# Compact Differences of Composition Operators on Bloch and Lipschitz Spaces 

Pekka J. Nieminen

(Communicated by Peter Duren)

#### Abstract

We consider the difference $T=C_{\varphi}-C_{\psi}$ of two analytic composition operators in the unit disc. We characterize the compactness and weak compactness of $T$ on the standard Bloch space, improving an earlier result by Hosokawa and Ohno. We also characterize the compactness and weak compactness of $T$ on analytic Lipschitz spaces. These characterizations are derived from a general result dealing with differences of weighted composition operators on weighted Banach spaces of analytic functions. We also make complementary remarks on the compactness properties of a single composition operator on the Lipschitz spaces and answer a question of Cowen and MacCluer on the boundedness of such an operator.

Keywords. composition operator, compactness, difference, Bloch space, Lipschitz space.

## 1. Introduction

Let $\mathbb{D}$ be the unit disc of the complex plane and assume that $\varphi: \mathbb{D} \rightarrow \mathbb{D}$ is an analytic map. Then the composition operator $C_{\varphi}$ taking $f$ to $f \circ \varphi$ is a linear operator on $H(\mathbb{D})$, the space of all analytic functions on $\mathbb{D}$. During the past few decades much effort has been devoted to the research of such operators on a variety of Banach spaces of analytic functions. The general idea has been to explain the operator-theoretic behaviour of $C_{\varphi}$, such as compactness and spectra, in terms of the function-theoretic properties of the symbol $\varphi$. We refer to the book by Cowen and MacCluer [4] for an overview of the field as of the mid-1990s.
A topic of considerable interest has been the inquiry into the topological structure of the set of composition operators acting on a given function space. In this

connection it also becomes relevant to analyse the mapping properties of composition operator differences. This line of research was initiated in the setting of the Hardy space $H^{2}$ by Berkson [1] and Shapiro and Sundberg [29], and in the setting of (weighted) Bergman spaces by MacCluer [17]. More recent works in this context are [27, 24, 23, 16]. Lately several authors have studied the same questions on spaces like $H^{\infty}$ and the Bloch space. In [18] MacCluer, Ohno and Zhao considered the set of composition operators acting on $H^{\infty}$ and provided function-theoretic characterizations for the cases when two composition operators lie in the same connected component or have a compact difference. Their results have been complemented and extended in [13, 11, 12, 30, 31, 9, 2]. For the case of composition operators on the Bloch space, Hosokawa and Ohno [14, 15] have described connected components and compact differences.
The present paper continues this line of research. We will study the compactness and weak compactness of a composition difference $C_{\varphi}-C_{\psi}$ on the Bloch-type spaces $\mathcal{B}^{\alpha}$ consisting of all analytic functions $f$ on $\mathbb{D}$ which satisfy the condition

$$
\sup _{z \in \mathbb{D}}\left(1-|z|^{2}\right)^{\alpha}\left|f^{\prime}(z)\right|<\infty
$$

It is well known that $\mathcal{B}^{\alpha}$ is a Banach space under the norm

$$
\|f\|_{\alpha}=|f(0)|+\sup _{z \in \mathbb{D}}\left(1-|z|^{2}\right)^{\alpha}\left|f^{\prime}(z)\right|
$$

(See the expository article [33] by Zhu for more information on these spaces.) Here $\alpha$ could be any positive number, but we will be mainly interested in the range $0<\alpha \leq 1$. Note that $\mathcal{B}=\mathcal{B}^{1}$ is just the standard Bloch space. For $0<\alpha<1$ it was proved by Hardy and Littlewood that a function $f$ belongs to $\mathcal{B}^{\alpha}$ if and only if it is analytic in $\mathbb{D}$ and satisfies a Lipschitz condition of order $1-\alpha$, that is,

$$
\sup _{z, w \in \mathbb{D}} \frac{|f(z)-f(w)|}{|z-w|^{1-\alpha}}<\infty
$$

(see [6, Thm. 5.1]). In fact, the two suprema above are comparable to each other. Moreover, one should note that every Lipschitz function in $\mathbb{D}$ is boundary-regular in the sense that it extends continuously to the closed unit disc.
Our results will involve the hyperbolic metric and related notions. For $z, w \in \mathbb{D}$, the pseudo-hyperbolic distance is defined by $\rho(z, w)=|z-w| /|1-\bar{w} z|$. The hyperbolic distance between $z$ and $w$ is then

$$
\inf _{\gamma} \int_{\gamma} \frac{|d \zeta|}{1-|\zeta|^{2}}=\frac{1}{2} \log \frac{1+\rho(z, w)}{1-\rho(z, w)}
$$

where the infimum is taken over all rectifiable arcs joining $z$ and $w$ in $\mathbb{D}$ (see [7, Sec. I.1]). When $\varphi$ is an analytic self-map of $\mathbb{D}$, we will use the short-hand notation

$$
\mathcal{D}^{\alpha} \varphi(z)=\left(\frac{1-|z|^{2}}{1-|\varphi(z)|^{2}}\right)^{\alpha} \varphi^{\prime}(z)
$$

and in the Bloch case $\alpha=1$ we just write $\mathcal{D} \varphi$ for $\mathcal{D}^{1} \varphi$. It should be noted that $\mathcal{D} \varphi$ is the hyperbolic derivative of $\varphi$ in the sense that

$$
|\mathcal{D} \varphi(z)|=\lim _{w \rightarrow z} \frac{\rho(\varphi(z), \varphi(w))}{\rho(z, w)}
$$

For a general $\alpha$ one can regard $\mathcal{D}^{\alpha} \varphi$ as a derivative relative to a metric induced by the arc length element $\left(1-|\zeta|^{2}\right)^{-\alpha}|d \zeta|$ (see [33, Sec. 4]).
The importance of $\mathcal{D}^{\alpha}$-derivatives to the study of composition operators on $\mathcal{B}^{\alpha}$ stems from the identity

$$
\begin{equation*}
\left(1-|z|^{2}\right)^{\alpha}\left|\left(C_{\varphi} f\right)^{\prime}(z)\right|=\left|\mathcal{D}^{\alpha} \varphi(z)\right| \cdot\left(1-|\varphi(z)|^{2}\right)^{\alpha}\left|f^{\prime}(\varphi(z))\right| \tag{1.1}
\end{equation*}
$$

which basically shows that the condition $\left\|\mathcal{D}^{\alpha} \varphi\right\|_{\infty}<\infty$ is sufficient for $C_{\varphi}$ to be bounded on $\mathcal{B}^{\alpha}$. For $\alpha=1$ this condition is always true: the classical SchwarzPick inequality actually says that $\|\mathcal{D} \varphi\|_{\infty} \leq 1$. For $0<\alpha<1$ this is not the case, and Madigan [20] observed that the condition is also necessary for the boundedness of $C_{\varphi}$ on $\mathcal{B}^{\alpha}$ (see also [4, Thm. 4.9]).
We are now ready to state our main results. Here we consider two analytic maps $\varphi, \psi: \mathbb{D} \rightarrow \mathbb{D}$ and we let $T=C_{\varphi}-C_{\psi}$. We also agree to write $\rho(z)=\rho(\varphi(z), \psi(z))$ for the pseudo-hyperbolic distance between $\varphi(z)$ and $\psi(z)$. Our first theorem deals with the standard Bloch case, characterizing the compactness and weak compactness of $T$.

Theorem 1.1. $T$ is (weakly) compact on $\mathcal{B}$ if and only if

$$
\begin{array}{ll}
\mathcal{D} \varphi(z) \rho(z) \rightarrow 0 & \text { as }|\varphi(z)| \rightarrow 1 \\
\mathcal{D} \psi(z) \rho(z) \rightarrow 0 & \text { as }|\psi(z)| \rightarrow 1 \tag{B2}
\end{array}
$$

Recently Hosokawa and Ohno [14, 15] characterized the compactness of $T$ on $\mathcal{B}$ by requiring (B1) and (B2) plus an additional condition which essentially says that

$$
\mathcal{D} \varphi(z)-\mathcal{D} \psi(z) \rightarrow 0 \quad \text { as }|\varphi(z)| \wedge|\psi(z)| \rightarrow 1
$$

(We use $\wedge$ to refer to the minimum of two real numbers, and $\vee$ to the maximum.) Our contribution is to show that this third condition is actually implied by (B1) and (B2), so it can be dispensed with.
To understand the conditions of Theorem 1.1, one should recall that Madigan and Matheson [21] showed that a single composition operator $C_{\varphi}$ is (weakly) compact on $\mathcal{B}$ if and only if $\mathcal{D} \varphi(z) \rightarrow 0$ as $|\varphi(z)| \rightarrow 1$. This is just a natural "little-oh" variant of the Schwarz-Pick inequality. On the other hand, the condition that

$$
\begin{equation*}
\rho(z) \rightarrow 0 \quad \text { as }|\varphi(z)| \vee|\psi(z)| \rightarrow 1 \tag{1.2}
\end{equation*}
$$

is known to guarantee the compactness of $T$ on various spaces, such as (weighted) Bergman and Dirichlet spaces and Hardy spaces (see [23, 16]). In fact, it was shown by MacCluer, Ohno and Zhao [18] that (1.2) characterizes when $T$ is compact on $H^{\infty}$ and also from $\mathcal{B}$ to $H^{\infty}$.

Our second theorem is concerned with the Lipschitz case $0<\alpha<1$. As mentioned above, we have to assume that the $\mathcal{D}^{\alpha}$-derivatives of the symbols are bounded so as to ensure the boundedness of the induced operators.

Theorem 1.2. Let $0<\alpha<1$ and assume that $\left\|\mathcal{D}^{\alpha} \varphi\right\|_{\infty}<\infty$ and $\left\|\mathcal{D}^{\alpha} \psi\right\|_{\infty}<\infty$. Then $T$ is (weakly) compact on $\mathcal{B}^{\alpha}$ if and only if

$$
\begin{align*}
\mathcal{D}^{\alpha} \varphi(z) \rho(z) & \rightarrow 0 & \text { as }|\varphi(z)| & \rightarrow 1,  \tag{L1}\\
\mathcal{D}^{\alpha} \psi(z) \rho(z) & \rightarrow 0 & \text { as }|\psi(z)| & \rightarrow 1,  \tag{L2}\\
\mathcal{D}^{\alpha} \varphi(z)-\mathcal{D}^{\alpha} \psi(z) & \rightarrow 0 & & \text { as }|\varphi(z)| \wedge|\psi(z)| \rightarrow 1 . \tag{L3}
\end{align*}
$$

Conditions (L1) and (L2) are obvious analogues of those in Theorem 1.1. In the present case, however, one has to impose the additional condition (L3) to guarantee the (weak) compactness of $T$. In fact, we will be able to construct symbols $\varphi$ and $\psi$, both satisfying Madigan's boundedness condition, such that (1.2) is satisfied but (L3) fails and consequently $T$ is non-compact on $\mathcal{B}^{\alpha}$.
We will approach Theorems 1.1 and 1.2 in a unified way. In fact, in Section 2 we will consider a very general setup where we have the difference of two weighted composition operators acting between two weighted $H^{\infty}$-type spaces. The proof of Theorem 1.1 occupies Section 3. In Section 4 we will deal with Theorem 1.2, especially addressing the necessity of condition (L3).
In Section 5, which is largely independent of the previous sections, we briefly revisit the theory of a single composition operator on the Lipschitz spaces. In particular, we will answer a question of Cowen and MacCluer on the boundedness of such an operator, which arises from an earlier work by Roan [25]. In addition, we will explore the function-theoretic relationship between various compactness criteria given in the literature.

## 2. Differences of weighted composition operators on weighted spaces

In this section we will consider the following general setup. Given analytic functions $\varphi: \mathbb{D} \rightarrow \mathbb{D}$ and $u: \mathbb{D} \rightarrow \mathbb{C}$ we define the weighted composition operator

$$
W_{\varphi, u}: H(\mathbb{D}) \rightarrow H(\mathbb{D}), \quad f \mapsto u(f \circ \varphi) .
$$

We also define the weighted function spaces

$$
H_{\alpha}^{\infty}=\left\{f \in H(\mathbb{D}): \sup _{z \in \mathbb{D}}\left(1-|z|^{2}\right)^{\alpha}|f(z)|<\infty\right\}
$$

for $0<\alpha<\infty$. These are Banach spaces under the norm determined by the above supremum, which we will denote by $\|f\|_{H_{\infty}}$. Montes-Rodríguez [22] and Contreras and Hernández-Díaz [3] have studied $W_{\varphi, u}$ as an operator acting
between this type of weighted spaces (with even more general weights). In particular, they have shown that $W_{\varphi, u}$ is a bounded operator from $H_{\alpha}^{\infty}$ to $H_{\beta}^{\infty}$ if and only if the pair $(\varphi, u)$ satisfies

$$
\begin{equation*}
\sup _{z \in \mathbb{D}} \frac{\left(1-|z|^{2}\right)^{\beta}|u(z)|}{\left(1-|\varphi(z)|^{2}\right)^{\alpha}}<\infty . \tag{2.1}
\end{equation*}
$$

They also characterized the (weak) compactness of $W_{\varphi, u}$ by the corresponding "little-oh" condition as $|\varphi(z)| \rightarrow 1$.
One should note that the differentiation map $f \mapsto f^{\prime}$ is a linear isometry from $\mathcal{B}^{\alpha}$ onto $H_{\alpha}^{\infty}$, provided that in $\mathcal{B}^{\alpha}$ we identify functions differing by a constant. Hence the unweighted composition operator $C_{\varphi}$ acting between Bloch-type spaces modulo constants is similar to the weighted composition operator $W_{\varphi, \varphi^{\prime}}$ acting between the corresponding weighted $H^{\infty}$-spaces. Since the identification of functions differing by a constant does not affect the boundedness or compactness properties of the operator (see e.g. [3, Sec. 6]), the above-mentioned general results yield conditions for the boundedness and (weak) compactness of $C_{\varphi}$ as an operator from $\mathcal{B}^{\alpha}$ to $\mathcal{B}^{\beta}$. These conditions have also been derived in [32]. In particular, if $0<\alpha=\beta<1$, then (2.1) yields Madigan's boundedness condition $\left\|\mathcal{D}^{\alpha} \varphi\right\|_{\infty}<\infty$.
Our goal here is to investigate the compactness of the difference of two weighted composition operators on weighted spaces of the above type. To this end we introduce analytic maps $\varphi, \psi: \mathbb{D} \rightarrow \mathbb{D}$ and $u, v: \mathbb{D} \rightarrow \mathbb{C}$ and look at the operator

$$
T=W_{\varphi, u}-W_{\psi, v}
$$

Our general theorem is the following. A related result for differences of composition operators has recently been obtained by Bonet, Lindström and Wolf [2]. Recall that we use $\rho(z)$ to denote the pseudo-hyperbolic distance between $\varphi(z)$ and $\psi(z)$.

Theorem 2.1. Let $\alpha$ and $\beta$ be positive real numbers, and assume that the pairs $(\varphi, u)$ and $(\psi, v)$ both satisfy (2.1). Then the above operator $T$ is (weakly) compact from $H_{\alpha}^{\infty}$ to $H_{\beta}^{\infty}$ if and only if

$$
\begin{array}{rlrl}
\frac{\left(1-|z|^{2}\right)^{\beta} u(z)}{\left(1-|\varphi(z)|^{2}\right)^{\alpha}} \rho(z) & \rightarrow 0 & \text { as }|\varphi(z)| \rightarrow 1, \\
\frac{\left(1-|z|^{2}\right)^{\beta} v(z)}{\left(1-|\psi(z)|^{2}\right)^{\alpha}} \rho(z) & \rightarrow 0 & \text { as }|\psi(z)| \rightarrow 1, \\
\frac{\left(1-|z|^{2}\right)^{\beta} u(z)}{\left(1-|\varphi(z)|^{2}\right)^{\alpha}}-\frac{\left(1-|z|^{2}\right)^{\beta} v(z)}{\left(1-|\psi(z)|^{2}\right)^{\alpha}} \rightarrow 0 & \text { as }|\varphi(z)| \wedge|\psi(z)| \rightarrow 1 . \tag{2.4}
\end{array}
$$

To prepare for the proof of this theorem we have to recall some notions related to weak compactness. A Banach space $X$ is said to have the Dunford-Pettis property if $x_{n}^{*}\left(x_{n}\right) \rightarrow 0$ whenever $x_{n} \rightarrow 0$ weakly in $X$ and $x_{n}^{*} \rightarrow 0$ weakly in the dual
space $X^{*}$. Equivalently, this means that every weakly compact linear operator from $X$ into some Banach space is completely continuous, i.e. maps weakly null sequences into norm-null sequences. A well-known example of a space with this property is $c_{0}$, the space of null sequences of scalars endowed with the supremum norm. For a survey of the Dunford-Pettis property we refer to [5].
The auxiliary functions provided by the next lemma will be used to construct appropriate weakly convergent test function sequences. Instead of this quite elementary lemma, one could utilize more refined results on interpolating functions here (see e.g. [7, VII.2]).

Lemma 2.2. Let $\left(a_{n}\right)$ be a sequence in $\mathbb{D}$ such that $a_{n} \rightarrow 1$. Then there exist numbers $0<\epsilon_{n}<1$ and $0<\delta_{n}<\delta_{n}^{\prime}<\pi$ and functions $Q_{n} \in H^{\infty}$ such that $\epsilon_{n} \rightarrow 0, \delta_{n}^{\prime} \rightarrow 0,\left\|Q_{n}\right\|_{\infty} \leq 1,\left|Q_{n}\left(a_{n}\right)\right| \geq 1 / 2$ and $\left|Q_{n}\left(e^{i t}\right)\right| \leq \epsilon_{n}$ when $|t| \leq \delta_{n}$ or $\delta_{n}^{\prime} \leq|t| \leq \pi$.

Proof. The functions $Q_{n}$ can be obtained as outer functions satisfying

$$
\log \left|Q_{n}(z)\right|=\frac{1}{2 \pi} \int_{-\pi}^{\pi} \frac{1-|z|^{2}}{\left|e^{i t}-z\right|^{2}} \log q_{n}(t) d t
$$

where $q_{n}(t)=1$ for $\delta_{n}<|t|<\delta_{n}^{\prime}$ and $q_{n}(t)=\epsilon_{n}$ otherwise. We leave it to the reader to check that the numbers $\epsilon_{n}, \delta_{n}$ and $\delta_{n}^{\prime}$ can be chosen in such a way that the requirements of the lemma are fulfilled.

One more lemma will be needed. It can be found in e.g. [10, Lem. 5.1], but we sketch the proof for completeness. Here and throughout the paper we will use the abbreviated notation $A \lesssim B$ to mean $A \leq C B$ for some inessential constant $C>0$ depending possibly on $\alpha$, and $A \sim B$ if $A \lesssim B \lesssim A$.

Lemma 2.3. For $f \in H_{\alpha}^{\infty}$ and $z, w \in \mathbb{D}$,

$$
\left|\left(1-|z|^{2}\right)^{\alpha} f(z)-\left(1-|w|^{2}\right)^{\alpha} f(w)\right| \lesssim\|f\|_{H_{\alpha}^{\infty}} \rho(z, w) .
$$

Proof. Assume $\|f\|_{H_{\alpha}^{\infty}} \leq 1$. Then the estimates $|f(\zeta)| \leq\left(1-|\zeta|^{2}\right)^{-\alpha}$ and $\left|f^{\prime}(\zeta)\right| \lesssim\left(1-|\zeta|^{2}\right)^{-\alpha-1}$ are valid for $\zeta \in \mathbb{D}$ (see e.g. [6, Thm. 5.5]). Write $h(\zeta)=\left(1-|\zeta|^{2}\right)^{\alpha} f(\zeta)$. One checks $\left|\nabla\left(1-|\zeta|^{2}\right)^{\alpha}\right| \lesssim\left(1-|\zeta|^{2}\right)^{\alpha-1}$ by a straightforward calculation. Then the product rule of differentiation gives the estimate $|\nabla h(\zeta)| \lesssim\left(1-|\zeta|^{2}\right)^{-1}$. Since $\left(1-|\zeta|^{2}\right)^{-1}|d \zeta|$ is the element of arc length in the hyperbolic metric, we have established the assertion of the lemma with the hyperbolic distance in place of the pseudo-hyperbolic one; that is,

$$
|h(z)-h(w)| \lesssim \log \frac{1+\rho(z, w)}{1-\rho(z, w)}
$$

To finish the proof, we consider two cases. If $\rho(z, w)<1 / 2$, routine estimates show that the logarithm is less than $3 \rho(z, w)$. If $\rho(z, w) \geq 1 / 2$, we just observe that since $|h|$ is bounded by 1 , we trivially have $|h(z)-h(w)| \leq 2 \leq 4 \rho(z, w)$.

Proof of Theorem 2.1. Necessity. Assume that $T$ is weakly compact. We first prove condition (2.2). Let $\left(z_{n}\right)$ be a sequence of points in $\mathbb{D}$ such that $\left|\varphi\left(z_{n}\right)\right| \rightarrow 1$. By passing to a subsequence and applying a rotation argument we may assume that $\varphi\left(z_{n}\right) \rightarrow 1$. Let $\left(Q_{n}\right)$ be the sequence of functions provided by Lemma 2.2 with respect to the points $\left(\varphi\left(z_{n}\right)\right)$. By passing to a further subsequence we may assume that the quantities of the lemma satisfy $\epsilon_{n} \leq 2^{-n}$ and $\delta_{n+1}^{\prime} \leq \delta_{n}$ for all $n$. Now define

$$
f_{n}(z)=\frac{Q_{n}(z)}{\left(1-\overline{\varphi\left(z_{n}\right)} z\right)^{\alpha}} \frac{z-\psi\left(z_{n}\right)}{1-\overline{\psi\left(z_{n}\right)} z}
$$

Then $\left|f_{n}(z)\right| \leq\left|Q_{n}(z)\right| /(1-|z|)^{\alpha}$. Since the sets $\left\{e^{i t}:\left|Q_{n}\left(e^{i t}\right)\right|>\epsilon_{n}\right\}$ are pairwise disjoint and $\sum_{n} \epsilon_{n} \leq 1$, it is easy to see that the map $\left(\xi_{n}\right) \mapsto \sum_{n} \xi_{n} f_{n}$ takes the sequence space $c_{0}$ continuously into $H_{\alpha}^{\infty}$. Composing this with $T$, we obtain a weakly compact operator from $c_{0}$ into $H_{\beta}^{\infty}$ such that the standard basis vectors $e_{n}$ in $c_{0}$ are sent to $T f_{n}$. Since $e_{n} \rightarrow 0$ weakly, the Dunford-Pettis property of $c_{0}$ yields that $\left\|T f_{n}\right\|_{H_{\beta}^{\infty}} \rightarrow 0$. However, by the definition of $f_{n}$ and the fact that $\left|Q_{n}\left(\varphi\left(z_{n}\right)\right)\right| \geq 1 / 2$ we have

$$
\left\|T f_{n}\right\|_{H_{\beta}^{\infty}} \geq\left(1-\left|z_{n}\right|^{2}\right)^{\beta}\left|T f_{n}\left(z_{n}\right)\right| \geq \frac{1}{2} \frac{\left(1-\left|z_{n}\right|^{2}\right)^{\beta}\left|u\left(z_{n}\right)\right|}{\left(1-\left|\varphi\left(z_{n}\right)\right|^{2}\right)^{\alpha}} \rho\left(z_{n}\right),
$$

so the right-hand side here must converge to zero. This proves (2.2), and (2.3) is analogous.
For the proof of (2.4) we begin with any sequence $\left(z_{n}\right)$ for which $\left|\varphi\left(z_{n}\right)\right| \rightarrow 1$ and $\left|\psi\left(z_{n}\right)\right| \rightarrow 1$. Again we may assume $\varphi\left(z_{n}\right) \rightarrow 1$ and in view of (2.2) and (2.3) also that $\rho\left(z_{n}\right) \rightarrow 0$. We then proceed as above, choosing functions $Q_{n}$ corresponding to the sequence $\left(\varphi\left(z_{n}\right)\right)$ by Lemma 2.2, passing to a subsequence, and defining test functions

$$
g_{n}(z)=\frac{Q_{n}(z)}{\left(1-\overline{\varphi\left(z_{n}\right)} z\right)^{\alpha}} .
$$

As previously, we deduce that $\left\|T g_{n}\right\|_{H_{\beta}^{\infty}} \rightarrow 0$. Now we have the estimate

$$
\begin{aligned}
\left\|T g_{n}\right\|_{H_{\beta}^{\infty}} & \geq\left(1-\left|z_{n}\right|^{2}\right)^{\beta}\left|T g_{n}\left(z_{n}\right)\right| \\
& =\left|\frac{\left(1-\left|z_{n}\right|^{2}\right)^{\beta} u\left(z_{n}\right) Q_{n}\left(\varphi\left(z_{n}\right)\right)}{\left(1-\left|\varphi\left(z_{n}\right)\right|^{2}\right)^{\alpha}}-\frac{\left(1-\left|z_{n}\right|^{2}\right)^{\beta} v\left(z_{n}\right) Q_{n}\left(\psi\left(z_{n}\right)\right)}{\left(1-\overline{\varphi\left(z_{n}\right)} \psi\left(z_{n}\right)\right)^{\alpha}}\right| .
\end{aligned}
$$

On the other hand, we have

$$
\begin{aligned}
& \left|\frac{\left(1-\left|z_{n}\right|^{2}\right)^{\beta} v\left(z_{n}\right) Q_{n}\left(\varphi\left(z_{n}\right)\right)}{\left(1-\left|\psi\left(z_{n}\right)\right|^{2}\right)^{\alpha}}-\frac{\left(1-\left|z_{n}\right|^{2}\right)^{\beta} v\left(z_{n}\right) Q_{n}\left(\psi\left(z_{n}\right)\right)}{\left(1-\overline{\varphi\left(z_{n}\right)} \psi\left(z_{n}\right)\right)^{\alpha}}\right| \\
& \quad=\frac{\left(1-\left|z_{n}\right|^{2}\right)^{\beta}\left|v\left(z_{n}\right)\right|}{\left(1-\left|\psi\left(z_{n}\right)\right|^{2}\right)^{\alpha}}\left|\left(1-\left|\varphi\left(z_{n}\right)\right|^{2}\right)^{\alpha} g_{n}\left(\varphi\left(z_{n}\right)\right)-\left(1-\left|\psi\left(z_{n}\right)\right|^{2}\right)^{\alpha} g_{n}\left(\psi\left(z_{n}\right)\right)\right|,
\end{aligned}
$$

where the first factor stays bounded because $W_{\psi, v}$ is a bounded operator and the second factor converges to zero by Lemma 2.3. Putting these observations
together we conclude that the difference in (2.4) tends to zero along the sequence $\left(z_{n}\right)$. This completes the proof of the necessity part.
Sufficiency. We assume conditions (2.2)-2.4) and prove that $T$ is compact. As usual, let $\left(f_{n}\right)$ be a sequence in $H_{\alpha}^{\infty}$ such that $\left\|f_{n}\right\|_{H_{\infty}^{\infty}} \leq 1$ and $f_{n} \rightarrow 0$ uniformly on compact subsets of $\mathbb{D}$. We have to show that $\left\|T f_{n}\right\|_{H_{\beta}^{\infty}} \rightarrow 0$.
To begin with, we let $\epsilon>0$ and use (2.2)-(2.4) to find $r \in(0,1)$ large enough such that

$$
\begin{array}{ll}
\frac{\left(1-|z|^{2}\right)^{\beta}|u(z)|}{\left(1-|\varphi(z)|^{2}\right)^{\alpha}} \rho(z) \leq \epsilon & \text { when }|\varphi(z)|>r, \\
\frac{\left(1-|z|^{2}\right)^{\beta}|v(z)|}{\left(1-|\psi(z)|^{2}\right)^{\alpha}} \rho(z) \leq \epsilon & \text { when }|\psi(z)|>r \tag{2.6}
\end{array}
$$

$\left|\left(1-|\varphi(z)|^{2}\right)^{\alpha} \quad\left(1-|\psi(z)|^{2}\right)^{\alpha}\right| \leq \epsilon$. First of all, it is clear that
The rest of the argument is divided into a few cases. First of all, it is clear that for points $z$ with $|\varphi(z)| \leq r$ and $|\psi(z)| \leq r$, the quantity

$$
\left(1-|z|^{2}\right)^{\beta}\left|T f_{n}(z)\right|=\left(1-|z|^{2}\right)^{\beta}\left|f_{n}(\varphi(z)) u(z)-f_{n}(\psi(z)) v(z)\right|
$$

converges to zero uniformly. Then suppose that $|\psi(z)|>r$. We may write $\left(1-|z|^{2}\right)^{\beta}\left|T f_{n}(z)\right|=\left|A_{n}(z)+B_{n}(z)\right|$, where

$$
\begin{aligned}
& A_{n}(z)=\left[\frac{\left(1-|z|^{2}\right)^{\beta} u(z)}{\left(1-|\varphi(z)|^{2}\right)^{\alpha}}-\frac{\left(1-|z|^{2}\right)^{\beta} v(z)}{\left(1-|\psi(z)|^{2}\right)^{\alpha}}\right]\left(1-|\varphi(z)|^{2}\right)^{\alpha} f_{n}(\varphi(z)) \\
& B_{n}(z)=\frac{\left(1-|z|^{2}\right)^{\beta} v(z)}{\left(1-|\psi(z)|^{2}\right)^{\alpha}}\left[\left(1-|\varphi(z)|^{2}\right)^{\alpha} f_{n}(\varphi(z))-\left(1-|\psi(z)|^{2}\right)^{\alpha} f_{n}(\psi(z))\right]
\end{aligned}
$$

Here $\left|B_{n}(z)\right| \lesssim \epsilon$ by Lemma 2.3 and inequality (2.6). As regards $A_{n}(z)$, we observe that in the set where $|\varphi(z)| \leq r$ clearly $A_{n}(z) \rightarrow 0$ uniformly. On the other hand, if $|\varphi(z)|>r$, then (2.7) implies $\left|A_{n}(z)\right| \leq \epsilon$. Hence

$$
\limsup _{n \rightarrow \infty} \sup \left\{\left(1-|z|^{2}\right)^{\beta}\left|T f_{n}(z)\right|:|\psi(z)|>r\right\} \lesssim \epsilon .
$$

By symmetry considerations the same conclusion also holds in the set where $|\varphi(z)|>r$. Since $\epsilon$ was arbitrary, we deduce that $\left(1-|z|^{2}\right)^{\beta}\left|T f_{n}(z)\right| \rightarrow 0$ uniformly for $z \in \mathbb{D}$, and the proof of the sufficiency part is complete.

## 3. The Bloch case

In this section we consider the difference operator $T=C_{\varphi}-C_{\psi}$ as acting on the classical Bloch space $\mathcal{B}$. Note that $\varphi$ and $\psi$ can be any analytic self-maps of $\mathbb{D}$ because it follows from the Schwarz-Pick lemma that every composition operator is bounded on $\mathcal{B}$.

The following result is a corollary to Theorem 2.1 and the similarity argument explained before the statement of the theorem. It was obtained earlier by Hosokawa and Ohno [14, 15] (in a slightly different formulation).

Theorem 3.1 (Hosokawa-Ohno). $T$ is (weakly) compact on $\mathcal{B}$ if and only if

$$
\begin{align*}
\mathcal{D} \varphi(z) \rho(z) & \rightarrow 0 & \text { as }|\varphi(z)| & \rightarrow 1  \tag{B1}\\
\mathcal{D} \psi(z) \rho(z) & \rightarrow 0 & \text { as }|\psi(z)| & \rightarrow 1  \tag{B2}\\
\mathcal{D} \varphi(z)-\mathcal{D} \psi(z) & \rightarrow 0 & \text { as }|\varphi(z)| & \wedge|\psi(z)| \rightarrow 1 \tag{B3}
\end{align*}
$$

It turns out, however, that condition ( $\overline{\mathrm{B} 3}$ ) is implied by (B1) and (B2). Thus it can be dispensed with and we obtain Theorem 1.1, which we restate here.
Theorem 3.2. $T$ is (weakly) compact on $\mathcal{B}$ if and only if (B1) and (B2) hold.
The proof of our result is based on a pair of rather elementary lemmas concerning continuity properties of hyperbolic derivatives. The first lemma is a special case of [8, Thm. 6], and we skip its proof. (See also Remark 4.7 at the end of Section 4.)

Lemma 3.3. Let $\varphi: \mathbb{D} \rightarrow \mathbb{D}$ be an analytic map. Then

$$
|\mathcal{D} \varphi(z)-\mathcal{D} \varphi(w)| \lesssim \rho(z, w)
$$

for all $z, w \in \mathbb{D}$.
Lemma 3.4. Let $\varphi, \psi: \mathbb{D} \rightarrow \mathbb{D}$ be analytic maps. Then

$$
|\mathcal{D} \varphi(z)-\mathcal{D} \psi(z)| \lesssim \frac{1}{r} \sup \{\rho(w): \rho(z, w) \leq r\}
$$

for all $0<r<1$ and $z \in \mathbb{D}$.
Proof. Let $\sigma_{w}(z)=(w-z) /(1-\bar{w} z)$, so that $\sigma_{w}$ is the conformal automorphism of $\mathbb{D}$ that interchanges 0 and $w$. We begin by establishing the general inequality

$$
\begin{equation*}
\left|\sigma_{w}(z)-\sigma_{w^{\prime}}\left(z^{\prime}\right)\right| \lesssim \rho\left(z, z^{\prime}\right)+\rho\left(w, w^{\prime}\right) \tag{3.1}
\end{equation*}
$$

which holds for all points $z, z^{\prime}, w, w^{\prime} \in \mathbb{D}$ uniformly. To verify this, first note that $\left|\sigma_{w}(z)-\sigma_{w}\left(z^{\prime}\right)\right| \lesssim \rho\left(z, z^{\prime}\right)$ by the conformal invariance of the pseudo-hyperbolic distance. Since $\partial_{w} \sigma_{w}(z)=1 /(1-\bar{w} z)$ and $\partial_{\bar{w}} \sigma_{w}(z)=\sigma_{w}(z) \cdot z /(1-\bar{w} z)$ are both less than $1 /(1-|w|)$ in modulus, we may argue as in the proof of Lemma 2.3 to get $\left|\sigma_{w}(z)-\sigma_{w^{\prime}}(z)\right| \lesssim \rho\left(w, w^{\prime}\right)$. These observations, along with an application of the triangle inequality, yield (3.1).
To proceed to the actual proof, we note that for $z \in \mathbb{D}$ the derivative of $\sigma_{\varphi(z)} \circ \varphi \circ \sigma_{z}$ at the origin equals $\mathcal{D} \varphi(z)$. Therefore, if $0<r<1$ is given, the Cauchy integral formula for derivatives yields the representation

$$
\mathcal{D} \varphi(z)=\frac{1}{2 \pi i} \int_{|\zeta|=r} \frac{\left(\sigma_{\varphi(z)} \circ \varphi \circ \sigma_{z}\right)(\zeta)}{\zeta^{2}} d \zeta
$$

An analogous formula holds for $\mathcal{D} \psi(z)$. Now we can apply (3.1) to get the estimate

$$
\left|\left(\sigma_{\varphi(z)} \circ \varphi \circ \sigma_{z}\right)(\zeta)-\left(\sigma_{\psi(z)} \circ \psi \circ \sigma_{z}\right)(\zeta)\right| \lesssim \rho\left(\sigma_{z}(\zeta)\right)+\rho(z)
$$

As $\zeta$ traverses the set $|\zeta|=r$, the point $w=\sigma_{z}(\zeta)$ runs through the pseudohyperbolic circle $\rho(z, w)=r$. Thus, denoting the supremum in the statement of the lemma by $S$, we arrive at the estimate

$$
|\mathcal{D} \varphi(z)-\mathcal{D} \psi(z)| \lesssim \frac{1}{2 \pi} \int_{|\zeta|=r} \frac{S}{r^{2}}|d \zeta|=\frac{S}{r},
$$

and the proof is complete.
Proof of Theorem 3.2. We assume that conditions (B1) and (B2) of Theorem 3.1 hold, and we will prove that then ( $\overline{\mathrm{B} 3)}$ is necessarily satisfied. Suppose $\left(z_{n}\right)$ is a sequence in $\mathbb{D}$ for which $\left|\varphi\left(z_{n}\right)\right| \rightarrow 1$ and $\left|\psi\left(z_{n}\right)\right| \rightarrow 1$. We wish to show that $\mathcal{D} \varphi\left(z_{n}\right)-\mathcal{D} \psi\left(z_{n}\right) \rightarrow 0$.
Assume to the contrary that $\left|\mathcal{D} \varphi\left(z_{n}\right)-\mathcal{D} \psi\left(z_{n}\right)\right| \geq 2 \epsilon$ for some $\epsilon>0$. By Lemma 3.3 there exists $r \in(0,1)$ such that

$$
\epsilon \leq\left|\mathcal{D} \varphi\left(z_{n}\right)-\mathcal{D} \psi\left(z_{n}\right)\right|-\epsilon \leq|\mathcal{D} \varphi(w)-\mathcal{D} \psi(w)|
$$

whenever $\rho\left(z_{n}, w\right) \leq r$. On the other hand, by Lemma 3.4 we can find points $w_{n} \in \mathbb{D}$ with $\rho\left(z_{n}, w_{n}\right) \leq r$ such that $2 \epsilon \leq\left|\mathcal{D} \varphi\left(z_{n}\right)-\overline{\mathcal{D} \psi}\left(z_{n}\right)\right| \lesssim \rho\left(w_{n}\right)$. On multiplying these two inequalities together we get

$$
\begin{equation*}
2 \epsilon^{2} \lesssim\left|\mathcal{D} \varphi\left(w_{n}\right)-\mathcal{D} \psi\left(w_{n}\right)\right| \rho\left(w_{n}\right) \tag{3.2}
\end{equation*}
$$

for all $n$. Since $\rho\left(\varphi\left(z_{n}\right), \varphi\left(w_{n}\right)\right) \leq \rho\left(z_{n}, w_{n}\right) \leq r$, we necessarily have $\left|\varphi\left(w_{n}\right)\right| \rightarrow 1$. Similarly $\left|\psi\left(w_{n}\right)\right| \rightarrow 1$. Hence conditions ( $\overline{\mathrm{B} 1)}$ and (B2) imply that the righthand side of (3.2) tends to zero. This is a contradiction and completes the proof.

## 4. The Lipschitz case

When applied to differences of composition operators on the Lipschitz spaces $\mathcal{B}^{\alpha}$, where $0<\alpha<1$, Theorem 2.1 yields Theorem 1.2, which we restate here.

Theorem 4.1. Let $0<\alpha<1$ and assume that $\varphi, \psi: \mathbb{D} \rightarrow \mathbb{D}$ are analytic maps with $\left\|\mathcal{D}^{\alpha} \varphi\right\|_{\infty}<\infty$ and $\left\|\mathcal{D}^{\alpha} \psi\right\|_{\infty}<\infty$. Then $T=C_{\varphi}-C_{\psi}$ is (weakly) compact on $\mathcal{B}^{\alpha}$ if and only if

$$
\begin{align*}
\mathcal{D}^{\alpha} \varphi(z) \rho(z) & \rightarrow 0 & \text { as }|\varphi(z)| \rightarrow 1,  \tag{L1}\\
\mathcal{D}^{\alpha} \psi(z) \rho(z) & \rightarrow 0 & \text { as }|\psi(z)| \rightarrow 1  \tag{L2}\\
\mathcal{D}^{\alpha} \varphi(z)-\mathcal{D}^{\alpha} \psi(z) & \rightarrow 0 & \text { as }|\varphi(z)| \wedge|\psi(z)| \rightarrow 1 \tag{L3}
\end{align*}
$$

We first point out some implications of the theorem. Let us recall here that all functions in $\mathcal{B}^{\alpha}$, hence $\varphi$ and $\psi$, extend continuously to the closed disc $\overline{\mathbb{D}}$. Assume for the moment that $\zeta \in \partial \mathbb{D}$ is a point for which $|\varphi(\zeta)|=1$. Then it is known that $\varphi$ has a finite angular derivative at $\zeta$, say $\varphi^{\prime}(\zeta)=\delta$, and therefore $\mathcal{D}^{\alpha} \varphi(z) \rightarrow \delta /|\delta|^{\alpha}$ as $z \rightarrow \zeta$ non-tangentially (see Section5). So, if (L1) holds, we actually have $\rho(z) \rightarrow 0$ as $z \rightarrow \zeta$ non-tangentially. In particular, then $\psi(\zeta)=\varphi(\zeta)$, and with the aid of ( $\overline{\mathrm{L} 3)}$ we further obtain $\psi^{\prime}(\zeta)=\varphi^{\prime}(\zeta)$. Thus a necessary condition for the (weak) compactness of $T$ on $\mathcal{B}^{\alpha}$ is that the symbols $\varphi$ and $\psi$ have the same unimodular boundary values and that their angular derivatives at those boundary points coincide. This condition is known to be necessary for the compactness of $T$ on many other spaces as well, including the Hardy space $H^{2}$ (see [17] or [4, Thm. 9.16]) and the Bloch space $\mathcal{B}$ (see [30, Sec. 4.7]).
The above reasoning leads to an interesting question, which we have been unable to answer.

Question 4.2. Let $0<\alpha<1$ and suppose $\left\|\mathcal{D}^{\alpha} \varphi\right\|_{\infty}<\infty$ and $\left\|\mathcal{D}^{\alpha} \psi\right\|_{\infty}<\infty$. If $T$ is compact on $\mathcal{B}^{\alpha}$, does it follow that $\rho(z) \rightarrow 0$ as $|\varphi(z)| \vee|\psi(z)| \rightarrow 1$ ?

We observed above that a non-tangential version of this holds true. If the answer to the general question were positive, then the (weak) compactness of $T$ would be characterized by the stated condition together with condition (L3), so Theorem 4.1 could be simplified considerably. Let us recall here that the answer to Question 4.2 is positive in the larger space $H^{\infty}$ of bounded analytic functions [18.
We proceed to give a simple family of examples to illustrate the application of Theorem 4.1. It will be convenient to employ $\varphi(z)=(1+z) / 2$ as a kind of reference map from which we can build other maps with desired properties. We will make repeated use of the identity

$$
\begin{equation*}
1-|\varphi(z)|^{2}=\frac{1}{2}\left(1-|z|^{2}\right)+\frac{1}{4}|z-1|^{2}, \tag{4.1}
\end{equation*}
$$

which can be verified by a direct calculation.
Example 4.3. Let $\varphi$ be as above and put

$$
\psi=\varphi+\lambda, \quad \text { where } \quad \lambda(z)=c_{p}(z-1)^{p}, p \geq 2 .
$$

Here $c_{p}>0$ is chosen small enough in order that $\overline{\psi(\mathbb{D})} \subset \mathbb{D} \cup\{1\}$. For instance, if $c_{p}=2^{-p-2}$, then $|\lambda(z)| \leq|z-1|^{2} / 16$ and hence $1-|\psi| \geq 1-|\varphi|-|\lambda| \geq(1-|\varphi|) / 2$. Also note that since $\varphi^{\prime}$ and $\lambda^{\prime}$ are bounded in $\mathbb{D}$, both $\varphi$ and $\psi$ induce bounded composition operators on $\mathcal{B}^{\alpha}$.
Case $p>2$. By virtue of the estimate

$$
\rho(z) \leq \frac{|\lambda(z)|}{1-|\varphi(z)|} \lesssim \frac{|z-1|^{p}}{|z-1|^{2}}=|z-1|^{p-2}
$$

we obviously have $\rho(z) \rightarrow 0$ as $z \rightarrow 1$. Thus (L1) and (L2) are satisfied. To address (L3) we observe that, by (4.1) and the definition of $\lambda$, the ratio of $1-$ $|\varphi(z)|$ and $1-|\psi(z)|$ tends to 1 as $z \rightarrow 1$. Since $\lambda^{\prime}(z)=p(z-1)^{p-1} \rightarrow 0$, it follows rather easily that (L3) is satisfied too. So $T=C_{\varphi}-C_{\psi}$ is compact in this case.
Case $p=2$. Now it is easily seen that $|1-\varphi(z) \overline{\psi(z)}| \sim 1-|z|^{2}+|z-1|^{2}$ and hence

$$
\rho(z) \sim \frac{|z-1|^{2}}{1-|z|^{2}+|z-1|^{2}}=\left(1+\frac{1-|z|^{2}}{|z-1|^{2}}\right)^{-1} .
$$

On the other hand,

$$
\left|\mathcal{D}^{\alpha} \varphi(z)\right| \sim \frac{\left(1-|z|^{2}\right)^{\alpha}}{\left(1-|z|^{2}+|z-1|^{2}\right)^{\alpha}}=\left(1+\frac{|z-1|^{2}}{1-|z|^{2}}\right)^{-\alpha}
$$

As a consequence we see that the limiting behaviour of $\rho(z)$ and $\left|\mathcal{D}^{\alpha} \varphi(z)\right|$ as $z \rightarrow 1$ depends strongly on the path of approach. Indeed, if $\left(1-|z|^{2}\right) /|z-1|^{2}$ tends to zero or infinity (e.g. if $z \rightarrow 1$ non-tangentially), then one of these quantities converges to zero and the other is $\sim 1$, so $\mathcal{D}^{\alpha} \varphi(z) \rho(z) \rightarrow 0$ in this case. But if $\left(1-|z|^{2}\right) /|z-1|^{2}$ tends to a positive constant (e.g. if $z \rightarrow 1$ along a circle that touches $\partial \mathbb{D}$ at 1 ), then $\left|\mathcal{D}^{\alpha} \varphi(z)\right| \rho(z) \sim 1$. Therefore (L1) fails and $T$ is non-compact.

The preceding examples leave open the natural question whether condition (L3) could be dispensed with in Theorem 4.1, as it was possible to do in the Bloch case in Section 3. We conclude the present section by giving a negative answer to this question. We will again start from the map $\varphi(z)=(1+z) / 2$, but the procedure used to construct the other map $\psi$ will be somewhat complicated and will require careful analysis of the growth properties of $\mathcal{D}^{\alpha}$-derivatives.
Theorem 4.4. Let $\varphi$ be as above and $0<\alpha<1$. There is a map $\psi$, analytic on $\mathbb{D}$, with the following properties:
(i) $\overline{\psi(\mathbb{D})} \subset \mathbb{D} \cup\{1\}$ and $\psi(1)=1$,
(ii) $\left\|\mathcal{D}^{\alpha} \psi\right\|_{\infty}<\infty$,
(iii) $\rho(z) \rightarrow 0$ as $z \rightarrow 1$, and
(iv) $\mathcal{D}^{\alpha} \varphi(z)-\mathcal{D}^{\alpha} \psi(z) \nrightarrow 0$ as $z \rightarrow 1$.

In particular, conditions (L1) and (L2) of Theorem 4.1 are satisfied but (L3) fails.

Before we start with the actual proof of this theorem, we lay out some preliminaries. We will make use of auxiliary functions $\kappa_{a}$ and $\lambda_{a}$ defined on $\mathbb{D}$ by

$$
\begin{aligned}
& \kappa_{a}(z)=\frac{1-|a|}{1-\bar{a} z} \\
& \lambda_{a}(z)=(z-1)^{3} \kappa_{a}(z)
\end{aligned}
$$

and depending on a parameter $a \in \mathbb{D}$. Note that $\left|\kappa_{a}(z)\right| \leq 1$ and therefore $\left|\lambda_{a}(z)\right| \leq|z-1|^{3}$ for all $z \in \mathbb{D}$. In addition,

$$
\begin{aligned}
& \kappa_{a}^{\prime}(z)=\frac{\bar{a}(1-|a|)}{(1-\bar{a} z)^{2}} \\
& \lambda_{a}^{\prime}(z)=(z-1)^{3} \kappa_{a}^{\prime}(z)+3(z-1)^{2} \kappa_{a}(z)
\end{aligned}
$$

The intuitive idea behind our construction can be described as follows. We will employ functions $\lambda_{a}$ as elementary perturbations to the map $\varphi$. Adding $\lambda_{a}$ to $\varphi$ does not essentially alter the behaviour of the map near 1 in the hyperbolic scale. However, by a judicious choice of $a$ we can influence the $\mathcal{D}^{\alpha}$-derivative of the resulting map just in the right way (Lemma 4.5). We will also observe (Lemma 4.6) that each perturbation $\lambda_{a}$ is "local" in the sense that when $a$ is close to the boundary of $\mathbb{D}$, the support of $\lambda_{a}$ in the disc is essentially concentrated around the radius through point $a$. Thus it makes sense to define $\psi=\varphi+c \sum_{k} \lambda_{a_{k}}$ where $c>0$ is a small constant and $\left(a_{k}\right)$ is a certain sequence of points in $\mathbb{D}$ converging to 1 .
Lemma 4.5. There are constants $c_{1}, c_{2}>0$ and $q \in(1 / 2,1)$ depending only on $\alpha$ such that if $q<|a|<1$ and

$$
\begin{equation*}
1-|a|=|a-1|^{(3-2 \alpha) /(1-\alpha)}, \tag{4.2}
\end{equation*}
$$

then, for all $z \in \mathbb{D}$,

$$
\begin{equation*}
\left(\frac{1-|z|^{2}}{1-|\varphi(z)|^{2}}\right)^{\alpha}\left|\lambda_{a}^{\prime}(z)\right| \leq c_{1} \tag{4.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(\frac{1-|a|^{2}}{1-|\varphi(a)|^{2}}\right)^{\alpha}\left|\lambda_{a}^{\prime}(a)\right| \geq c_{2} . \tag{4.4}
\end{equation*}
$$

Proof. Let us write

$$
\begin{aligned}
& A_{a}(z)=\left(\frac{1-|z|^{2}}{1-|\varphi(z)|^{2}}\right)^{\alpha}(z-1)^{3} \kappa_{a}^{\prime}(z) \\
& B_{a}(z)=\left(\frac{1-|z|^{2}}{1-|\varphi(z)|^{2}}\right)^{\alpha}(z-1)^{2} \kappa_{a}(z)
\end{aligned}
$$

so that the expression on the left-hand side of (4.3) equals $\left|A_{a}(z)+3 B_{a}(z)\right|$.
We first prove (4.3) by showing that both $A_{a}$ and $B_{a}$ are uniformly bounded by a constant independent of $a$. Since $1-|\varphi(z)|^{2} \gtrsim|z-1|^{2}$ and $\left|\kappa_{a}^{\prime}(z)\right| \leq 1 /|1-\bar{a} z|$, we get

$$
\begin{equation*}
\left|A_{a}(z)\right| \lesssim \frac{\left(1-|z|^{2}\right)^{\alpha}|z-1|^{3}}{|z-1|^{2 \alpha}|1-\bar{a} z|} \lesssim \frac{|z-1|^{3-2 \alpha}}{|1-\bar{a} z|^{1-\alpha}} \tag{4.5}
\end{equation*}
$$

If $|z-1| \leq 2|a-1|$, this is $\lesssim|a-1|^{3-2 \alpha} /(1-|a|)^{1-\alpha}$, which is a constant by (4.2). If $|z-1|>2|a-1|$, then $|1-\bar{a} z| \geq|z-1|-|a-1| \gtrsim|z-1|$ and $A_{a}(z)$
is uniformly bounded also in this case. With regard to $B_{a}$, we use the simple estimates $1-|\varphi(z)|^{2} \gtrsim 1-|z|^{2}$ and $\left|\kappa_{a}(z)\right| \leq 1$ to get $\left|B_{a}(z)\right| \lesssim|z-1|^{2} \lesssim 1$. This completes the proof of the upper estimate 4.3).
To establish the lower estimate (4.4) we first observe that (4.1) and (4.2) imply $1-|\varphi(a)|^{2} \lesssim|a-1|^{2}$. In addition, $\left|\kappa_{a}^{\prime}(a)\right| \gtrsim 1 /(1-|a|)$. Hence

$$
\left|A_{a}(a)\right| \gtrsim \frac{(1-|a|)^{\alpha}|a-1|^{3}}{|a-1|^{2 \alpha}(1-|a|)}=\frac{|a-1|^{3-2 \alpha}}{(1-|a|)^{1-\alpha}}=1
$$

again by (4.2). Since $\left|B_{a}(a)\right| \lesssim|a-1|^{2}$, which tends to zero as $a \rightarrow 1$ (equivalently $|a| \rightarrow 1$ ), we conclude that (4.4) holds when $|a|$ is sufficiently close to 1 .

Lemma 4.6. Assume that $a \in \mathbb{D}$ satisfies (4.2). For every $\epsilon>0$, there exists $\delta>0$ such that if $\theta=\arg a \in(0, \delta)$, then $\left|\kappa_{a}(z)\right| \leq \epsilon$ and $\left|\kappa_{a}^{\prime}(z)\right| \leq \epsilon$ whenever $z \in \mathbb{D}$ such that $\arg z \in[0,2 \pi] \backslash(\theta / 2,3 \theta / 2)$.

Proof. Write $z=r e^{i t}$ so that $t=\arg z$. In view of the expressions given for $\kappa_{a}$ and $\kappa_{a}^{\prime}$ after the statement of Theorem 4.4, it suffices to show that the quotient

$$
\begin{equation*}
\frac{1-|a|}{\left|1-\bar{a} r e^{i t}\right|^{2}}=\frac{|a-1|^{(3-2 \alpha) /(1-\alpha)}}{\left|1-\bar{a} r e^{i t}\right|^{2}} \tag{4.6}
\end{equation*}
$$

can be made arbitrarily small for $\theta$ and $z=r e^{i t}$ as specified in the lemma. In the sequel we may assume $r \geq 1 / 2$; otherwise we would have $\left|1-\bar{a} r e^{i t}\right|^{2} \geq 1 / 4$ for all $a$ and $t$, yielding the claim immediately as $\theta \rightarrow 0+$ (or equivalently $a \rightarrow 1$ ).
Let us first consider the denominator of (4.6). Note that

$$
\left|1-\bar{a} r e^{i t}\right|^{2}=1+|a|^{2} r^{2}-2|a| r \cos (t-\theta) .
$$

Here $\cos (t-\theta)$ is at its maximum when $|t-\theta|$ is the smallest possible, i.e. equals $\theta / 2$. Moreover, we have the elementary estimate $\cos (\theta / 2) \leq 1-c \theta^{2}$ for some $c>0$. Thus

$$
\left|1-\bar{a} r e^{i t}\right|^{2} \geq(1-|a| r)^{2}+2|a| r c \theta^{2} \geq(1-|a|)^{2}+c|a| \theta^{2}
$$

The numerator of (4.6) can be estimated in the same way. Since $\cos \theta \geq 1-\theta^{2} / 2$, we have

$$
|a-1|^{2}=1+|a|^{2}-2|a| \cos \theta \leq(1-|a|)^{2}+|a| \theta^{2} .
$$

These estimates combine to show that $|a-1|^{2} \lesssim\left|1-\bar{a} r e^{i t}\right|^{2}$. Since the exponent $(3-2 \alpha) /(1-\alpha)$ in the numerator of $(4.6)$ is greater than 2 , it follows that the whole quotient converges to zero as $\theta \rightarrow 0+$ (or $a \rightarrow 1$ ), the convergence being uniform in $r$ and $t$. This completes the proof.

Proof of Theorem 4.4. To begin with, we employ Lemma 4.6 inductively to find a sequence ( $a_{k}$ ) in $\mathbb{D}$, approaching point 1 along the curve (4.2), such that if $\theta_{k}=\arg a_{k}$, then $0<\theta_{k+1} \leq \theta_{k} / 3$ for every $k$ and

$$
\begin{equation*}
\left|\kappa_{a_{k}}(z)\right| \leq 2^{-k}, \quad\left|\kappa_{a_{k}}^{\prime}(z)\right| \leq 2^{-k} \quad \text { if } \arg z \in[0,2 \pi] \backslash\left(\theta_{k} / 2,3 \theta_{k} / 2\right) \tag{4.7}
\end{equation*}
$$

Since the intervals $\left(\theta_{k} / 2,3 \theta_{k} / 2\right)$ are disjoint, inequalities (4.7) are certainly satisfied at every point $z$ of $\mathbb{D}$ for all indices $k$ with the possible exception of one $k$ (depending on $z$ ). For this exceptional $k$ we nevertheless have the trivial bound $\left|\kappa_{a_{k}}(z)\right| \leq 1$.
We may clearly assume that $\left|a_{1}\right|$, and hence each $\left|a_{k}\right|$, is greater than the number $q$ of Lemma 4.5. Let

$$
\lambda(z)=\frac{1}{64} \sum_{k=1}^{\infty} \lambda_{a_{k}}(z)=\frac{(z-1)^{3}}{64} \sum_{k=1}^{\infty} \kappa_{a_{k}}(z) .
$$

By the remarks above we see that $\lambda$ is a well-defined analytic function in $\mathbb{D}$ (with continuous extension to $\overline{\mathbb{D}}$ ) and

$$
|\lambda(z)| \leq \frac{1}{32}|z-1|^{3} \leq \frac{1}{16}|z-1|^{2} .
$$

Put $\psi=\varphi+\lambda$. Since $1-|\varphi(z)| \geq|z-1|^{2} / 8$, we have $1-|\psi(z)| \geq(1-|\varphi(z)|) / 2$, so $\psi$ is an analytic function satisfying requirement (i) of the theorem. Moreover, we may estimate

$$
\rho(z) \leq \frac{|\lambda(z)|}{1-|\varphi(z)|-|\lambda(z)|} \leq \frac{|z-1|^{3} / 32}{|z-1|^{2} / 16}=\frac{1}{2}|z-1|,
$$

from which (iiii) obtains.
It remains to verify (iii) and (iv). The preceding observations imply that $1-|\varphi(z)|$ is comparable to $1-|\psi(z)|$ and their ratio tends to one as $z \rightarrow 1$. Therefore it is enough to show that the expression

$$
\left(\frac{1-|z|}{1-|\varphi(z)|}\right)^{\alpha}\left|\lambda^{\prime}(z)\right|
$$

stays bounded in $\mathbb{D}$ and does not converge to zero as $z \rightarrow 1$. To accomplish this we observe that by the definition of $\lambda_{a_{k}}$ and inequalities (4.7) we have $\left|\lambda_{a_{k}}^{\prime}(z)\right| \leq 2^{-k} \cdot 5|z-1|^{2}$ for all $z \in \mathbb{D}$ and all except at most one $k$. The first claim follows from this and the first part of Lemma 4.5 (applied to the exceptional $\lambda_{a_{k}}$ ). To verify the second claim we apply the second part of Lemma 4.5 to conclude that the above expression does not converge to zero as we approach point 1 along the sequence $\left(a_{k}\right)$.

Remark 4.7. The argument presented in Section 3 to get rid of condition ( $\overline{\mathrm{B} 3}$ ) in Theorem 3.1 fails in the context of Lipschitz spaces because there is no counterpart of Lemma 3.4 for general $\mathcal{D}^{\alpha}$-derivatives. However, we note that Lemma 3.3 can be carried over to the Lipschitz case; namely, for any $\alpha>0$ one has

$$
\left|\mathcal{D}^{\alpha} \varphi(z)-\mathcal{D}^{\alpha} \varphi(w)\right| \lesssim\left\|\mathcal{D}^{\alpha} \varphi\right\|_{\infty} \rho(z, w) .
$$

This can be deduced from the generalized Schwarz-Pick estimates obtained in [19]. In fact, Theorem 3 (and its proof) in [19] shows that

$$
\frac{\left(1-|z|^{2}\right)^{\alpha+1}}{\left(1-|\varphi(z)|^{2}\right)^{\alpha}}\left|\varphi^{\prime \prime}(z)\right| \lesssim\left\|\mathcal{D}^{\alpha} \varphi\right\|_{\infty}
$$

and by applying the product rule of differentiation (cf. the proof of Lemma 2.3) we get $\left|\nabla \mathcal{D}^{\alpha} \varphi(z)\right| \lesssim\left\|\mathcal{D}^{\alpha} \varphi\right\|_{\infty} /\left(1-|z|^{2}\right)$, which then yields the desired estimate.

## 5. Composition operators on Lipschitz spaces revisited

Starting from the early 1980s, the fundamental problems of boundedness and compactness for a single composition operator on the analytic Lipschitz spaces have been studied by many authors using different approaches. In this last section we briefly revisit this theory and address a couple of natural questions that arise from the existing literature. We assume throughout that $\varphi$ is an analytic self-map of the unit disc and $0<\alpha<1$.
An early contribution in this area was due to Roan [25]. In his Corollary 1 the following result on the boundedness of $C_{\varphi}$ is given:

- $C_{\varphi}$ is bounded on $\mathcal{B}^{\alpha}$ if and only if $\varphi \in \mathcal{B}^{\alpha}$ and there exist $M<\infty$ and $r<1$ such that $\left|\varphi^{\prime}(z)\right| \leq M$ whenever $|\varphi(z)| \geq r$.
Unfortunately, as noticed by Cowen and MacCluer [4, p. 196], there is an error in Roan's proof for the necessity of his condition. Thus Cowen and MacCluer mention it as an open question whether the result still holds. As a by-product of the work done in Section 4 we can give a negative answer to their question: There are functions that fail Roan's condition but nonetheless induce a bounded composition operator on $\mathcal{B}^{\alpha}$.

Example 5.1. Let $\psi=\varphi+c \sum_{k} \lambda_{a_{k}}$ be the function constructed in the proof of Theorem 4.4. Then $a_{k} \rightarrow 1$ and $\psi\left(a_{k}\right) \rightarrow 1$ as $k \rightarrow \infty$. Consider the derivative of $\psi$ at $a_{k}$. By the second part of Lemma 4.5 plus equations (4.1) and (4.2) we have

$$
\left|\lambda_{a_{k}}^{\prime}\left(a_{k}\right)\right| \gtrsim\left(\frac{\left|a_{k}-1\right|^{2}}{1-\left|a_{k}\right|^{2}}\right)^{\alpha} \gtrsim\left|a_{k}-1\right|^{-\alpha /(1-\alpha)}
$$

so $\left|\lambda_{a_{k}}^{\prime}\left(a_{k}\right)\right| \rightarrow \infty$ as $k \rightarrow \infty$. Arguing as at the end of the proof of Theorem4.4 we now see that $\left|\psi^{\prime}\left(a_{k}\right)\right| \rightarrow \infty$.

Let us now make the standing assumption that $\left\|\mathcal{D}^{\alpha} \varphi\right\|_{\infty}<\infty$, so that $C_{\varphi}$ is a bounded operator on $\mathcal{B}^{\alpha}$. For the compactness of $C_{\varphi}$ there are (at least) three different characterizations given in the literature. First of all, in the work cited above, Roan stated the following:

- $C_{\varphi}$ is compact on $\mathcal{B}^{\alpha}$ if and only if for every $\epsilon>0$ there exists $r<1$ such that $\left|\varphi^{\prime}(z)\right| \leq \epsilon$ whenever $|\varphi(z)| \geq r$.

Later Shapiro [28] investigated the compactness problem in a general setting of boundary-regular and conformally invariant "small" function spaces. By a spectral-theoretic argument he obtained the surprising result that a necessary condition for the compactness of $C_{\varphi}$ on such spaces is $\|\varphi\|_{\infty}<1$. In the Lipschitz case it follows almost trivially that his condition is also sufficient, thus yielding a complete characterization of compactness as follows:

- $C_{\varphi}$ is compact on $\mathcal{B}^{\alpha}$ if and only if $\|\varphi\|_{\infty}<1$.

Finally, it is certainly possible to characterize the compactness of $C_{\varphi}$ by an appropriate "little-oh" version of Madigan's [20] boundedness condition. That is:

- $C_{\varphi}$ is (weakly) compact on $\mathcal{B}^{\alpha}$ if and only if $\mathcal{D}^{\alpha} \varphi(z) \rightarrow 0$ as $|\varphi(z)| \rightarrow 1$.

This result, although not explicitly stated by Madigan, follows by fairly standard arguments from the basic identity $(1.1)$ and lends itself to many generalizations (see [3, 22, 32]). Of course, it could also be deduced from our Theorem 1.2 by taking $\psi \equiv 0$.
A natural question now arises: can one demonstrate the equivalence of these three compactness conditions by function-theoretic arguments, without invoking operator theory? Obviously, if Shapiro's condition holds, then the other two become trivial. Also, assuming the finiteness of $\left\|\mathcal{D}^{\alpha} \varphi\right\|_{\infty}$ (or only that $\varphi \in \mathcal{B}^{\alpha}$ ), a simple reasoning shows that Roan's compactness condition implies the $\mathcal{D}^{\alpha}{ }_{-}$ condition. However, there appears to be no known function-theoretic argument to infer Shapiro's condition from the $\mathcal{D}^{\alpha}$-condition.
Our aim is to give such an argument. The key to it is the notion of angular derivatives and the following proposition. We note that the proposition is already known (see [4, Cor. 4.10]), but the existing proof depends on the above-mentioned result of Shapiro. In what follows we will give a direct function-theoretic proof.

Proposition 5.2. Let $0<\alpha<1$ and suppose $C_{\varphi}$ is a bounded operator on $\mathcal{B}^{\alpha}$, that is, $\left\|\mathcal{D}^{\alpha} \varphi\right\|_{\infty}<\infty$. Then $\varphi$ has a finite angular derivative at every $\zeta \in \partial \mathbb{D}$ with $|\varphi(\zeta)|=1$.

Let us recall that an analytic map $\varphi: \mathbb{D} \rightarrow \mathbb{D}$ is said to have a finite angular derivative at $\zeta \in \partial \mathbb{D}$ if there exists a point $\omega \in \partial \mathbb{D}$ such that the difference quotient $(\varphi(z)-\omega) /(z-\zeta)$ tends to a finite limit as $z \rightarrow \zeta$ non-tangentially. The limit is denoted by $\varphi^{\prime}(\zeta)$ and called the angular derivative of $\varphi$ at $\zeta$. Clearly then $\varphi(\zeta)=\omega$ as a non-tangential limit.
The main result about angular derivatives is the following classical theorem. See, for example, [4, Thm. 2.44].

Theorem 5.3 (Julia-Carathéodory). For $\zeta \in \partial \mathbb{D}$ the following are equivalent:
(1) $\varphi$ has a finite angular derivative at $\zeta$;
(2) $\varphi$ has a non-tangential limit of modulus 1 at $\zeta$, and $\varphi^{\prime}$ has a finite nontangential limit at $\zeta$;
(3) the quantity $d(\zeta)=\liminf _{z \rightarrow \zeta}(1-|\varphi(z)|) /(1-|z|)$ is finite.

Furthermore, under these conditions the non-tangential limit of $\varphi^{\prime}$ at $\zeta$, the angular derivative $\varphi^{\prime}(\zeta)$ and the number $d(\zeta) \varphi(\zeta) \bar{\zeta}$ all agree and the limit inferior in (3) is a non-tangential limit.

Proof of Proposition 5.2. Assume $\varphi(1)=1$. We then claim that $\varphi$ has a finite angular derivative at 1 . Let us define, for $0<r<1$,

$$
h(r)=\left(\frac{1-r}{1-\varphi(r)}\right)^{\alpha} \varphi^{\prime}(r), \quad u(r)=\frac{1-\varphi(r)}{1-r} .
$$

The hypothesis of the proposition implies that $h$ is a bounded function, and in view of the Julia-Carathéodory theorem the claim will follow if we show that also $u$ is bounded.
Note that $\varphi^{\prime}(r)=-(1-r) u^{\prime}(r)+u(r)$ and so

$$
h(r)=u(r)^{-\alpha} \varphi^{\prime}(r)=-(1-r) u(r)^{-\alpha} u^{\prime}(r)+u(r)^{1-\alpha} .
$$

If we write $v(r)=u(r)^{1-\alpha}$, then this is equivalent to

$$
-\frac{1}{1-\alpha}(1-r) v^{\prime}(r)+v(r)=h(r) .
$$

The general solution of this differential equation is

$$
v(r)=-\frac{1-\alpha}{(1-r)^{1-\alpha}} \int_{1}^{r} \frac{h(s)}{(1-s)^{\alpha}} d s+\frac{C}{(1-r)^{1-\alpha}} .
$$

Since $h$ is bounded, the first term here is a bounded function of $r$. Moreover, the definition of $v$ implies that $v(r)$ is of the order $o\left(1 /(1-r)^{1-\alpha}\right)$ as $r \rightarrow 1-$, so we must have $C=0$. Hence $v$ and $u$ are bounded.

As a corollary we obtain the desired result that the "little-oh" condition for the $\mathcal{D}^{\alpha}$-derivative actually trivializes to Shapiro's compactness condition.

Corollary 5.4. Let $0<\alpha<1$ and suppose $\varphi \in \mathcal{B}^{\alpha}$ such that $\mathcal{D}^{\alpha} \varphi(z) \rightarrow 0$ as $|\varphi(z)| \rightarrow 1$. Then $\|\varphi\|_{\infty}<1$.

Proof. Assume to the contrary that $|\varphi(\zeta)|=1$ for some $\zeta \in \partial \mathbb{D}$. By Proposition $5.2 \varphi$ has a finite angular derivative, say $\delta$, at $\zeta$. But by the JuliaCarathéodory theorem $(1-|\varphi(z)|) /(1-|z|) \rightarrow|\delta|$ and $\varphi^{\prime}(z) \rightarrow \delta$ as $z \rightarrow \zeta$ non-tangentially. Hence $\left|\mathcal{D}^{\alpha} \varphi(z)\right| \rightarrow|\delta|^{1-\alpha}$, which is a contradiction.

Acknowledgement. The author thanks Eero Saksman for advice and helpful discussions and Hans-Olav Tylli for useful remarks.
