefficient of the efficiency. Note that  $\eta$  is related to the cell's maximum power  $P_m$ . Clearly,  $(d\eta/dT)/\eta = (dP_m/dT)/P_m$ . The temperature coefficient is determined by the variation of open voltage, short current and fill factor using the relation

$$\frac{1}{P_m} \frac{dP_m}{dT} = \frac{1}{I_{sc}} \frac{dI_{sc}}{dT} + \frac{1}{U_{oc}} \frac{dU_{oc}}{dT} + \frac{1}{FF} \frac{dFF}{dT}, \quad (5)$$

where  $P_m$  is the cell's maximum power,  $I_{sc}$  is the short circuit current,  $U_{oc}$  is the open circuit voltage,

and FF is the fill factor of the cell. For monochromatic illumination, the change in short circuit current  $I_{sc}$  and FF is negligible. Thus the temperature efficiency coefficient is mainly determined by the variation of open circuit voltage  $U_{oc}$ . Here  $1/\eta(d\eta/dT) = 1/U_{oc}(dU_{oc}/dT)$ , the temperature coefficient of open voltage

$$\frac{dU_{oc}}{dT} = \frac{U_{oc} - E_g(T)}{T} - \frac{3k}{q} - \frac{\alpha T(T + 2\beta)}{(T + \beta)^2}. \quad (6)$$

It is observed that the temperature coefficient of open voltage is negative.<sup>[12]</sup> Combining with Eq. (4), as the temperature coefficient is negative, it is seen that the efficiency decreases with the increase of temperature.

Figure 6 shows the GaAs cell response curve illuminated at  $\lambda = 793$  nm laser intensity of  $60000$  W/m<sup>2</sup> with different temperatures.

Figure 6(a) shows the  $I$ - $V$  curves at the temperatures of 283 K, 298 K, 313 K, and 328 K. Here  $U_{oc}$  increases logarithmically with the short circuit current  $I_{sc}$ , and  $U_{oc}$  decreases with the increase of temperature.<sup>[13–15]</sup>

**Fig. 7.** The  $I$ - $V$  curve and efficiency-voltage curve under 20 W and 24 W laser illumination for the optimized multi-cell LPC.

Graphically, the fill factor is a measure of the ‘squareness’ of the  $I$ - $V$  curve and is the area of the largest rectangle that fits in the  $I$ - $V$  curve. The fill factor is also defined as the ratio of maximum obtainable power to the product of the open-circuit voltage  $U_{oc}$  and short-circuits current  $I_{sc}$ .<sup>[16]</sup> The expression is

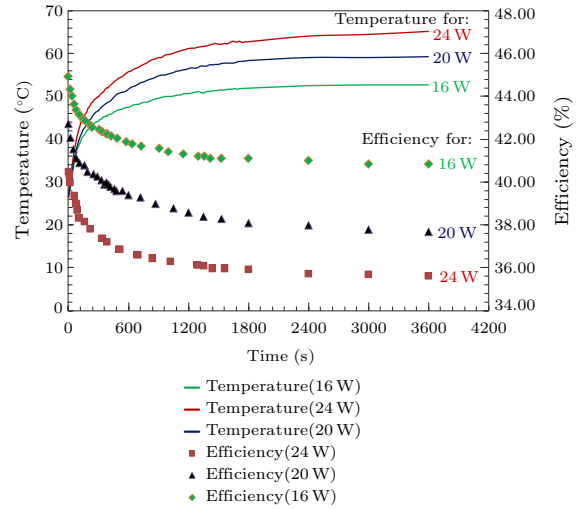

$$FF = U_{max}I_{max}/U_{oc}I_{sc}, \quad (7)$$

where  $U_{max}$  and  $I_{max}$  are the voltage and current at the maximum power point. The maximum power point is displayed as the vertex of the power-voltage

curve in Fig. 6(b), which reveals that the maximum power descends with the increase of temperature. Apparently, it is seen that the cell fill factor decreases with the increase of temperature.

The LPC with optimized multi-cell GaAs cells is tested in a 100 m laser power transmission outdoor experiment. Figure 7 shows the LPC response curve illuminated by laser powers of 20 W (a) and 24 W (b) at different temperatures. Note that the curves with marks are the efficiency-voltage curves, the others are the  $I$ - $V$  curves. Apparently, both the cell fill factor and the open circuit voltage decrease with the increase of temperature.

In the case of natural cooling, where the thermoelectric cooler of the LPC is switched off, we measure the dependencies of the temperature and efficiency of the LPC with respect to time. The initial environmental temperature is 26.4°C. Figure 8 shows the temperature increases logarithmically over time, while the efficiency decreases rapidly after 5 min exposure. After 1 h, the temperatures (efficiency) stabilize at 65.0°C (35.6%), 59.3°C (37.7%) and 52.7°C (40.9%) when the LPC is illuminated at laser powers of 24 W, 20 W and 16 W, respectively.

**Fig. 8.** Temperature and efficiency versus time.

When the temperature is fixed at 25°C, the LPC conversion efficiencies illuminated at different laser powers are shown in Table 2. The LPC is capable of supplying 9.7 W of electricity at 24 W laser illumination with a high efficiency of 40.4%.

To analyze the overall efficiency of the laser power transmission system, the temperature is fixed at room temperature 298 K. The cell’s maximum power is 9.7 W. The voltage is 4 V and the current is 2.43 A with FF of 80%. The laser wall-plug efficiency is 30% measured at an emitted laser power of 25 W. The test transmittance of the optical system is 96% (shown in Table 1) for a 793 nm laser. The atmospheric transmission loss can be ignored due to the relatively short

transmission distance. The received laser power measured at the position of cell is 24 W. Here the data of the energy used to cool the cell is not included. In result, when the laser intensity is  $60000 \text{ W/m}^2$  and the

GaAs optical-electrical conversion efficiency is 40.4%, the overall efficiency (the product of the laser wall-plug efficiency, the optical system's transmission efficiency and LPC conversion efficiency) is 11.6%.

**Table 2.** LPC conversion efficiency at different laser powers (25°C).

Laser power (W)	2	4	8	12	16	20	24
Efficiency (%)	35.0	44.5	48.4	47.0	44.9	42.7	40.4

In summary, a high power laser transmission system at a distance of 100 m is demonstrated. An LPC with an optimized multi-cell GaAs converter capable of supplying 9.7 W of electricity at 24 W laser illumination with a high efficiency of 40.4% is fabricated. The overall efficiency from electricity to electricity is 11.6%. The dependencies of the converter's efficiency with respect to wavelength, laser power and temperature are measured and analyzed. Compared with the previous work in laser power transmission technology, we obtain a relatively high efficiency under high laser power and intensity. Such a laser power transmission system could prove to be extremely useful as a future power source, specifically in regions and targets where conventional energy delivery systems are disabled.

The authors thank the group of Shi Dele in the Shandong Institute of Aerospace Electronics for the design of the automatic tracking mechanical platform.

**CROSS-DISCIPLINARY PHYSICS AND RELATED AREAS OF SCIENCE AND TECHNOLOGY**

- 108401 A C-Band Internally-Matched High Efficiency GaN Power Amplifier**  
MA Xiao-Hua, WEI Jia-Xing, CAO Meng-Yi, LU Yang, ZHAO Bo-Chao, DONG Liang, WANG Yi, HAO Yue
- 108501 High-Pressure Water-Vapor Annealing for Enhancement of a-Si:H Film Passivation of Silicon Surface**  
GUO Chun-Lin, WANG Lei, ZHANG Yan-Rong, ZHOU Hai-Feng, LIANG Feng, YANG Zhen-Hui, YANG De-Ren
- 108502 Optical Performance of N-Face AlGaIn Ultraviolet Light Emitting Diodes**  
YU Hong-Ping, LI Shi-Bin, ZHANG Peng, WU Shuang-Hong, WEI Xiong-Bang, WU Zhi-Ming, CHEN Zhi
- 108503 High Performance Long Wavelength Superlattice Photodetectors Based on Be Doped Absorber Region**  
ZHOU Yi, CHEN Jian-Xin, XU Zhi-Cheng, WANG Fang-Fang, XU Qing-Qing, XU Jia-Jia, BAI Zhi-Zhong, JIN Chuan, HE Li
- 108504 Non-Volatile Threshold Adaptive Transistors with Embedded RRAM**  
DEND Ning, JIA Hong-Yang, WU Wei, WU Hua-Qiang
- 108505 Junctionless Coplanar-Gate Oxide-Based Thin-Film Transistors Gated by Al<sub>2</sub>O<sub>3</sub> Proton Conducting Films on Paper Substrates**  
WU Guo-Dong, ZHANG Jin, WAN Xiang
