Approximation of maps into spheres by regulous maps

Maciej Zielińskid

Abstract. Let X be a compact real algebraic set of dimension n. We prove that every Euclidean continuous map from X into the unit n-sphere can be approximated by a regulous map. This strengthens and generalizes previously known results.

Mathematics Subject Classification. 14P05, 14P25.

Keywords. Real algebraic variety, Regulous map, Sphere, Approximation.

1. Introduction. A recent direction of research in real algebraic geometry is to study intermediate classes of maps between continuous and regular maps. Such classes as continuous rational maps, stratified-regular maps, and regulous maps (which often coincide) have been studied in a series of papers [3,7,8,11–27]. The aim of this note is to strengthen a certain related result of [21] and [15].

We begin by fixing some terminology. A real algebraic variety is a locally ringed space isomorphic to some algebraic subset of \mathbb{R}^n , for some positive integer n, endowed with the Zariski topology and the sheaf of regular functions. It is worth recalling that this class is identical with the class of quasi-projective real varieties, for more detail and information see [4]. A morphism of real algebraic varieties is called a *regular map*. We will be also interested in the Euclidean topology of such varieties and this is the topology we will mean, unless explicitly stated otherwise, when using topological notions. By a smooth map we understand a map of class \mathcal{C}^{∞} .

Let X be a real algebraic variety. A stratification S of X is a finite collection of pairwise disjoint Zariski locally closed subvarieties whose union is equal to X. A map $f: X \to Y$ of real algebraic varieties is said to be *regulous* if it is continuous and if there exists some stratification S of X such that $f|_S$ is a regular map for every $S \in S$. We denote the set of all regulous maps between X and Y by $\mathcal{R}^0(X, Y)$. We shall treat $\mathcal{R}^0(X, Y)$ as a subspace of the space $\mathcal{C}(X,Y)$ of all continuous maps endowed with the compact-open topology. Note that regulous maps in the sense of our definition were called stratifiedregular in [21] and the follow-up papers [20,22]. This definition is different but equivalent to that of [7] where the terminology was introduced, see [21, Remark 2.3] or [24].

Each regulous map is also *continuous rational*—i.e. f is continuous and $f|_{X^0}$ is regular for some Zariski open dense subset $X^0 \subset X$. While the converse is false in general, it is true if X is nonsingular, see [11].

Let us first recall the following result contained in [15].

Theorem 1.1. Let X be a compact nonsingular real algebraic variety of dimension $p \ge 1$. Then the set $\mathcal{R}^0(X, \mathbb{S}^p)$ is dense in $\mathcal{C}(X, \mathbb{S}^p)$.

A related weaker result allowing for a singular X is contained in [21]:

Theorem 1.2. Let X be a compact real algebraic variety of dimension $p \ge 1$. Then any continuous map $X \to \mathbb{S}^p$ is homotopic to a regulous map.

Our aim is to strenghten Theorem 1.2 by showing that the nonsingularity assumption of Theorem 1.1 is unnecessary.

Theorem 1.3. Let X be a compact real algebraic variety of dimension $p \ge 1$. Then the set $\mathcal{R}^0(X, \mathbb{S}^p)$ is dense in $\mathcal{C}(X, \mathbb{S}^p)$.

It is well known that analogous results do not hold if regulous maps in Theorems 1.1, 1.2, and 1.3 are replaced with regular maps. For example, a continuous map $\mathbb{S}^1 \times \mathbb{S}^1 \to \mathbb{S}^2$ is homotopic to a regular map if and only if it is null-homotopic, cf. [5].

2. Proof of the main theorem. We shall use the concept of the algebraic cohomology classes of a real algebraic variety which we recall now. Let X be a compact nonsingular real algebraic variety. A class in $H^*(X; \mathbb{Z}/2)$ is said to be algebraic if it is Poincaré dual to a homology class in $H_*(X, \mathbb{Z}/2)$ represented by an algebraic subset. The set $H^*_{alg}(X; \mathbb{Z}/2)$ of all algebraic cohomology classes is a subring of $H^*(X; \mathbb{Z}/2)$ and if $f: X \to Y$ is a regular map, then the induced map f^* in cohomology maps $H^*_{alg}(Y; \mathbb{Z}/2)$ into $H^*_{alg}(X, \mathbb{Z}/2)$, cf. [2,4,6].

An important tool we need is [15, Lemma 2.2], which allows controlled approximation of continuous maps into projective space by regular maps. We restate it here for convenience.

Lemma 2.1. Let X be a compact nonsingular real algebraic variety, and let A be a Zariski closed subvariety of X. Let $f: X \to \mathbb{P}^n(\mathbb{R})$ be a continuous map whose restriction $f|_A: A \to \mathbb{P}^n(\mathbb{R})$ is a regular map. Assume that

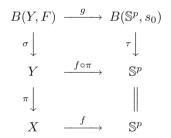

$$f^*(H^1(\mathbb{P}^n(\mathbb{R});\mathbb{Z}/2)) \subset H^1_{\mathrm{alg}}(X;\mathbb{Z}/2).$$

Then one can find a regular $g: X \to \mathbb{P}^n(\mathbb{R})$ arbitrarily close to f and satisfying $g|_A = f|_A$ (i.e. every neighborhood of f in $\mathcal{C}(X, \mathbb{P}^n(\mathbb{R}))$ contains such a map).

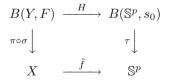

We are now ready to prove Theorem 1.3

Proof. Let f be any map in $\mathcal{C}(X, \mathbb{S}^p)$. Treating X as a closed subset of \mathbb{R}^m for some $m \in \mathbb{N}$, one can find a smooth map $f_0: U \to \mathbb{S}^p$ defined on some neighborhood U of X in \mathbb{R}^m such that $f_0|_X$ is arbitrarily close to f. Let Σ denote the singular locus of X. Then $f_0(\Sigma) \subsetneq \mathbb{S}^p$, since dim $\Sigma < p$. This allows us to approximate $f_0|_{\Sigma}$ by regular maps using the stereographic projection and Weierstrass approximation theorem. We can therefore reduce the proof (by replacing f with suitably modified f_0) to the case where f is a restriction of a smooth map defined on a neighborhood of X in \mathbb{R}^m and $f|_{\Sigma}$ is regular with $f(\Sigma) \subsetneq \mathbb{S}^p$. Then, by Sard's theorem, there exists an $s_0 \in \mathbb{S}^p \setminus f(\Sigma)$ which is a regular value of the smooth map $f|_{X \setminus \Sigma}$.

By Hironaka's resolution of singularities theorem [9,10], there exists a finite composition of blowups $\pi: Y \to X$ over Σ with Y nonsingular. The restriction $\overline{\pi}: Y \setminus \pi^{-1}(\Sigma) \to X \setminus \Sigma$ of π is then a biregular isomorphism and s_0 is a regular value of the smooth map $f \circ \overline{\pi}$. Letting $F = (f \circ \pi)^{-1}(s_0) = (f \circ \overline{\pi})^{-1}(s_0)$, consider the blowup of Y with center F, which we will denote $\sigma: B(Y, F) \to Y$, and the blowup $\tau: B(\mathbb{S}^p, s_0) \to \mathbb{S}^p$ of \mathbb{S}^p over s_0 . Since dim X = p, the set F is finite as a fiber of the smooth map $f \circ \overline{\pi}$ over its regular value s_0 , hence B(Y, F) is a real algebraic variety. Finiteness of F and the fact that $f \circ \pi$ is also a smooth map allow us to apply [1, Lemma 2.5.9] in order to construct a smooth lifting g of $f \circ \pi$ to a map between B(Y, F) and $B(\mathbb{S}^p, s_0)$ making the following diagram commute:

Our aim for now is to find a regular map $H: B(Y, F) \to B(\mathbb{S}^p, s_0)$ arbitrarily close to g in $\mathcal{C}(B(Y, F), B(\mathbb{S}^p, s_0))$ in such a way that the map $\tilde{f}: X \to \mathbb{S}^p$ making the following diagram commute will be regulous and close to f:

Let $D = \sigma^{-1}(F)$ and $E = \tau^{-1}(s_0)$. Then D and E are nonsingular algebraic hypersurfaces in the respective blowups. Let $u \in H^1(B(Y,F);\mathbb{Z}/2)$ be the cohomology class Poincaré dual to the homology class in $H_*(B(Y,F);\mathbb{Z}/2)$ represented by D and let v be the class in $H^1(B(\mathbb{S}^p, s_0);\mathbb{Z}/2)$ dual to the class in $H_*(B(\mathbb{S}^p, s_0);\mathbb{Z}/2)$ represented by E. Recall that there exists a biregular isomorphism $\varphi: B(\mathbb{S}^p, s_0) \to \mathbb{P}^p(\mathbb{R})$ such that

$$\varphi(E) = \mathbb{P}^{p-1}(\mathbb{R}) \subset \mathbb{P}^p(\mathbb{R}).$$
(1)

$$g^*(H^1(B(\mathbb{S}^p, s_0); \mathbb{Z}/2)) \subset H^1_{\mathrm{alg}}(B(Y; F); \mathbb{Z}/2).$$
 (2)

Let $i: D \to B(Y, F)$ and $j: E \to B(\mathbb{S}^p, s_0)$ be the inclusion maps and let $\bar{g}: D \to E$ be the map induced by the restriction of g to D. Then, since $g \circ i = j \circ \bar{g}$ we have $\bar{g}^*(j^*(v)) = i^*(g^*(v)) = i^*(u)$. This allows us to apply Lemma 2.1 to approximate \bar{g} by regular maps. Indeed, since by (1) $H^1(E; \mathbb{Z}/2)$ is generated by $j^*(v)$ and by definition $i^*(u)$ is in $H^1_{alg}(D; \mathbb{Z}/2)$, we have

$$\bar{g}^*(H^1(E;\mathbb{Z}/2)) \subset H^1_{\mathrm{alg}}(D;\mathbb{Z}/2).$$

Therefore, there exists a regular map $r: D \to E$ arbitrarily close to \overline{g} in $\mathcal{C}(D, E)$.

Let $L = (\pi \circ \sigma)^{-1}(\Sigma)$ and let $h: \Sigma \to B(\mathbb{S}^p, s_0)$ be the regular map given by $(\tau|_{\tau^{-1}(\mathbb{S}^p \setminus \{s_0\})})^{-1} \circ (f|_{\Sigma})$. We now extend $j \circ r$ to a smooth map $G: B(Y, F) \to B(\mathbb{S}^p, s_0)$ close to g such that $G|_L = (h \circ \pi \circ \sigma)|_L$ (this is possible since the sets E and L are disjoint). If G is close enough to g, we have $g^* = G^*$ and hence by (2) we can apply Lemma 2.1 to G with $A = D \cup L$. This gives a regular map $H: B(Y, F) \to B(\mathbb{S}^p, s_0)$ which is close to g and satisfies $H|_L = (h \circ \pi \circ \sigma)|_L$ and $H(D) \subset E$. The latter shows that the map $\overline{H}: Y \to \mathbb{S}^p$ given by

$$\bar{H}(y) = \begin{cases} s_0, & \text{for } y \in F, \\ \tau(H(\sigma^{-1}(y))), & \text{for } y \notin F, \end{cases}$$

is continuous and well-defined. Moreover $\overline{H}(y) = f \circ \pi(y)$ for $y \in \pi^{-1}(\Sigma)$. Also note that \overline{H} is close to $f \circ \pi$, since $(\tau \circ H)|_{Y \setminus F}$ is close to $\tau \circ f \circ \pi$. Therefore, the map $\widetilde{f} : X \to \mathbb{S}^p$ given by

$$\tilde{f}(x) = \begin{cases} f(x), & \text{for } x \in \Sigma, \\ \bar{H}(\pi^{-1}(x)), & \text{for } x \notin \Sigma, \end{cases}$$

is well-defined, continuous, and can be chosen arbitrarily close to f.

It remains to check that \tilde{f} is regulous. Since $\tilde{f}|_{\Sigma}$ is regular as is \tilde{f} in restriction to the finite set $f^{-1}(s_0)$, it is enough to show $\tilde{f}|_{X\setminus A}$ is regular where $A = \Sigma \cup f^{-1}(s_0)$. Since we have $\tilde{f}|_{X\setminus A} = \tau \circ H \circ (\sigma|_{Y\setminus F})^{-1} \circ (\pi|_{X\setminus \Sigma})^{-1}$ with all the maps on the right-hand side regular, the proof is finished. \Box
