15 Abstract

16 Vocal imitation is a hallmark of human spoken language, which, along with other advanced
17 cognitive skills, has fuelled the evolution of human culture. Comparative evidence has revealed that
18 although the ability to copy sounds from conspecifics is mostly uniquely human among primates, a
19 few distantly related taxa of birds and mammals have also independently evolved this capacity.
20 Remarkably, field observations of killer whales have documented the existence of group-
21 differentiated vocal dialects that are often referred to as traditions or cultures and are hypothesized
22 to be acquired non-genetically. Here we use a *-Do as I do-* paradigm to study the abilities of a killer
23 whale to imitate novel sounds uttered by conspecific (vocal imitative learning) and human models
24 (vocal mimicry). We found that the subject made recognizable copies of all familiar and novel
25 conspecific and human sounds tested and did so relatively quickly (most during the first 10 trials
26 and three in the first attempt). Our results lend support to the hypothesis that the vocal variants

27 observed in natural populations of this species can be socially learned by imitation. The capacity for
28 vocal imitation shown in this study may scaffold the natural vocal traditions of killer whales in the
29 wild.

30 Keywords: Vocal learning; imitation; mimicry; cetacean culture; do as I do; killer whale

31

32 **1. Introduction**

33 Learning a previously unknown behaviour by observation from another individual [1] enables the
34 non-genetic transfer of information between individuals and constitutes a potential driver for the
35 diffusion and consolidation of group-specific behavioural phenotypes (i.e., traditions and cultures)
36 [2,3]. Imitation of novel sounds, also referred to as vocal production learning [4] and defined as the
37 ability to learn to produce a novel sound just from hearing it, is a core property of human speech
38 which, along with other cognitive skills, has fuelled the evolution of another adaptation uniquely
39 evolved in our species, human culture [5]. Comparative evidence has revealed that although the
40 ability to copy sounds from conspecifics is widespread in birds, it is strikingly rare in mammals
41 [4,6], and among primates it is unique to humans [7,8, but see 9]. Cetaceans are one of the few
42 mammalian taxa shown to have evolved the ability for vocal production learning. Studies of several
43 cetacean species in the wild have revealed that they exhibit substantial behavioural diversity
44 between sympatric groups in terms of the acoustic features of their vocal repertoires (songs, calls)
45 [10]. Bottlenose dolphins (*Tursiops truncatus*) display individual recognition signature whistles,
46 humpback whales (*Megaptera novaengliae*) produce songs where some elements persist while
47 others evolve over generations, and sperm whales (*Physeter macrocephalus*) possess group-specific
48 coda repertoires [4,10,11]. It has been suggested that imitative learning can underpin these
49 behaviours with experimental evidence for the ability for sound imitation demonstrated mainly in
50 the bottlenose dolphin [11,12,13] and recently in the beluga (*Delphinapterus leucas*) [14,15].

51 Among cetaceans, the killer whale (*Orcinus orca*) stands out regarding the study of vocal

52 dialects in the wild [16]. Each family or matrilineal unit or pod within a population has been
53 documented to have a unique vocal dialect, including a combination of unique and shared call types
54 [17-19]. These dialects are believed to be transmitted via social learning [16-18], not only from
55 mother to offspring (vertical transmission), but also between matrilines (horizontal transmission)
56 [18-21]. Moreover, the similar acoustic features found between different populations in the same
57 area do not correlate with geographic distance [22]. Since many of these group-differentiated
58 signatures are not accounted for by ecological factors or genetic inheritance, the hypothesis that
59 they may have been acquired through social learning, particularly imitation, appears plausible [16-
60 24].

61 Elucidating the precise mechanism of social learning involved is difficult, however, particularly
62 for acoustic communication in wild populations. Although killer whales have been shown to be
63 capable of learning novel motor actions from conspecifics through imitation [25], the experimental
64 evidence for production imitation skills in the vocal domain is still scarce in this species. There are
65 reports on killer whales in the field and in captive settings indicating that they can copy novel calls
66 from conspecifics [26,27] and even from heterospecifics such as bottlenose dolphins [28] or sea
67 lions [24]. One Icelandic female was found to match novel calls from a Northern Resident female
68 with whom she had been housed together for several years [26]. Two juvenile killer whales,
69 separated from their natal pods, were observed to mimic the barks of sea lions in a field study [24].
70 Crance et al. [27] and Musser et al. [28] took advantage of two unplanned cross-socializing
71 experimental situations to show that two juvenile males learned novel calls from an unrelated but
72 socially close adult male, and three individuals learned novel whistles from a dolphin, respectively.

73 However, as suggestive as these reports of killer whales copying sounds from other individuals
74 are, the lack of experimental controls curtails the interpretation about the underlying acquisition
75 mechanisms. Experimental data are needed to ascertain whether vocal learning is a plausible
76 mechanism underlying the complexity of vocal traditions in killer whales in the wild. However, to

77 the best of our knowledge, not even anecdotal reports exist about killer whales spontaneously
78 mimicking human speech similar to those reported in some birds (e.g., parrots [29], mynahs [30])
79 and mammals (elephants [31] seals [32], belugas [14]).

80 In most mammals, sound production occurs in the vocal folds within the larynx (the sound
81 source) and the supralaryngeal vocal tract, consisting of pharyngeal, oral, and nasal cavities (the
82 filter) [33]. In humans, this apparatus increases in complexity due to the unusual neurological and
83 motor control that we can exert on these structures [33,34]. In contrast, toothed cetaceans (e.g.,
84 killer whales, belugas and dolphins) have evolved a pneumatic sound production in the nasal
85 complex passages (instead of the larynx) involving bilateral structures such as a pair of phonic lips,
86 that can operate as two independent sound sources and filters [35,36]. This difference in the sound
87 production system between toothed cetaceans and humans make the investigation of cetacean vocal
88 production particularly valuable for comparative analyses of flexible vocal production.

89 Here we report an experimental study of sound learning and mimicry abilities of a killer whale
90 listening to familiar or novel sounds uttered by a conspecific or a human model and requested to
91 reproduce them on command ('Do this!'). The *Do-as-I-do* paradigm [37] involves the copying of
92 another's untrained (familiar or novel) motor or vocal actions under a specific previously trained
93 signal in the absence of results-based cues. The Do-as-I-do training method has been successfully
94 used in studies of primates, birds, dogs, and two species of cetaceans [12, 25, 38]. In fact, this
95 method was previously used in a study of production imitation of novel motor actions in the group
96 of killer whales studied here [25]. Ultimately, we wanted to test the long-standing hypothesis that
97 the group-specific vocal patterns documented in wild populations of killer whales can be learned
98 socially and, more specifically, through production imitation learning.

99 **2. Methods**

100 **(a) Subjects**

101 We tested a 14 year-old female killer whale (*Orcinus orca*), named Wikie, housed at Marineland
102 Aquarium in Antibes, France. The conspecific model was her own 3 years old calf, named Moana,
103 born in Marineland. Wikie had been trained for a variety of examination and exercise behaviours
104 with standard operant conditioning procedures and fish/tactile positive reinforcement. Also, she had
105 participated in a previous experimental study of action imitation [25], so she was already trained
106 with the ‘copy’ command.

107 **(b) Procedure**

108 The study comprised three phases. *Phase 1* involved retraining and reinforcing the subject to
109 respond to the gesture-based command ‘copy’ (‘Do that!’) given by the trainer, that had been used 4
110 years earlier in the previous study of action imitation aforementioned [25]. *Phase 2* involved testing
111 the subject’s response to the trainer’s copy command when the model uttered familiar vocalizations
112 (n = 3 different sounds), that is, vocalizations that the subject had already performed herself, either
113 because she had been trained with them or because they were part of her natural repertoire (see
114 Table 1). Finally, *Phase 3* involved testing the subject with novel sounds (n = 11 different sounds),
115 that is, sounds that were unknown to the subject in terms of neither having heard them, nor having
116 been uttered by her previously. To ensure that the unfamiliar sounds (conspecific and humans) were
117 as different as possible from what they had produced before we compared them with 278 sound
118 samples extracted from ‘Hodgins’ sound recording baseline of the vocal repertoire in this same
119 group of killer whales [39], where she had identified up to eleven distinct discrete call types and we
120 found no matching with our sample of novel conspecific or human sounds. In addition, before
121 running the experiment we recorded 28 hours of in-air spontaneous sounds produced by the killer
122 whales during their free time to see if the subject (or any other killer whale in the group) uttered
123 sounds similar to the novel sounds in our sample. (Further details are given in the ESM.) *Phase 3*
124 comprised two testing conditions: a conspecific model (condition 1) and a human model (condition
125 2). In condition 1, the subject first listened to a conspecific model’s performance that included three

126 familiar sounds and five novel sounds (test trials), and then was signalled to copy them. The sounds
127 were presented in two formats: 1) performed by a killer whale model live and 2) played through a
128 speaker (e.g. conspecific sounds like airy atonal sounds as ‘Breathy’ and ‘Strong’ raspberries, or
129 tonal whiny sirens sounds like ‘Wolf’). In condition 2, the subject also listened to three familiar and
130 six other novel sounds (test trials), but now they were produced by a human model (e.g. human
131 sounds like a human laugh ‘Ah Ah’ or human words like ‘One Two’ (Table S1 gives the complete
132 description of each sound). In the two conditions, the sounds were presented with the constraint
133 that no more than three consecutive test trials of the novel sound could occur in a row. In each
134 session, a single novel sound was presented to the subject at a time. We also interspersed the three
135 familiar sounds that had been used in the previous phases and control trials consisting of ‘non-copy’
136 trials during which the subject’s trainer did not make the copy sign and asked for any other trained
137 action that the subject regularly was requested to perform during the aquarium shows. Therefore,
138 sessions consisted of several familiar sounds and control trials and from six to ten test trials of the
139 novel sound. The subject was positively reinforced with fish and/or tactile and voice reinforcement
140 signals whenever she yielded a correct response as judged in real time by two observers (Wikie’s
141 trainer and one experimenter), but only when she was asked to copy familiar sounds or perform
142 familiar actions (control trials). During the test trials (novel sounds from conspecific and human
143 models), the subject received no rewards irrespective of whether she responded correctly or not, so
144 that the experimenter did not provide any cues, thus making real time judgments unnecessary.
145 Altogether, phase 1 lasted one session, phase 2 lasted seven sessions and phase 3 fifty- two
146 sessions. All the sounds were asked and performed when the subject’s head was above the water
147 surface with her blowhole exposed.

148 Three different set-ups were used. (a) *Conspecific live condition*: The two trainers (T_M and T_S ;
149 M for model and S for subject) were positioned on different sides of a wooden panel 2m long x 1.90
150 cm high placed in a position in which S and M could see each other and their own trainer, but could

151 not see the other trainer's commands. T_M was positioned on the right side of the panel, and T_S was
152 on the left side; thus, the trainers were in a position from which they were not able to see each
153 other's signals either (see figure 1). (b) *Conspecific speaker condition*: two trainers were also
154 required, one trainer held the speaker and another (T_S) gave the copy command to the subject; and
155 (c) *Human live condition*; just one trainer was needed, as he both uttered the sound and gave the
156 'copy' signal (see figure 1). Table 1 gives the complete list of sounds by phase examined in this
157 study and Table S1 gives the description of sounds. Audio samples of each demonstrated sound and
158 of the subject's copy are available in the electronic supplementary material.

159 All sessions were videotaped and were recorded with Fostex Fr2 and Zoom H-4N digital
160 recorders and a Rode NTG-2 condenser shotgun microphone. To play the sounds in the speaker
161 condition a sound launcher app for iOS 'SoundPad Live' was developed. The sounds were played
162 through an Ipad to an Ik Multimedia 'I Loud' portable Bluetooth speaker.

163 **(c) Coding and data analysis**

164 The analysis comprised two steps. In the first step we used a traditional method of categorization
165 that consisted of using acoustic inputs and making a selection of the sounds that looked more
166 similar [23,26,39-41]. That is, one experimenter listened to each test trial, and scored whether the
167 subject's vocal response correctly matched the sound uttered by the model. Then, for reliability
168 analysis, six naïve judges, blind to the model's true sound were presented with pair of sounds
169 (model and candidate copies) and were asked to judge if the copy matched the model sample
170 (scoring Yes for correct matching or No for non-matching) across 6 samples (3 correct and 3
171 incorrect, the latter chosen randomly from the pool of sounds emitted by the subject) for each
172 demonstrated sounds.

173 Next, using a visual inspection of the wave form we analysed two time domain-related parameters,
174 namely, the number and duration of bursts, of a random sample of 5 copies of each novel
175 vocalization using Adobe Audition and then we calculated the intraclass correlation coefficient

176 (ICC) as a measure of concordance between model and copy sounds. The ICC for absolute
177 agreement was estimated using a two-way random effects model.

178 We also run an objective detailed analysis in which the demonstrated and imitated sounds
179 selected in the first step were subjected to an analysis of matching accuracy using algorithms
180 implemented in Matlab version 2014a, using the signal processing toolbox Version 6.21
181 (R2014a) and the additional code and scripts designed by Lersch 2011 [42] available at
182 <http://www.audiocontentanalysis.org/code/>. These analyses went through several steps.

183 First, we selected and extracted a subset of acoustic features (e.g. statistics, timbre or quality of
184 sound, intensity-related, tonal or temporal) of both model-copy time-variant sounds that allowed us
185 to compare sounds produced with the remarkably different acoustic modes of production
186 aforementioned. These features form a compact informative set with respect to the desired
187 properties of the original data [42]. All of these features were implemented using a 20 ms time
188 window, hamming windowing, with an overlap of 50 % (hop 10 ms).

189 The challenge was to select in an exploratory approach a subset of these features in time and
190 frequency domains that a priori seemed suitable for comparing sounds made by two species that use
191 totally different production mechanisms. The main features selected were as follows: 1) *Spectral*
192 *Pitch Contour ACF* (Autocorrelation Function of the Magnitude Spectrum), that shows the
193 evolution of the fundamental frequency over time; 2) *Time Energy Evolution*, that allows to
194 compare the evolution of the energy pattern over time between the model's and the subject's
195 acoustic signals (temporal regularity and rhythm); 3) *Pitch Class Profile*, a histogram-like 12-
196 dimensional vector (corresponding to the 12 notes of the diatonic musical scale) with each
197 dimension representing both the number of occurrences of the specific pitch class in a time frame
198 and its energy or velocity throughout the analysis block [42]. Figure 2 presents an example of a
199 *Wave form*, *Spectrogram* and *Pitch Class Profile* of the demonstrated and the copy of the human
200 (tonal) novel sound 'Hello', and of the conspecific (atonal) novel sound 'Breathy Raspberry'

201 acoustic analyses. (See figures S2-S4 in the electronic supplementary material for one example for
202 each spectral analysis for each of the main features selected and for a complete list of all features
203 selected.)

204 Second, once these features were selected all the characteristics of each frame were compacted
205 into a single vector. Finally, for the comparison it was necessary to then take into account that these
206 signals were of different duration. We utilized a *Dynamic Time Warping (DTW)* method to deal
207 with the alignment task, that is, with the operations of stretching and compressing audio parts
208 allowing similar shapes to match even if they are out of phase in the time domain. DTW represents
209 a family of algorithms developed for the automated recognition of human speech that allows for
210 limited compression and expansion of the time axis of a signal to maximize frequency overlap with
211 a reference signal [42]. DTW is a more robust distance measure for time series capable of
212 quantifying similarity (or dissimilarity) in an optimal way [42] as, typically, dissimilarity function is
213 a Euclidean distance measure that calculates and cumulates a cost according to a correspondence
214 function (where a zero cost indicates a perfect match). That is, the higher the matching cost, the
215 more dissimilar (less similar) the two sequences.

216 DTW has been widely documented and used in digital signal processing, artificial intelligence
217 tasks such as pattern recognition (e.g., sign and gestural language), music information retrieval and
218 signal processing, audio forensic or machine learning [42] and has recently proven to be an
219 excellent technique for assessing matching accuracy between sounds produced by marine mammals
220 and in particular for automatic classification of killer whale call types [43-,45]. In the present study,
221 DTW was used to measure dissimilarity of the aforementioned acoustic subset of features that were
222 previously selected between the audio signal of the demonstrated sound and that of the subject,
223 revealing the extent of alignment or synchronization between both signals.

224 Finally, in order to establish relative comparisons between any model-copy sound pair a
225 ‘dissimilarity index’ scale was constructed, which allowed us to calibrate the distance measures

226 obtained in the DTW analyses and thus establish how similar or dissimilar were the two sounds
227 (demonstrated sound and that of the subject) in all the subsets of features selected. Since the
228 dissimilarity index does not have a fixed upper limit, we rescaled the index into an interval from 0
229 to 1 to quantitatively assess the degree of dissimilarity. As in the non-rescaled version, 0 in this
230 scale represents a perfect copy (i.e., a sound compared with a copy of itself) and 1 represents
231 maximum dissimilarity. To establish this ceiling value (the top of the scale) we chose a main
232 benchmark value, technically referred to as ‘anchor’. Since the value depends on the particular
233 vocalizations analysed, indices of dissimilarity were calculated between four randomly chosen
234 demonstration sounds and copies uttered by the subject that corresponded to other different
235 demonstrated sound. The benchmark value chosen was the round score closest to the maximum
236 found (940378 score for ‘Amy’ paired with ‘One Two Three’), which accordingly in this case was
237 rounded to 1000000 (See ESM for a complete list of DTW dissimilarity index scores.) The rescaled
238 dissimilarity index represents the division of the accumulated distance in relation to the distance
239 value of the anchor of dissimilarity. Among these same four pairs of different sounds we also took
240 the lowest score (the more similar) as another benchmark for what could be considered bad and
241 good copies. Finally, another benchmark was included to serve as a reference point for what could
242 be considered a ‘high quality match’ (i.e. a human copying another human known word). For this
243 we calculated the dissimilarity index between the sound ‘Hello’ produced by the trainer and the
244 experimenter copy of the same sound (see figure 4).

245 **3. Results**

246 Inter-observer reliability of whether model and subject sounds matched was high (Fleiss’weighted
247 kappa: 0.8; $p < 0.001$; Observed agreement = 0.90).

248 (a) Familiar sounds

249 The subject correctly copied all of the trained sounds, either demonstrated by a conspecific or by a
250 human. In *Phase 1* the subject recalled the copy command given by the trainer 4 years before as

251 indicated by her response in the first trial. *Phase 2* involved testing the subject's response to the
252 trainer's copy command when the model uttered familiar sounds. With the copy signal alone the
253 sound 'Song' was copied in the 1st trial, 'Blow' was copied in the 2nd trial (first session) and
254 'Birdy' was accurately matched in the 34th trial (sixth session). The criterion required for moving to
255 the final experimental phase, i.e., 90 % of correct trials, on these three intermixed familiar sounds
256 was achieved by Wikie in the seventh session. In *Phase 3* the subject also copied correctly all of the
257 trained conspecific sounds performed by a human model in the transfer sessions (n = 2) and in the
258 first trial. In sum, the subject made recognizable copies of the demonstrated sound judged in real
259 time by two observers, Wikie's trainer and one experimenter, and then confirmed by both of them
260 listening to the recordings.

261 (b) Novel sounds

262 The subject produced recognizable copies of all of the untrained sounds, either demonstrated by a
263 conspecific or by a human (as judged by two experimenters that listened to the sound recordings
264 after the test and then confirmed by 6 independent observers). In the *live conspecific condition* the
265 novel sounds (n = 3) were copied before the 10th trial ('Strong Raspberry'), with one sound copied
266 in the 2nd trial ('Creaking Door'), and the other in the 3rd trial ('Breathing Raspberry'). In the
267 *conspecific through speaker condition*, the novel sounds (n = 2) were copied before the 17th trial
268 ('Wolf'), with the other sound copied in the 6th trial ('Elephant'). In the *conspecific through human*
269 *model condition* the novel sound tested (n = 1) was copied in the first trial ('Strong Raspberry').
270 Finally, in the *human sound condition* the novel sounds (n = 6), although they weren't perfect
271 copies, Wikie produced recognizable copies of the human model sounds before the 17th trial ('Ah
272 Ah'), with two sounds copied in the first trial ('Hello ' and 'One, Two, Three').

273 Visual examination of spectral patterns revealed a good matching of the demonstrated sound
274 and the subject's copy in several of the acoustic features analysed. For all sound parameters tested,
275 no differences were observed between the model's sound and the subject's match in the *total*

276 *number of bursts* (Cohen's kappa = 1, $p < .0005$). When tested with novel conspecific sounds, a
277 high concordance was found between *burst duration* of the model's sound and the subject's copy
278 (ICC: 0.79; $p < 0.001$, N=31 bursts). When tested with human sounds, a very high concordance
279 between *burst duration* of model's sound and subject's copy was found (ICC: 0.89; $p < 0.001$,
280 N=65 bursts) showing better performance compared to killer whale sounds.

281 In the automated quantitative analysis, the DTW showed an optimal overlap represented by a
282 diagonal line alignment between both sounds (demonstrated and copy) in all the examples for each
283 sound judged by the experimenters as correct imitations in phase 1. This diagonal line alignment of
284 the 'shortest line' between both signals indicated similarity in all features selected [42]. Figure 3
285 presents an example of a DTW analysis in the matching of the subject's and the human model's for
286 the sound 'Hello' (tonal); the conspecific's novel sound 'Breathy Raspberry' (atonal) and the
287 familiar sounds 'Birdy' (tonal) and 'Blow' (atonal). (See figure S1 in the electronic supplementary
288 material for one DTW example of all the others novel sounds tested). Although the fundamental
289 frequency of copies made by human and killer whale models was remarkably dissimilar, the outline
290 F0 contours turned out to be very similar. Figure 4 shows a representation of a DTW distance
291 dissimilarity index between the demonstrated sound and the best match (the lowest DTW value)
292 among the random sample of 5 copies of each vocalization type of the subject for each and every
293 sound tested plus four 'incorrect' reference control points (corresponding to randomly chosen
294 demonstrated sounds paired with copies that corresponded to other different subject's sound and
295 another 'high quality copy' reference control point (human copying another human known word),
296 (see ESM for a complete list of DTW dissimilarity index scores). Overall, expected matches (when
297 demonstration and copy were of the same sound type) did match, while expected non-matches
298 (when demonstration and copy were of different sound types) did not. Specifically, we found that
299 copies of *familiar* conspecific sounds fell below a dissimilarity index threshold (horizontal red
300 dotted line below the lowest incorrect random pair copy) that divided our results in good or bad
301 copies and most of them were close to the 'high quality match' score (human imitating human

302 anchor), with one score being below this value ('Blow'). Copies of *novel* conspecific sounds were
303 located very close to this 'high quality match' score and *novel* speech sounds demonstrated by
304 humans were distributed across the whole range of good copies with one even below this 'high
305 quality match' benchmark. If we take as a criterion of matching accuracy the values obtained with
306 familiar sounds from conspecifics, we observe that except for the sound 'Blow', which is the
307 simplest untrained sound consisting only of a single burst of atonal voiceless breath (see electronic
308 supplementary material second example on Sound File N°1), the copies of *novel* conspecific sounds
309 and three of *novel* speech sounds ('Amy', 'Hello' and 'Ah Ah') were even more closely matched
310 than were tonal *familiar* conspecific sounds.

311 Finally, analysing the features selected for the DTW analysis separately, the spectrogram
312 analysis revealed that the subject produced harmonics when exposed to tonal sounds, but not when
313 exposed to atonal or noisy sounds (see figure 2 and electronic supplementary material figures S2-
314 S4). This pattern held even for the human tonal sounds.

315 **4. Discussion**

316 Although the subject did not make perfect copies of all novel conspecific and human sounds,
317 nonetheless, they were recognizable copies as assessed by both external independent blind
318 observers and the acoustic analysis. There was great variability in the number of good copies
319 produced after a sound was copied for the first time (Table 1). Possible factors that could explain
320 this variability are the difficulty in producing novel sounds and some uncontrolled factors such as
321 variation on motivational levels and social dynamics across sessions. Additionally, our non-
322 differential reinforcement regime (good copies of novel sounds were not reinforced to avoid
323 shaping) may have also contributed to this variability. Consequently, it is conceivable that our data
324 represent a conservative estimate of the killer whale's capacity for vocal imitation.

325 According to the DTW dissimilarity scale (figure 4), all the copies of novel conspecific
326 utterances fell below the dissimilarity index threshold for good and bad copies (pairs of different

327 demonstrated and copied sounds randomly chosen) and most of them were close or even fell below
328 the ‘high quality match’ score, as represented by the human-copying-human anchor. Similarly,
329 although three of the copies of human sounds were only close to the dissimilarity index threshold
330 for good and bad copies (incorrect randomly paired copies), the other three fell close to the ‘high
331 quality match’ score (human imitating human anchor); that is, they were very accurate copies, with
332 one falling even below this benchmark. This level of accuracy is particularly remarkable given that
333 the subject possessed a very different sound production system compared to humans. Some
334 parameters such as the fundamental frequency were sometimes drastically different between the
335 human model and the killer whale copies, but the outline F0 contours were nonetheless quite similar
336 (figure 4).

337 Overall, the DTW analyses revealed that the accuracy of copies was much higher when these
338 were of the same sound than when they involved a different sound, which strongly suggests that the
339 copies were specific to the demonstrated sound. We believe that the subject’s responses represent a
340 case of *vocal imitation* rather than response facilitation, as the latter form of social learning does not
341 apply to individuals reproducing a model’s novel sound [46]. Moreover, the subject’s perfect
342 performance in the control ‘non-copy’ trials in which she was requested to perform a trained action
343 or sound different from that of the model, ruled out automatic response facilitation (i.e., copying the
344 model’s sound spontaneously) [46] because she only copied what she was requested to do so.

345 DTW analyses also revealed that the subject’s copies of *novel* conspecific and human sounds
346 were in most cases even more accurate than were the copies of *familiar* sounds. Thus, in three of
347 the novel speech sounds (‘Hello’, ‘Amy’ and ‘Ah Ah’), the accuracy of the copies was even greater
348 than the matching accuracy of some of the familiar sounds uttered by the conspecific model.
349 Moreover, four copies of novel sounds were found to be high quality matches, as they were close to
350 the benchmark score of a human copy of the human sound, and one was even a better match (see
351 ‘Breathy Raspberry’ in figure 4). A greater copying accuracy for novel compared to familiar sounds

352 might suggest that the cognitive mechanisms responsible for producing familiar and novel sounds
353 do not fully overlap. It is possible that the matching of familiar sounds relies more heavily on
354 response facilitation than imitation where the subject's copy is mainly shaped by the *general*
355 characteristics of the stored representation than by the sound's *specific* individual components. In
356 contrast, learning to match a novel action or sound might require the subject to carefully process the
357 individual components of the auditory experience, which might generate a better match. The
358 subject's matching accuracy is all the more remarkable as she was able to accomplish it (a) in the
359 absence of extensive trial-and-error across all the experimental conditions, (b) in response to sounds
360 presented in-air and not in-water (the species' usual medium for acoustic communication), and (c)
361 in the case of her matching of speech sounds, through the use of a sound production system that
362 greatly differs from that of the model's [35, 36]. Note that the subject readily matched the harmonic
363 quality of human tonal sounds (see figure 2 and electronic supplementary material figures S2-S4).
364 The anatomical structures involved in sound production of cetaceans differ from those used by
365 terrestrial mammals and birds in that cetaceans are adapted to an aquatic lifestyle where the sound
366 producing organs compress while diving because of water pressure related changes [35]. This has
367 been hypothesized to have favoured the development of vocal learning in marine mammals as they
368 need to have a substantial voluntary control over sound production in order to successfully meet the
369 demands of reliably generating the same sounds at different depths [47].

370 Our experimental findings lend support to the hypothesis that the group-differentiated acoustic
371 dialects that have been documented in many field studies of killer whales [16-23] and other
372 cetaceans [10] can be acquired and maintained through social learning and, more specifically,
373 through imitation. These results add to the growing database of socially learned sounds reported in
374 previous non-experimental and experimental studies of killer whales and other cetaceans (dolphins
375 [11-13]; belugas [14,15]). As a mammalian order, cetaceans stand out for their complex sociality,
376 elevated encephalization, and advanced cognitive skills [48]. Compared to the fission-fusion
377 societies of bottlenose dolphins, however, the social systems of killer whales are reported to be

378 more strongly structured and closed [10,16]. Thus, the well-developed propensity of killer whales to
379 copy what others are doing, that is, to translate visual or auditory input into motor responses that
380 conform to the group's norm would be consistent with the body of observations on group-specific
381 acoustic dialects, synchronized behaviour, and sophisticated cooperative strategies documented in
382 this species [10].

383 The results reported here show that killer whales have evolved the ability to control sound
384 production and qualify as open-ended vocal learners. It can be argued that since our experimental
385 design included in-air (rather than in-water) sounds, the positive results obtained cannot directly
386 reflect the killer whales' capacity for learning to copy underwater sounds in their natural
387 environment. However, our main objective was to test whether the killer whales were capable of
388 learning novel sounds through imitative learning, regardless of the type of sound (in-air vs. in-
389 water) and the model (conspecifics vs. heterospecifics). The atypical nature of the sounds that we
390 used represents a strength rather than a weakness in relation to our main question because it
391 demonstrates flexibility not just on *what* is copied but on *how* is copied. With regard to what is
392 copied, our data demonstrate that killer whales can copy sounds outside their usual repertoire –
393 which is an important piece of information if one wants to know not only know what a species does,
394 but also what it can do, under a variable set of circumstances. With regard to the issue of how it is
395 copied, our data might indicate that the sensory-perceptual and cognitive skills recruited in
396 imitating in-air sounds are ancestral traits, dating back to the terrestrial ancestors of cetaceans.
397 Moreover, given the highly derived state of the sound producing apparatus uniquely evolved by
398 cetaceans, the imitative capacities found in this study also underscore the fine-tuned ability of this
399 species to flexibly produce accurate matches of heterospecific in-air sounds.

400 Future experimental studies of imitation of in-water sounds demonstrated by conspecifics are
401 needed to firmly establish the role of social learning in the killer whale's vocal dialects documented
402 in the wild. Another challenge for future research is to ascertain whether the neural and cognitive

403 scaffolding for vocal learning in cetaceans and humans (and other taxa) are homologous or
404 analogous, and whether they are adaptations or have been co-opted for new fitness-enhancing
405 functions in the unique suite of environmental challenges they encounter in the seascape they
406 inhabit [6,10,11,47,48]. Finally, we extended DTW analysis used in previous studies [39,44,45] by
407 incorporating several additional features of killer whales' demonstrated and imitated sounds into the
408 algorithm. However, these results must be taken with caution because the choice of features was
409 exploratory. Further studies are thus needed to standardize the assessment of the matching accuracy
410 of different sound features as well as the validation of the dissimilarity index. Although we see
411 great potential in this analytical approach for comparative studies of vocal learning, its applicability
412 may vary depending on the study's objectives, the sounds investigated, and the species' vocal
413 production system.

506 <https://figshare.com/s/2991d28752ca0690e843>. This includes methods details, raw data, figures S1-S5, and 12 audio files examples
507 (ESM Audio File S1: 3 conspecific familiar sounds; ESM Audio File S2.1-S2.5: 5 conspecific novel sounds; ESM Audio File S3.1 –
508 S3.6: 6 human novel sounds).

510 **Ethics.** The Ethics and Animal Welfare Committee (CEBA-MEDUC) of the School of Medicine, Pontifical Catholic University of
511 Chile, have approved this research. This research adhered to the legal requirements of the country (France) in which the work was
512 carried out and Marineland institutional guidelines.

513 **Data accessibility.** The datasets supporting this article have been uploaded as part of the supplementary material and at
514 <https://figshare.com/s/2991d28752ca0690e843>.

515 **Author Contributions** J. Z.A. conceived the study. J.Z.A., M.V.H.LL and J.C. designed the experiment, which was conducted by
516 J.Z.A. and M.V.H.LL. M.V.H.LL designed and carried out the data analyses and interpretation. J.Z.A. and L.G. performed the sound
517 analyses and interpretation. J.Z.A. and M.V.H.LL drafted the paper. J.Z.A. and F.C. co-wrote the paper. J.C. and F.A. helped to write
518 and provided critical revisions and some of the ideas in the paper. J.Z.A., F.C., F.A. and J.C. provided financial support. All authors
519 have read and approved the final manuscript.

520 **Acknowledgements** Special thanks go to Andrea Hodgins for sharing her data and making her thesis available to us and
521 to Manuel Castellote for his advice on sound analyses. We are grateful to the directors of Parques Reunidos and the Marineland
522 Aquarium of Antibes, Jesús Fernández and Jon Kershaw for allowing us to conduct this research. Furthermore, we appreciate the
523 work of head coaches Lindsay Rubinacam and Duncan Versteegh, and all orca trainers team for their help and support. Special
524 thanks go to Amy Walton for her dedication and training of the killer whale model Moana. Finally we want to thank Francisco
525 Serradilla from Universidad Politécnica de Madrid for developing the sound launcher app for iOS.

526 **Funding** This project was conducted at the Marineland Aquarium Antibes, France and supported by a Postdoctoral Scholarship
527 FONDECYT N° 3140580 to J.Z. Abramson. This study was partly funded by project grants PSI2011-29016-C02-01, PSI2014-
528 51890-C2-1-P (MINECO, Spain) and UCM-BSCH GR3/14-940813 (Universidad Complutense de Madrid y Banco Santander
529 Central Hispano) to F. Colmenares.

530 **Competing interests:** The authors declare that they have no competing interests.

535 **Figure 1. Experimental set up.** (a) Conspecific live condition: The two trainers (T_M and T_S ; M for model and S for
536 subject) were positioned on different sides of a wooden panel 2m long x 1.90cm high placed in a position in which S
537 and M could see each other and their own trainer, but could not see the other trainer's commands; (b) conspecific
538 speaker condition: One trainer holds the speaker and another (T_S) gave the copy command to the subject; and (c) human
539 live condition; Just one trainer was needed, as he both uttered the sound and gave the 'copy' signal.

540 **Figure 2.** *Wave form and spectrogram* of the model (a1) and the copy (a2) of the human (tonal) novel sound 'HE'. Note
541 the harmonic pattern in both signals. 'HE' *Pitch Class profile* of the model (b1) and the copy (b2) *Wave form and*
542 *spectrogram* of the model (c1) and the copy (c2) of the conspecific (atonal) novel sound 'BR'. Note the in harmonic
543 pattern in both signals. 'BR' *Pitch Class profile* of the model (d1) and the copy (d2)

544 **Figure 3. Dynamic Time Warping Familiar and Novel Conspecific and Human Sounds (Tonal and Atonal).** In
545 both axes all the characteristic features of the signals are aligned and the black line shows the. shortest path (minimum
546 distance) between the model and the observer sounds streams.. (a); DTW familiar sound 'BL' (atonal) of the model and
547 the copy (b); DTW familiar sound 'BI' (tonal) of the model and the copy (c); DTW novel sound 'HE' (tonal) of the
548 model and the copy (d); DTW novel sound 'BR' (atonal) of the model and the copy.

549 **Figure 4 Dynamic Time Warping dissimilarity index distribution.** Distribution of the DTW dissimilarity index
550 between the model and the copy for each vocalization; familiar (blue dots), killer whale novel (green dots) and human
551 novel (turquoise dots). Five control benchmarks (red dots) separated by a red vertical dotted line are also
552 represented, where the first one correspond to the 'high quality match' score (human imitating human benchmark) and
553 the others correspond to the four randomly chosen incorrect copies (model sounds paired with copies that corresponded
554 to other different models). The horizontal red dotted line below the lowest incorrect random pair copy serves as a
555 benchmark for dividing the results between good and bad copies.

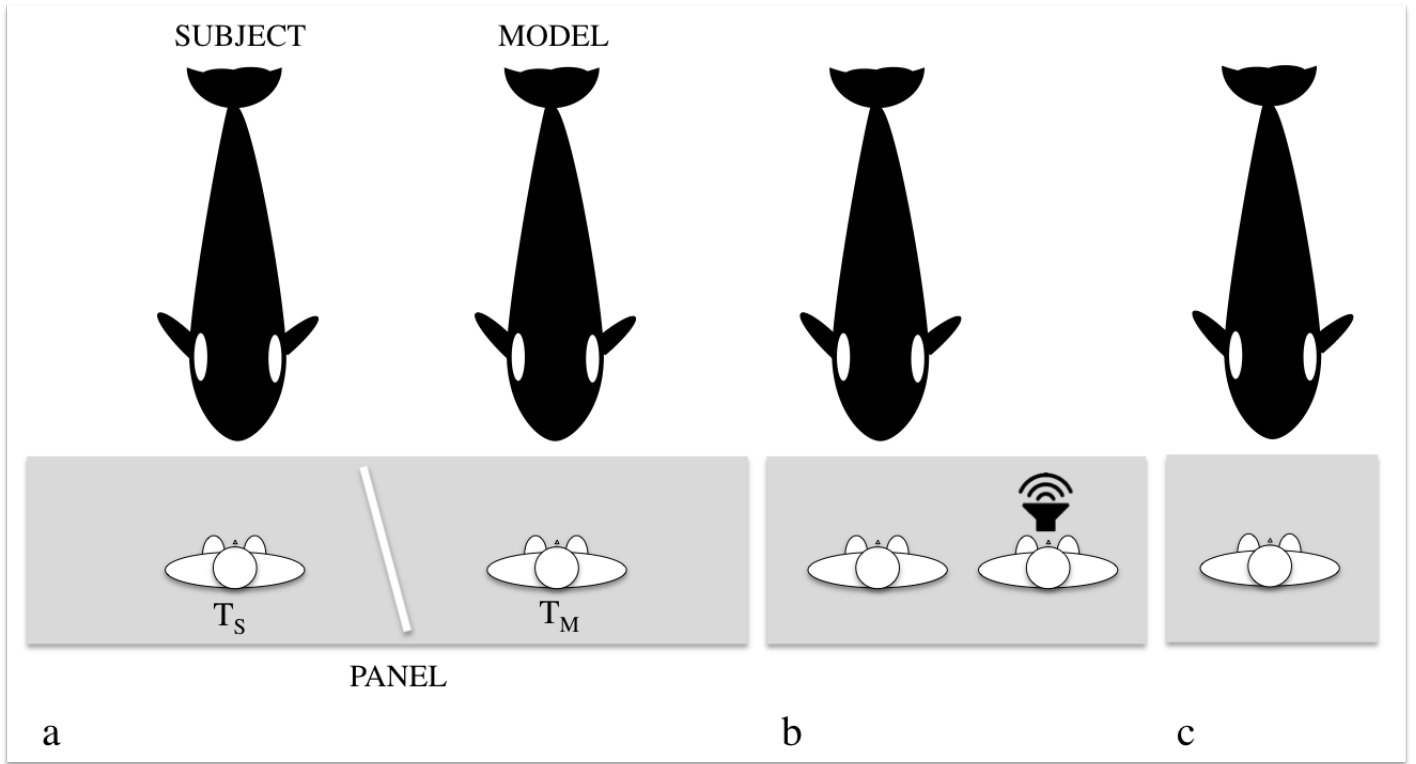

556

557 **Table 1.** Total number of trials for each sound tested, number of trials until the model's sound was judged to be copied
 558 by the subject (according to two experimenters that listened to the sound recordings after the test and then confirmed by
 559 6 independent observers), and percentage of correct trials since the first full copy

	No. of trials	First trial copied	% correct since the 1st copy
