Accepted 10 March 2000

The structures of diaqua(1,7-dioxa-4-thia-10-azacyclododecane)nickel dinitrate, $[\text{Ni}(\text{C}_8\text{H}_{17}\text{NO}_2\text{S})(\text{H}_2\text{O})_2](\text{NO}_3)_2$, (I), bis(nitratoo-*O,O'*)(1,4,7-trioxa-10-azacyclododecane)mercury, $[\text{Hg}(\text{NO}_3)_2(\text{C}_8\text{H}_{17}\text{NO}_3)]$, (II), and aqua(nitratoo-*O*)(1-oxa-4,7,10-triazacyclododecane)copper nitrate, $[\text{Cu}(\text{NO}_3)(\text{C}_8\text{H}_{19}\text{N}_3\text{O})(\text{H}_2\text{O})]\text{NO}_3$, (III), reveal each macrocycle binding in a tetradentate manner. The conformations of the ligands in (I) and (III) are the same and distinct from that identified for (II). These differences are in agreement with molecular-mechanics predictions of ligand conformation as a function of metal-ion size.

Comment

The coordination chemistry of 12-membered macrocycles has been dominated by the symmetrical N₄ (cyclen) and O₄ (12-crown-4) ligands. Mixed-donor macrocycles have been much less extensively studied, due in part to the greater complexity of their syntheses. There are a number of possible combinations of N-, O- and S-donor atoms in a 12-membered macrocyclic ring (substituted at the 1,4,7,10 positions), and it has

been found that judicious replacement of heteroatoms by either harder or softer donors can have a marked effect on the thermodynamic stability, and hence metal-ion selectivity, of

the macrocycle (Byriel *et al.*, 1993; Afshar *et al.*, 1999; Marcus *et al.*, 1999). In this paper, we report the crystal structures of the Ni^{II}, Hg^{II} and Cu^{II} complexes of three different mixed-donor macrocycles comprising NO₂S, NO₃ and N₃O donor sets, respectively.

The crystal structure of $[\text{NiL}^1(\text{OH}_2)_2](\text{NO}_3)_2$ ($L^1 = 1,7\text{-dioxa-4-thia-10-azacyclododecane}$) (Fig. 1) comprises separate complex cations with neither anion bound to the metal. The Flack (1983) parameter [0.00 (2)] establishes unequivocally that the space group $P6_5$ is correct and not the enantiomorphous $P6_1$ space group. The complex cation is six-coordinate, with the macrocycle adopting a non-planar *cis* conformation. The two aqua ligands are thus forced to occupy *cis* coordination sites. The aqua ligands exhibit the shortest coordinate bonds (Table 1), the ether and amine donors display slightly longer bond lengths, while the Ni—S bond is the longest, as expected. There are a number of hydrogen bonds involving both the aqua ligands and the amine-H atoms as donors (Table 2). The macrocycle adopts an asymmetric [2424] conformation (Buschmann, 1987). This conformation has also been observed in the structures of $[\text{NiL}^4(\text{OH}_2)(\text{ONO}_2)]\text{NO}_3$ and the dimer $\{[\text{CuL}^4(\text{OH})_2]\}(\text{ClO}_4)_2$, where L^4 is the N_3S analogue of L^1 (Marcus *et al.*, 1999). The Hg^{II} complex of L^1 (Byriel *et al.*, 1993) finds the ligand in the [3333] conformation, where the four donor atoms are approximately coplanar and the metal ion is displaced well above this plane, in contrast to the present structure.

The crystal structure of $[\text{Hg}L^2(\text{O}_2\text{NO})_2]$ ($L^2 = 1,4,7\text{-trioxa-10-azacyclododecane}$) (Fig. 2) comprises the tetradentate coordinated ligand in the [3333] conformation and two nitroato ligands. In contrast with the structure of $[\text{Ni}^{\text{I}}(\text{OH}_2)_2]^{2+}$, there is a large difference between the macrocyclic $\text{Hg}-\text{N}$ and $\text{Hg}-\text{O}$ bond lengths (Table 3), with the former being *ca* 0.4 Å shorter. This reflects the preference of Hg for amines compared with harder ether donors. Both nitroato ligands coordinate asymmetrically, with unequal $\text{Hg}-\text{O}$ bond lengths. Moreover, one nitroato ligand is bound more tightly [$\text{Hg1}-\text{O}4$ 2.166 (5) and $\text{Hg1}-\text{O}5$ 2.698 (6) Å] than the other [$\text{Hg1}-\text{O}8$ 2.541 (5) and $\text{Hg1}-\text{O}9$ 2.906 (6) Å]. The sole hydrogen-bond donor (the amine-H atom) forms an intermolecular hydrogen bond with the non-coordinated O atom of one nitroato ligand (Table 4). The only other report of a crystal structure of L^2 is the complex $[\text{Na}(L^2)]\text{I}$, where both ligands exhibit the [3333]

conformation (White *et al.*, 1987). More common are structural reports of N-functionalized derivatives of L^2 (so-called lariat ethers; Schultz *et al.*, 1985).

The structure of $[\text{CuL}^3(\text{OH}_2)(\text{ONO}_2)]\text{NO}_3$ ($L^3 = 1\text{-oxa-4,7,10-triazacyclododecane}$) (Fig. 3) defines a six-coordinate, distorted octahedral complex cation, comprising one weakly bound nitrate ligand, and one free nitrate anion both on general sites. The macrocycle adopts a folded [2424] conformation as seen in the $[\text{NiL}^1(\text{OH}_2)_2]^{2+}$ structure. The electronic preference of Cu^{II} for axially elongated five- and six-coordinate geometries is evident from the significantly longer axial Cu—O2 and Cu—O5 bond lengths (Table 5) compared with the equatorial bonds involving the N-donors and aqua ligand. Numerous hydrogen bonds are formed involving the aqua ligands and the amine-H atoms as donors (Table 6). This structure is closely related to $[\text{CuL}^3\text{Br}]\text{PF}_6$ (Felix *et al.*, 1994), where a bromo ligand replaces the aqua ligand in the present structure. The other structural report of an L^3 complex is that of $[\text{MnL}^3(\text{NCS})_2]$ (Zhang *et al.*, 1992).

It has been established that 12-membered macrocycles are too small to encircle a metal ion, and either *cis*-octahedral coordination or square-based pyramidal structures are found. In no case is the metal coplanar with the four donor atoms. We have reported recently a molecular-mechanics analysis of the

conformational preference of the 12-membered N_3S macrocyclic relative of L^1 for metal ions of various sizes (Marcus *et al.*, 1999). The conclusions of this analysis were that the [3333] conformation of ligands of this class will be dominant when the metal–ligand bond lengths are large ($>2.25 \text{ \AA}$), and the crystal structures observed so far are in agreement with this.

Experimental

The title complexes were crystallized from methanolic solutions containing equimolar amounts of the corresponding metal(II) nitrate and ligand L^1 (Byriel *et al.*, 1993), L^2 (Calverley & Dale, 1981) or L^3 (Thöm *et al.*, 1986).
