#### Abstract

: In this correspondence, we show that the problem of computing the complex roots of unity is not as simple as it seems at first. In particular, the formulas given in a standard programmer's reference book (Knuth, Seminumerical Algorithms, 1981) are shown to be numerically unstable, giving unacceptably large error for moderate sized sequences. We give alternative formulas, which we show to be superior both by analysis and experiment.

## Article:

## INTRODUCTION

In most efficient implementations of the fast Fourier transform (FFT), tables of the powers of the roots of unity are precomputed so that expensive trigonometric function evaluation can be avoided when computing the transform. In this correspondence, we consider the problem of precomputing these values. For a good survey of issues arising in computing the FFT, the reader may refer to the excellent paper by Duhamel and Vetterli [1]. In particular, we show that the method given in a standard reference text [2] is numerically unstable, and can produce very inaccurate values for moderately sized sequences. More importantly, we present an alternative way of calculating the roots of unity, present analysis that shows its superiority over the previous method, and finally give empirical results showing that the benefits of the new method are indeed substantial. In addition, while computation time is not a big issue in the computations that we describe, our methods are computationally simpler than the previous method, so there seems to be no reason to choose the previous method over our new method.

We consider the problem of computing the complex roots of unity $w_{n}^{k}=\mathrm{e}^{2 \pi i k / n}$ for $\mathrm{k}=0,1, \cdots, n-1$, where $n$ is a power of two. It is well known that if the set of values $W_{r}=e^{2 \pi i / 2^{r}}$ are known for $r=0,1, \cdots, \log _{2} n$, then the entire table of $w_{n}^{k}$ values can be computed by a very simple linear time algorithm (only a single complex multiplication is required per table entry). The accuracy of the $w_{n}^{k}$ values depends entirely on the accuracy of the $W_{r}$ values, so we concentrate on computing the $W_{r}$ values.

We can consider computing the real and imaginary parts of $W_{r}=c_{r}+i s_{r}$ separately, where

$$
\begin{equation*}
c_{r}=\cos \left(\frac{2 \pi}{2^{r}}\right) s_{r}=\sin \left(\frac{2 \pi}{2^{r}}\right) \tag{1}
\end{equation*}
$$

In a standard programmer's reference book [2, p. 2921, Knuth gives the following recurrence equations for computing these sequences:

$$
\begin{equation*}
\tilde{c}_{r+1}=\sqrt{\frac{1+\tilde{c}_{r}}{2}} \tilde{s}_{r+1}=\sqrt{\frac{1-\tilde{c}_{r}}{2}} . \tag{2}
\end{equation*}
$$

While the equation for $\bar{c}_{r}$ is stable, it should be obvious that since $\tilde{c}_{r}$ approaches one rather quickly, the equation for $\tilde{s}_{r}$ involves the subtraction of almost equal quantities and thus is very unstable.

In this correspondence, we propose the following set of equations:

$$
\begin{equation*}
\tilde{c}_{r+1}=\frac{1}{2} \sqrt{2\left(1+\tilde{c}_{r}\right)} \tilde{s}_{r+1}=\frac{\tilde{s}_{r}}{\sqrt{2\left(1+\tilde{c}_{r}\right)}} \tag{3}
\end{equation*}
$$

We will show by both analysis and experiment that the equations in (3) have much better error properties than the equations in (2). Furthermore, notice that in the equations in (3) a common factor has been found for both equations, meaning that only one square root needs to be taken when evaluating both equations. Therefore, not only are the new equations better in terms of error propagation, but they are also computationally simpler.

## II. ANALYSIS

In this section, we will show that the formulas in equation (3) are correct mathematical representations of the series defined in equation (1), and that the formulas in equation (3) are stable.
'The correctness of the formulas in (3) is obvious from the standard double-angle identities of trigonometry (see, for example, [31), namely

$$
\cos \alpha=\sqrt{\frac{1+\cos 2 \alpha}{2}} \sin \alpha=\frac{\sin 2 \alpha}{2 \cos \alpha}
$$

Thus, it is obvious that if the recurrences could be computed exactly, then they would give the precise answers desired. Unfortunately, since most computers use binary floating point numbers for computations, and since the numbers we are computing are irrational, exact computation is impossible.

In analyzing the stability of the recurrence equations in this correspondence, we will use $u$ to represent machine precision. We assume that all computations are performed to this precision. In other words, if $x$ and $y$ represent binary floating point numbers, then adding these numbers produces an answer $(1+\delta)(x+y)$, where $\delta$ represents the relative error introduced by rounding the result to fixed, finite precision, and we know that $|\delta| \leq u$.

As an example of the stability analysis, as well as to demonstrate why Knuth's recurrence for $s$, is unstable, we will analyze the second recurrence in (2). In particular, we consider

$$
\tilde{s}_{r+1}=\sqrt{\frac{1-\bar{c}_{r}}{2}} .
$$

Let $\delta_{c}$ represent the relative error in the approximation $\tilde{c}_{r}\left(\right.$ so $\left.\bar{c}_{r}=\left(1+\delta_{c}\right) c_{r}\right)$, let $\delta_{1}$ represent the relative error introduced in the subtraction, and let $\delta_{2}$ represent the relative error introduced by talcing the square root. We will assume that dividing by two can be done exactly, since this is just a decrement of the floating point exponent.

With these error terms, we can write the value that actually gets computed as

$$
\begin{aligned}
\tilde{s}_{r+1} & =\left(1+\delta_{2}\right) \sqrt{\frac{\left(1-c_{r}\left(1+\delta_{c}\right)\right)\left(1+\delta_{1}\right)}{2}} \\
& =\left[\frac{1-c_{r}\left(1+\delta_{c}\right)}{1-c_{r}}\right]^{1 / 2}\left(1+\delta_{1}\right)^{1 / 2}\left(1+\delta_{2}\right) \sqrt{\frac{1-c_{r}}{2}} \\
& =\left[1-\frac{\delta_{c} c_{r}}{1-c_{r}}\right]^{1 / 2}\left(1+\delta_{1}\right)^{1 / 2}\left(1+\delta_{2}\right) s_{r+1} .
\end{aligned}
$$

If we were proving stability results about this equation, we would next go on to bound the relative error of the above expression. However, since for this equation we only wish to see that the recurrence is unstable, all that is required is examining the first term in the expression above. From our definitions (see (1)), it fairly easy to see that $\frac{1}{1-c_{r}} \approx \frac{2^{2 r}}{2 \pi^{2}}$, so the error grows rapidly with $r$. Thus, Knuth's method for computing the $s_{r}$ series is unstable.

We prove that our equations are stable in proof of the following theorem.
Theorem 1: If the formulas given in (3) are computed using floating point binary with precision $u \leq \frac{1}{10}$, and if we define the error terms $\delta_{c, r}$ and $\delta_{s, r}$ by

$$
\tilde{c}_{r}=\left(1+\delta_{c, r}\right) c_{r} \quad \tilde{s}_{r}=\left(1+\delta_{s, r}\right) s_{r},
$$

then, for all $r \geq 1$,

$$
\left|\delta_{c, r}\right| \leq 5 u \quad\left|\delta_{s, r}\right| \leq(1+10 u)^{r}-1
$$

Note: At first glance, it appears that the error bound for $\delta_{s, r}$ is unacceptable, since it grows exponentially. However, since $u$ is typically very small, the geometric ratio of this sequence is actually very close to one. For example, in the most common form of single precision representation, the mantissa has 24 bits, so we can use $u$ $=2^{-23}$. Even when $r=20$ (corresponding to an WI' of over a million elements), the bound in the Theorem 1 says that $\left|\delta_{s, 20}\right|<2^{-15}$. In fact, with a more rigorous proof, it can be proved that for $u=2^{-23}$, the error is bounded by $\left|\delta_{s, 20}\right|<2^{-17}$. Experimental results (see Section III) show that in fact the error may be much smaller than shown by this upper bound.

Proof: As above, we will make explicit the rounding errors introduced from computation using finite precision numbers. Consider the computation of $\tilde{c}_{r+1}$ in (3). As before, we make the realistic assumption that multiplication and division by two can be performed exactly, so these computations add no error to the final result. Thus, the computation of $\tilde{c}_{r+1}$ is represented by

$$
\begin{aligned}
\tilde{c}_{r+1} & =\frac{1}{2}\left(1+\delta_{2}\right) \sqrt{2\left(1+\delta_{1}\right)\left(1+\left(1+\delta_{c, r}\right) c_{r}\right)} \\
& =\left(1+\delta_{1}\right)^{1 / 2}\left(1+\delta_{2}\right)\left(1+\frac{\delta_{c, r} c_{r}}{1+c_{r}}\right)^{1 / 2} c_{r+1}
\end{aligned}
$$

where $\delta_{1}$ represents the relative error caused by the addition, $\delta_{2}$ represents the relative error caused by the square root, and $\delta_{c, r}$ represents the relative error of the approximation $\tilde{c}_{r}$. Obviously, if we can find a positive value $\epsilon$ such that

$$
(1-\epsilon) \leq\left(1+\delta_{1}\right)^{1 / 2}\left(1+\delta_{2}\right)\left(1+\frac{\delta_{c, r} c_{r}}{1+c_{r}}\right)^{1 / 2} \leq(1+\epsilon)
$$

Then we have proved the bound $\left|\delta_{c, r+1}\right| \leq \epsilon$.
We will now introduce an easily verified fact that will be helpful in proving error bounds.
Fact 1: Let $\alpha_{1}$ and $\alpha_{2}$ be small constants, and define $\alpha_{\max }=\max \left\{\left|\alpha_{1}\right|,\left|\alpha_{2}\right|\right\}$. Then

$$
\left(1-\alpha_{\max }\right) \leq\left[\left(1+\alpha_{1}\right)\left(1+\alpha_{2}\right)\right]^{1 / 2} \leq\left(1+\alpha_{\max }\right) .
$$

Returning to the analysis of the relative error introduced in the computation of $\tilde{c}_{r+1}$, using Fact 1 from above, and the fact that $\frac{c_{r}}{1+c_{r}}<\frac{1}{2}$, we can clearly bound the relative error by

$$
\begin{aligned}
& (1-u)\left(1-\max \left(u, \frac{1}{2}\left|\delta_{c, r}\right|\right)\right. \\
& \leq\left(1+\delta_{1}\right)^{1 / 2}\left(1+\delta_{2}\right)\left(1+\frac{\delta_{c, r} c_{r}}{1+c_{r}}\right)^{1 / 2} \\
& \leq(1+u)\left(1+\max \left(u, \frac{1}{2}\left|\delta_{c, r}\right|\right)\right) .
\end{aligned}
$$

Since $u \leq \frac{1}{10}$, a little manipulation yields

$$
(1+u)\left(1+\max \left(u, \frac{1}{2}\left|\delta_{c, r}\right|\right) \leq 1+\frac{21}{10} u+\frac{11}{20}\left|\delta_{c, r}\right| .\right.
$$

Note that this is a somewhat looser bound than can obtained, but it will suffice for our purposes. An even tighter lower bound can be trivially obtained, giving our intermediate result that

$$
\left|\delta_{c, r+1}\right| \leq \frac{21}{10} u+\frac{11}{20}\left|\delta_{c, r}\right| .
$$

From this equation, it can easily be shown by induction that for all $r \geq 1$

$$
\left|\delta_{c, r}\right| \leq \frac{14}{3} u<5 u
$$

which completes the proof of the first error bound in the theorem statement.
To prove the error bound for the $\tilde{s}_{r}$ sequence, first notice that the denominator of the recurrence for $\tilde{s}_{r}$ in (3) will have relative error $\delta_{c, r+1}$, Since the denominator is only a factor of two different from the value $\tilde{c}_{r+1}$. In other words, we know that

$$
\begin{aligned}
\tilde{s}_{r+1} & =\frac{\tilde{s}_{r}}{\sqrt{2\left(1+\tilde{c}_{r}\right)}}=\frac{\left(1+\delta_{s, r}\right) s_{r}}{\left(1+\delta_{c, r+1}\right) \sqrt{2\left(1+c_{r}\right)}} \\
& =\frac{1+\delta_{s, r}}{1+\delta_{c, r+1}} s_{r+1} .
\end{aligned}
$$

Now, we introduce another easily verifies fact to simplify analysis.
Fact 2: if $|\delta| \leq \frac{1}{2}$, then

$$
(1-2|\delta|) \frac{1}{|x|} \leq \frac{1}{(1+\delta)|x|} \leq(1+2|\delta|) \frac{1}{|x|}
$$

TABLE I
Empirical Comparison of Stability of the Two Algorithms

|  | Knuth's <br> Method |  | Stable <br> Method |  |
| :---: | :---: | :---: | :---: | :---: |
| $r$ | $s_{r}$ | Rel. Err. | $s_{r}$ | Rel. Err. |
| 3 | $7.07107 \mathrm{e}-01$ | $1.71 \mathrm{e}-08$ | $7.07107 \mathrm{e}-01$ | $1.71 \mathrm{e}-08$ |

| 10 | $6.13517 \mathrm{e}-03$ | $1.16 \mathrm{e}-04$ | $6.13588 \mathrm{e}-03$ | $7.21 \mathrm{e}-08$ |
| 11 | $3.06880 \mathrm{e}-03$ | $2.75 \mathrm{e}-04$ | $3.06796 \mathrm{e}-03$ | $7.30 \mathrm{e}-08$ |
| 12 | $1.53440 \mathrm{e}-03$ | $2.74 \mathrm{e}-04$ | $1.53398 \mathrm{e}-03$ | $3.53 \mathrm{e}-08$ |
| 13 | $7.72040 \mathrm{e}-04$ | $6.58 \mathrm{e}-03$ | $7.66990 \mathrm{e}-04$ | $2.59 \mathrm{e}-08$ |
| 14 | $3.86020 \mathrm{e}-04$ | $6.58 \mathrm{e}-03$ | $3.83495 \mathrm{e}-04$ | $2.36 \mathrm{e}-08$ |
| 15 | $1.72633 \mathrm{e}-04$ | $9.97 \mathrm{e}-02$ | $1.91748 \mathrm{e}-04$ | $4.19 \mathrm{e}-08$ |
| 16 | $0.00000 \mathrm{e}+00$ | $1.00 \mathrm{e}+00$ | $9.58738 \mathrm{e}-05$ | $4.65 \mathrm{e}-08$ |
| 17 | $0.00000 \mathrm{e}+00$ | $1.00 \mathrm{e}+00$ | $4.79369 \mathrm{e}-05$ | $4.77 \mathrm{e}-08$ |
| 18 | $0.00000 \mathrm{e}+00$ | $1.00 \mathrm{e}+00$ | $2.39684 \mathrm{e}-05$ | $4.80 \mathrm{e}-08$ |
| 19 | $0.00000 \mathrm{e}+00$ | $1.00 \mathrm{e}+00$ | $1.19842 \mathrm{e}-05$ | $4.80 \mathrm{e}-08$ |
| 20 | $0.00000 \mathrm{e}+00$ | $1.00 \mathrm{e}+00$ | $5.99211 \mathrm{e}-06$ | $4.81 \mathrm{e}-08$ |

Using Fact 2 in conjunction with the error bound that we have already proved for $\delta_{c, r+1}$, we get

$$
(1-10 u)\left(1-\left|\delta_{s, r}\right|\right) s_{r+1} \leq \tilde{s}_{r+1} \leq(1+10 u)\left(1+\left|\delta_{s, r}\right|\right) s_{r+1} .
$$

In other words

$$
\left|\delta_{s, r+1}\right| \leq(1+10 u)\left|\delta_{s, r}\right|+10 u
$$

or (solving this recurrence)

$$
\left|\delta_{s, r+1}\right| \leq(1+10 u)^{r+1}-1
$$

which completes the proof of the second error bound.

## III. EMPIRICAL RESULTS

In this section, we report on results obtained in some simple implementations of both methods of computing roots of unity. The implementations calculated approximate $c_{r}$ and $s_{r}$ series' using single precision floating point operations. To compute the error, we compared these values with the double precision values computed by the library functions $\sin (x)$ and $\cos (x)$. The formulas for $c_{r}$ given by Knuth and in this correspondence are essentially the same, so the two implementations give identical results and have very small errors. On the other hand, the computed $s_{r}$ values show some significant differences, and the results of our experiments are shown in Table I.

As can be seen from the table, the error in computing the $s_{r}$ series via the method found in Knuth's book has significant errors around the tenth term. In fact, at the thirteenth term, the relative error of Knuth's method is approximately five orders of magnitude worse than the new method presented in this paper. These experiments show that the instability of Knuth's method is a very real problem, but one that can be overcome by using (3).

## IV. CONCLUSION

We have demonstrated that the method for computing roots of unity given in a standard programmer's reference guide [2] is unstable. The instability is apparent from the analysis, and experimental evidence shows that the instability is indeed a problem for realistically sized data sets.

More importantly, in (3) we have given alternative formulas for the computation of the roots of unity. We have shown both by analysis and experiment that the new equations are indeed stable, and provide substantially more accurate results than the previous formulas. In addition, although the complexity of the equations is not a great issue for this problem, the new formulas are computationally simpler than the previous ones. Given these results, it seems that the formulas in (3) are the only reasonable way of computing the complex roots of unity.
