Abstract: The novel heteroditopic receptors 5a~c have been synthesized, which bear a thiacalix[4]arene in the 1,3-alternate conformation. Two urea moieties possessing various aryl groups with either electron-donating or -withdrawing groups at their p-positions function as anion-binding sites. At the opposite side of the cavity are two pyrene-appended triazole rings, which act as cation-binding sites. The binding property of receptor 5c was investigated by means of 1H NMR and UV-vis spectroscopy and by fluorescence titration experiments in the presence of various transition metal

cations and anions in CH2Cl2-DMSO (10:1, v/v) solution. Interestingly, it was found that receptor 5c possessing two p-nitrophenyl ureido moieties, most efficiently complexes in the urea cavity or

bistriazoles; the plausible allosteric effect of receptor 5c was also investigated.

ABSTRACT

Article history: Received Received in revised form Accepted Available online

Keywords: Thiacalix[4]arene 1,3-alternate Conformation Pyrenyl-appended triazole Urea Allosteric effect

The novel heteroditopic receptors $\mathbf{5}_{\mathbf{a} \sim \mathbf{c}}$ have been synthesized, which bear a thiacalix[4]arene in the 1,3-alternate conformation. Two urea moieties possessing various aryl groups with either electron-donating or -withdrawing groups at their p-positions function as anion-binding sites. At the opposite side of the cavity are two pyrene-appended triazole rings, which act as cationbinding sites. The binding property of receptor 5c was investigated by means of ¹H NMR and UV-vis spectroscopy and by fluorescence titration experiments in the presence of various transition metal cations and anions in CH2Cl2-DMSO (10:1, v/v) solution. Interestingly, it was found that receptor $\mathbf{5}_{c}$ possessing two p-nitrophenyl ureido moieties, most efficiently complexes in the urea cavity or bistriazoles; the plausible allosteric effect of receptor 5_c was also investigated.

1. Introduction

The investigation of macrocycles such as calix[n] arenes which are attractive building blocks for creating host systems capable of selectively recognizing cation, anion or neutral molecules has become an active area of research in supramolecular chemistry. Thiacalix[4]arenes^{2,3} which are sulfur-bridged analogs of calix[4] arenes are excellent scaffolds and have been utilized in chemosensors, supramolecular selfassemblies and the catalytic activity of enzymes. A large number of enzymes have allosteric sites to control catalytic activity by stabilizing the active conformation. Many systems based on thiacalix[4]arenes are capable of host-guest interactions and involve conformational changes caused by the allosteric binding4 of metal cations, and these relate to the maintenance of the essential material balance necessary for life. Anions also have been widely employed in biological, environmental and industrial processes.⁵ The development of anion selective sensors⁶ based on calix[n] arenes has received a considerable amount of attention in the area of supramolecular chemistry. Calix[n]arene urea derivatives are extremely prominent and are efficient for anion complexations via the N-

Chung¹¹ and co-workers reported a fluorescent chemosensor bearing a calix[4]arene in a 1,3-alternate conformation, which contains two anthracene-appended triazole rings and the crown-ether moiety. 11a This receptor exhibited a negative allosteric effect between the Pb2+ and K+ ions in common organic solvents. Moreover, they also reported that a homobinuclear ditopic fluorescent chemosensor bearing a 1,3-alternate calix[4]arene, which contained two anthraceneappended triazole rings and two phenylenaminones at the opposite sides of the calix[4]arene cavity. 11d This receptor exhibited a positive allosteric effect between two equivalents of Ag⁺ ion in common organic solvents. However, investigations

H protons due to the formation of hydrogen bonds.^{7,8} Click chemistry⁹ is one of the most useful and widely employed reactions in synthetic chemistry. In particular, the Cu(I)catalyzed azide-alkyne cycloaddition reaction is a highly versatile method which can be performed in high yield under very mild conditions. The 1,4-disubstituted-1,2,3-triazole products can act as relatively stable functional groups as covalent linkers or as ligands for metal cations, and have been utilized in the fields of drug discovery and materials science. Recently, many calix[n] arene derivatives bearing 1,4disubstituted-1,2,3-triazoles as linking groups have been developed and investigated. 10

concerning the appearance of allosteric effects in analogues based on thiacalix[4]arenes/metal cations/anions has not yet been reported. Herein, we have independently designed a heterodimeric system¹² based on a thiacalix[4]arene having two different side arms. Specifically, we have incorporated two ureas moieties which link various phenyl groups substituted with the electron–donating or –withdrawing groups at the *p*–positions and two pyrene–appended triazole rings at the opposite side of thiacalix[4]arene cavity. We built up the hypothesis that the heterodimeric system, which is controlled by the complexation of the opposite side arms with Cl⁻ and Ag⁺ ions, exhibits an effective positive allosteric effect.

2. Results and discussion

2.1. Synthesis

O-Alkylation of distal-1 was carried out with 10 equiv. of propargyl bromide in the presence of 10 equiv. of Cs₂CO₃ according to the reported procedure to afford the desired 1,3-alternate-2 in 85 % yield. 12 A Cu(I)-catalyzed 1,3-dipolar cycloaddition reaction of 1,3-alternate-2 with 4 equiv. of 1-azidomethylpyrene via Click chemistry was carried out according to the reported procedure, and afforded the 1,2,3-triazole thiacalix[4]arene 1,3-alternate-3 in 48 % yield. The hydrazinolysis of 1,3-alternate-3 was carried out with a large excess of hydrazine hydrate to afford the desired 1,3alternate-4 in 86 % yield. The condensation of 1,3-alternate-4 with 4 equiv. of the appropriate isocyanate in THF furnished the receptors $\mathbf{5}_{\mathbf{a}\sim\mathbf{c}}$ in good yield (Scheme 1). In general, the ¹H NMR spectra of receptors $\mathbf{5}_{\mathbf{a}\sim\mathbf{c}}$ in CDCl₃-DMSO (10:1, v/v) exhibited the characteristics of a 1,3-alternate canformation, viz two singlets (18H each) for the tert-butyl protons, one singlet (4H) for OCH2CO protons, one singlet (4H) for OCH_2 -triazole protons, two singlets (4H each) for aromatic protons, two singlets (2H each) for four urea NH protons and one singlet (2H) for triazole–H protons. Moreover, a concentration dependence of the ¹H NMR chemical shifts of the ureido protons in receptor 5_c was not observed (Figure S13). This result suggests that receptor 5c has a strong intramolecular hydrogen

bond between the two ureas moieties.

2.2. Binding studies

Upon addition of Cl⁻ ion (0–20 μ M) to a solution of receptor $\mathbf{5}_{c}$ (1.0 µM), Figure S19 shows that both the monomer and excimer emissions of the pyrene units gradually decrease. A Job's plot binding between receptor 5_c and Cl⁻ ion reveals a 1:1 stoichiometry (Figure S20), while the association constant (K_a value) for the complexation with Cl⁻ ion by receptor 5_c was determined to be 42500 ± 2975 M⁻¹ as determined by the fluorescence titration experiment in CH₂Cl₂-DMSO (10:1, v/v) (Figure S21 and Table 1). Moreover, K_a values between the receptors $\mathbf{5}_{a \sim b}$ and Cl⁻ ion were determined by analyzing fluorescence titration experiments, respectively (Figures S15-S18 and Table 1). These results suggest that the association constants depend on the electrondonating/withdrawing groups located at the p-position. In the presence of the electron-withdrawing group NO_2 (receptor $\mathbf{5}_c$), the K_a value was greater than that for the unsubstituted receptor (receptor $\mathbf{5}_{a}$). In contrast, in the case of receptor $\mathbf{5}_{b}$, with the electron-donating Me group, there was a general decrease in the K_a value for the complexation with Cl ion in comparison to the case in the unsubstituted receptor 5_a. Therefore, the introduction of electronwithdrawing groups at the p-position appears to increase the acidity of the urea protons, and hence enhance the anion-binding ability through hydrogen-bonding interactions. The K_a value of receptor $\mathbf{5}_c$ with the electron-withdrawing NO₂ group at the p-position was the best out of all the K_a values between receptors $\mathbf{5}_{\mathbf{a}\sim\mathbf{c}}$ and Cl⁻ ion. From

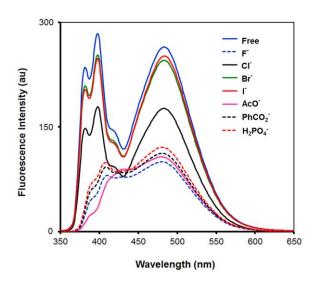

Fig. 1 Fluorescence spectral changes of receptor $\mathbf{5}_c$ (1.0 μM) upon addition of various tested anions (1.0 μM) in CH₂Cl₂–DMSO (10:1, v/v). $\lambda_{ex}=343$ nm.

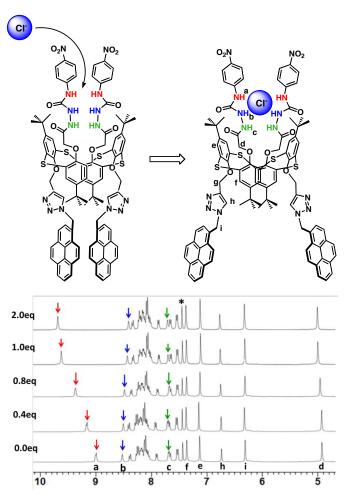

Fig. 2 Binding mode of receptor $\mathbf{5}_c$ upon addition of Cl^- ion at 298 K as a tetrabutylammonium (TBA) salt and partial ¹H NMR spectra of $\mathbf{5}_c$ (4.0 mM) in CDCl₃–DMSO–CH₃CN (10:1:1, v/v) upon addition of Ag^+ ion at 298 K.

the above, we can say that the receptor $\mathbf{5}_{c}$, with the electron—withdrawing NO₂ group at the p-position, has the most effective recognition ability toward selected anions of the systems screened herein. Given this, complexation studies of receptor $\mathbf{5}_{c}$ toward targeting various transition metal cations and anions were carried out using ^{1}H NMR and UV-vis spectroscopy and by fluorescence titration experiments.

The UV-vis absorption spectra of receptor $\mathbf{5}_c$ (1.0 μ M) were recorded in the presence of various anions (20 equiv.) in CH₂Cl₂-DMSO (10:1, v/v) as shown in Figure S14. The receptor $\mathbf{5}_{c}$ (1.0 μM)exhibits an absorption band at 347 nm in the UV-vis absorption spectra in the absence of anions. Interestingly, significant changes moving to a longer wavelength in absorption spectra were observed in the presence of F⁻, AcO⁻, PhCOO⁻ or H₂PO₄⁻ with a color change from colourless to dark yellow by the naked eye, respectively. These results suggest that the quinoid structure was formed by the deprotonation of the urea NH groups in the p-nitrophenyl ureido moiety. Figure 1 reveals the fluorescence intensity changes of the monomer (393 nm) and excimer (486 nm) emissions for receptor 5_c in the presence of various anions. Receptor $\mathbf{5}_{\mathbf{c}}$ exhibited a decrease in intensity of both the monomer and excimer emissions with various anions. Upon addition of Cl⁻ ion to a solution of receptor 5_c, the decrease of intensity of the monomer emission is presumably caused by a photo-induced electron transfer (PET) mechanism which

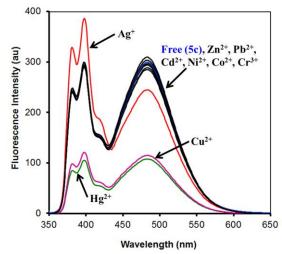

Fig. 3 Fluorescence spectral changes of receptor $\mathbf{5}_{c}$ (1.0 μ M) to upon addition of various tested metal cations (20 μ M) in CH₂Cl₂–DMSO (10:1, v/v). λ_{ex} = 343 nm.

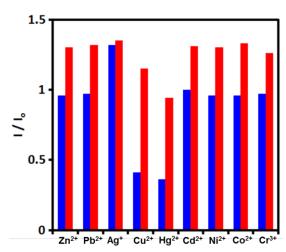

Fig. 4 Fluorescence response of receptor $\mathbf{5_c}$ (1.0 μ M) in CH₂Cl₂–DMSO (10:1, v/v) to various tested metal cations (20 μ M) (blue bar) and to the mixture of tested metal ions (20 μ M) with Ag $^+$ ion (20 μ M) (red bar) at 298 K. I $_0$ is the fluorescence intensity at 393 nm for free receptor $\mathbf{5_c}$, and I is the fluorescence intensity after adding metal ions with an excitation at 343 nm.

operates from the oxygen of the urea moiety which complexes with the Cl⁻ ion via hydrogen bonding to the pyrene moieties. By contrast, upon addition of F⁻, AcO⁻, PhCOO⁻ or H₂PO₄⁻ ions to a solution of receptor $\mathbf{5_c}$, the decreasing intensity of the monomer emission is caused by deprotonation of the urea NH groups which induces a PET mechanism from the anionic nitrogen to the pyrene moieties. On the other hand, upon addition of F⁻, Cl⁻, AcO⁻, PhCOO⁻ or H₂PO₄⁻ ions to a solution of receptor $\mathbf{5_c}$, the decreasing intensity of the excimer emission is caused by conformational unstacking of two pyrene ureas, which breaks down an intramolecular π - π interaction because of complex formation. As shown in Figure 2, the signals for the NH_a protons (red) progressively shifted downfield by 0.64 ppm (δ = 8.98 to 9.62 ppm) until one equiv. of Cl⁻ ion was added. On the other hand, the signals for the NH_b protons (blue) progressively shifted upfield by 0.09 ppm (δ = 8.50 to 8.41 ppm) until one equiv. of Cl⁻

ion was added. These results strongly suggested Cl⁻ ion recognition by receptor 5_c via a hydrogen-bonding interaction between Cl⁻ ion and N-H protons as shown in Figure 2 and Figure S32. The fluorescence intensity changes of receptor $\mathbf{5}_{\mathbf{c}}$ were recorded in CH₂Cl₂-DMSO (10:1, v/v) in the presence of a 20-fold excess of various metal cations and their fluorescence spectra thus obtained were compared with that recorded in the absence of metal cations under similar experimental conditions. It was observed that both the monomer and excimer emissions of receptor 5_c were strongly quenched by Cu²⁺ and Hg²⁺ ions in Figure 3. The fluorescence titration behaviour was evaluated in the case of receptor 5_c with Cu²⁺ and Hg²⁺ ions (Figures S22-S25). From these observations, the association constants for complexation were calculated to be: 5_c·Cu²⁺ = $330000 \pm 23100 \text{ M}^{-1}$, $\mathbf{5_c} \cdot \text{Hg}^{2+} = 420000 \pm 29400 \text{ M}^{-1}$, respectively. In contrast, upon addition of Ag⁺ ion into a solution of receptor 5_c, the fluorescence monomer emission was enhanced, while the excimer emission decreased. As shown in Figue 4, competitive experiments were carried out in the presence of Ag⁺ ion (20 μM) mixed with other metal cations (20 μ M). These results suggested that the receptor $\mathbf{5}_{c}$ exhibits selective fluorescent behaviour towards the Ag⁺ ion. Upon addition of Ag⁺ ion (0-20 μM) to a solution of receptor $\mathbf{5}_{c}$ (1.0 μ M), Figure S26 shows the excimer emission of the pyrene units (486 nm) dicreases and the monomer emission of the pyrene units (393 nm) increases. This is because the complexation of Ag⁺ ion by receptor 5_c induces the conformational unstacking of two pyrene ureas resulting in quenching of an intramolecular π - π interaction. Meanwhile, a discernible isoemissive point was observed at 445 nm. A Job's plot binding between receptor 5_c and Ag⁺ ion reveals a 1:1 stoichiometry (Figure S27), while the association constant (K_a) for the complexation with Ag^+ ion by receptor $\mathbf{5}_c$ was determined to be $61975 \pm 4336 \text{ M}^{-1}$ as determined by the

fluorescence titration experiment in CH₂Cl₂-DMSO (10:1, v/v) (Figure S28). The fluorescent titration profile for receptor $\mathbf{5}_{c}$ with Ag⁺ ion demonstrated that the detection limit of Ag⁺ ion was 1.92 × 10^{-7} M (Figure S29). As a result, receptor $\mathbf{5}_{c}$ can be regarded as being highly sensitive to the Ag+ ion, especially given the large fluorescence dynamic range and the low detection limit of 1.92×10^{-3} ⁷ M. The quantum yield of the free receptor $\mathbf{5}_{c}$ is $\Phi = 0.11$, for both the monomer and excimer emission (393 and 486 nm). The quantum yield of the receptor $\mathbf{5}_{c} \cdot \mathbf{Ag}^{+}$ complex is $\Phi = 0.06$ as a result of increased monomer emission. To elucidate the complexation behaviour of receptors 5_c with Ag⁺ ion in detail, ¹H NMR spectroscopic titration experiments in CDCl3-DMSO-CH3CN (10:1:1, v/v) were carried out. Upon addition of 1.0 equiv. of Ag⁺ ion to the solution of receptors $\mathbf{5}_{c}$, a large downfield shift of 1.08 ppm (δ = 6.72 to 7.80 ppm) for the proton H_h on the triazole ring was observed, together with a downfield shift of 0.20 ppm (δ = 4.32 to 4.52 ppm) for the proton H_g on the OCH₂-triazole unit and a downfield shift of 0.17 ppm ($\delta = 7.33$ to 7.50 ppm) for the proton H_f on the aromatic protons of thiacalix[4] arene cavity; the chemical shifts of the NH protons did not change. This result suggested that the Ag⁺ ion can be selectively bound by the nitrogen atoms on the triazole rings and is included in the π -basic benzene cavity at the lower rim. The two distal benzene rings were flattened and the residual two benzene rings were standing upright for the binding of the Ag⁺ ion as shown in Figure 5. On the basis of the above, we investigated the appearance of an allosteric effect by the complexation of the opposite side arms with Cl⁻ and Ag⁺ ions by ¹H NMR spectroscopic and fluorescence titration experiments. The result of the fluorescence titration experiments of receptor $\mathbf{5}_{c}$. Cl⁻ with Ag+ ion are shown in Figure S33. When increasing concentrations of Ag⁺ ion were added to a solution of receptor 5_c· Cl⁻, the fluorescence intensity of the monomer (393 nm) and excimer (486 nm) emissions of pyrene gradually increased because of an allosteric effect via an ion-pair electrostatic interaction and a conformational change of the flexible thiacalix[4]arene cavity. Further addition of more than 1.0 equiv. of Ag⁺ ion led to a significant increase in the monomer emission of the pyrene units, while the accompanying excimer emission reached a plateau upon adding about 20 equiv of Ag⁺ ion. The association constant of receptor $\mathbf{5}_{c}$ · Cl⁻ with Ag⁺ ion was determined to be 325000 ± 22750 M⁻¹ by the fluorescence titration experiment in CH₂Cl₂–DMSO (10:1, v/v) (Figure S34). The results indicated that receptor $\mathbf{5_c}$ · Cl⁻ was complexed with the Ag⁺ ion at two pyrene-appended triazole rings by a positive allosteric effect because the complexation with Cl⁻ ion in the urea cavity caused an ion-pair electrostatic interaction and a conformational change of the flexible thiacalix[4]arene cavity. The fluorescent titration profile for receptor 5_c· Cl⁻ with Ag⁺ ion demonstrated that the detection limit of Ag⁺ ion was 1.02×10^{-8} M (Figure S35). As a result, in comparison to the case in the free receptor $\mathbf{5_c}$ to the Ag⁺ ion (1.92 × 10⁻⁷ M), receptor $\mathbf{5_c}$ · Cl⁻ can be regarded as being more highly sensitive to the Ag+ ion. To investigate further the possible appearance of an effective allosteric effect between receptor $\mathbf{5_c}$. Cl⁻ and the Ag⁺ ion, ¹H NMR titration experiments in CDCl₃-DMSO-CD₃CN (10:1:1, v/v) were conducted. When only Cl⁻ ion was added, it was observed that the signal for the NH_a protons shifted downfield, while the signal for NH_b protons shifted upfield. However, the signals of the protons on the two pyrene-appended triazole ring moieties did not shift (Figures 6a and 6b). This result suggests a Cl⁻ ion recognition of receptor 5_c by a hydrogen-bonding interaction between the Cl⁻ion and N-H protons.

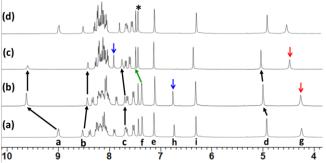

Fig. 6 Proposed positive allosteric behaviour of receptor $\mathbf{5}_c$ with Cl¯ and Ag⁺ ions. Partial 1H NMR spectra of $\mathbf{5}_c$ /guest (H/G = 1:1); a) free $\mathbf{5}_c$; b) $\mathbf{5}_c \supset Bu_4NCl$; c) AgSO₃CF₃ \subset [$\mathbf{5}_c \supset Cl$ \subset]; d) $\mathbf{5}_c \supset AgSO_3CF_3$. Solvent: CDCl₃ \subset DMSO–CD₃CN (10:1:1, v/v). 300 MHz at 298 K. *Denoted the solvent peak.

Furthermore, when Ag^+ ion was added to a solution of $[\mathbf{5}_c \supset Bu_4NCI]$ (Figure 6c), this addition induced a large downfield shift of 1.22 ppm $(\delta = 6.72 \text{ to } 7.94 \text{ ppm})$ for the proton H_h on the triazole ring, a downfield shift of 0.18 ppm $(\delta = 4.32 \text{ to } 4.50 \text{ ppm})$ for the proton H_g on the OCH_2 –triazole unit and a downfield shift of 0.15 ppm $(\delta = 7.33 \text{ to } 7.48 \text{ ppm})$ for the proton H_f of the aromatic protons of thiacalix[4]arene cavity. The chemical shifts for all NH protons did not change. These results suggested the formation of a heterogeneous dinuclear complex $Ag^+ \subset [\mathbf{5}_c \supset CI^-]$ (Figure 6c), and we propose a positive allosteric effect for receptor $\mathbf{5}_c$ toward the Ag^+ ion in the presence of the CI^- ion as shown in Figure 6.

In summary, the novel heteroditopic receptors $\mathbf{5}_{\mathbf{a-c}}$ bearing a thiacalix[4]arene in a 1,3-alternate conformation have been synthesized. These receptors possess two ureas moieties linking various aryl groups bearing electron-donating or -withdrawing substituents at their *p*-positions which act as anion-binding sites and two pyrene-appended triazole rings which act as cation-binding sites at the opposite side of thiacalix[4]arene cavity. Furthermore, we have shown that two ureas moieties can bind various anions having a wide range of geometries based on UV-vis absorption, fluorescence and ^1H NMR titration experiments. We have also shown that the triazole groups can bind Ag^+ , Hg^{2^+} and Cu^{2^+} ions based on both fluorescence spectroscopy and ^1H NMR titration experiments. Upon addition of Hg^{2^+} and Cu^{2^+} ions to a solution of receptor $\mathbf{5}_c$ in $\text{CH}_2\text{Cl}_2\text{-DMSO}$ (10:1, v/v), the

fluorescence spectrum was strongly quenched because of a reverse PET from the pyrene moieties to the triazole groups. By contrast, upon addition of Ag^+ ion to a solution of receptor $\mathbf{5_c}$ in CH_2Cl_2 –DMSO (10:1, v/v), the fluorescence monomer emission was enhanced, while the excimer emission declined because of the complexation of the Ag^+ ions with the triazole groups. Interestingly, the fluorescence of receptor $\mathbf{5_c}$ was quenched by Cl^- ion, but could be revived by the addition of Ag^+ ion to the receptor $\mathbf{5_c} \cdot Cl^-$ complex. The appearance of a positive allosteric effect in receptor $\mathbf{5_c}$ was investigated based on fluorescence and 1H NMR titration experiments. Interestingly, the formation of heterogeneous dinuclear complex Ag^+ – $[\mathbf{5_c}$ – $Cl^-]$ of receptor $\mathbf{5_c}$ with Cl^- and Ag^+ ions by a positive allosteric effect could be observed.

4. Experimental section

4.1 General

Unless otherwise stated, all reagents used were purchased from commercial sources and were used without further purification. Compounds $\mathbf{1}$, $\mathbf{1}^{13}$ $\mathbf{2}^{12e}$ and $\mathbf{3}^{12e}$ were prepared following the reported procedures. All solvents used were dried and distilled by the usual procedures prior to use. All melting points (Yanagimoto MP-S1) are uncorrected. ¹H NMR and ¹³C NMR spectra were recorded on a Nippon Denshi JEOL FT-300 NMR spectrometer and Varian-400MR-vnmrs400 with SiMe4 as an internal reference: J-values are given in Hz. IR spectra were measured for samples as KBr pellets on a Nippon Denshi JIR-AQ2OM spectrophotometer. Mass spectra were obtained with a Nippon Denshi JMS-HX110A Ultrahigh Performance mass spectrometer at 75 eV by using a direct-inlet system. UV-vis spectra were recorded using a Shimadzu UV-3150UV-vis-NIR spectrophotometer. Fluorescence spectroscopic studies of compounds in solution were performed in a semimicro fluorescence cell (Hellma®, 104F-QS, 10 × 4 mm, 1400 µL) with a Varian Cary Eclipse spectrophotometer. Fluorescence quantum yields were recorded in solution (Hamamatsu Photonics K. K. Quantaurus-QY A10094) using the integrated sphere absolute PL quantum yield measurement method. Elemental analyses were performed by a Yanaco MT-5. The elemental analysis, MS, and emission spectra were measured.

4.2. Materials

4.2.1. Synthesis of compound 4. Compound 3 (300 mg, 0.202 mmol) was put into a round-bottom flask and ethanol (50 mL), THF (50 mL) and hydrazine hydrate (6 mL, large excess) were added and the system was refluxed for 24 h. After cooling, the solvents and excess hydrazine were removed under reduced pressure to give the crude product as a white solid. The residue was triturated sequentially with water and methanol and the product collected by filtration. The residue was adsorbed in silica gel and purified by column chromatography using ethyl acetate as eluent and washed with hexane to give receptor 4a (253 mg, 86 %) as a white solid. M.p. 157–161 °C. IR: υ_{max} (KBr)/cm⁻¹: 3422, 3322, 2869, 1677, 1623, 1590, 1432, 1381, 1362, 1266, 1239, 1087, 1045, 970, 817 and 708. ¹H NMR (400 MHz, CDCl₃): $\delta = 0.95$ (18H, s, $tBu \times 2$), 0.99 (18H, s, $tBu \times 2$), 3.49 (4H, br, $NH_2 \times 2$), 4.29 (4H, s, OCH_2 -triazole \times 2), 5.06 (4H, s, $OCH_2CO \times 2$), 6.29 (4H, s, CH_2 -pyrene \times 2), 6.69 (2H, s, Triazole– $H \times 2$), 7.07 (4H, s, Ar– $H \times 2$), 7.26 (4H, s, $Ar-H \times 2$), 7.36 (2H, s, $NH \times 2$) and 7.86–8.33. 4.2.2. Synthesis of receptor 5_a. To compound 4 (100 mg, 0.0687 mmol) in THF (10 mL) was added phenyl isocyanate (45 mg, 0.275 mmol) and the mixture was stirred at room temperature for 24 h under argon. The resulting precipitate was collected by filtration, washed with methanol to give receptor 5_a as a pale yellow solid. Recrystallization from chloroform-hexane (3:1) gave receptor 5_a (154 mg, 83 %) as a pale yellow solid. M.p. 202–203 °C. IR: υ_{max} (KBr)/cm⁻¹: 3301, 2961, 2867, 1680, 1604, 1544, 1510, 1451, 1430, 1312, 1264, 1220, 1085, 1044, 842, 815, 708 and 506. ¹H NMR (400 MHz, CDCl₃-DMSO, 10:1): $\delta = 0.97$ (18H, s, $tBu \times 2$), 1.04 (18H, s, $tBu \times 2$), 4.22 (4H, s, OCH₂-triazole \times 2), 4.94 (4H, s, OCH₂CO \times 2), 6.29 (4H, s, CH₂-pyrene \times 2), 6.72 (2H, s, Triazole- $H \times 2$), 6.90-7.47 (10H, m, Phenyl- $H \times 10$), 7.12 (4H, s, Ar- $H \times 2$), 7.30 (4H, s, Ar- $H \times 2$) 2), 7.54 (2H, s, NH \times 2) and 7.81–8.39. (22H, m, Pyrene–H \times 18 and NH \times 4) ppm. ¹³C NMR (100 MHz, CDCl₃-DMSO, 10:1): $\delta = 30.6$ (CH₃), 30.8 (CH₃), 34.1 (C(CH₃)₃), 51.9 (CH₂), 62.8 (OCH₂), 69.1 (OCH₂), 118.6 (ArC), 118.7 (ArC), 122.1 (ArC), 122.3 (ArC), 122.4 (ArC), 123.2 (ArC), 124.3 (ArC), 125.6 (ArC), 125.8 (ArC), 126.1 (ArC), 126.3 (ArC), 127.1 (ArC), 127.3 (ArC), 127.7 (ArC), 128.0 (ArC), 128.6 (ArC), 128.8 (ArC), 128.9 (ArC), 130.4 (ArC), 130.7 (ArC), 131.0 (ArC), 131.9 (ArC), 138.9 (ArC), 139.6 (ArC), 143.2 (ArC), 146.9 (ArC), 148.1 (ArC), 144.4 (ArC), 153.4 (ArC), 154.9 (CO), 155.3 (ArC) and 167.4 (CO) ppm. 4.2.3. Synthesis of receptor 5_b. To compound 4 (100 mg, 0.0687 mmol) in THF (10 mL) was added *p*-tolyl isocyanate (37 mg, 0.275 mmol) and the mixture was stirred at room temperature for 24 h under argon. The resulting precipitate was collected by filtration, washed with hexane to give receptor 5_b as a pale yellow solid. Recrystallization from chloroform-hexane (3:2) gave receptor 5_b (88 mg, 75 %) as a pale yellow solid. M.p. 205–206 °C. IR: υ_{max} (KBr)/cm⁻¹: 3303, 2961, 2869, 1681, 1604, 1543, 1515, 1451, 1432, 1314, 1266, 1229, 1087, 1045, 847, 817, 708 and 507. ¹H NMR (400 MHz, CDCl₃-DMSO, 10:1): $\delta = 0.97$ (18H, s, $tBu \times 2$), 1.02 (18H, s, $tBu \times 2$), 2.27 (6H, s, $CH_3 \times 2$), 4.26 (4H, s, OCH_2 -triazole × 2), 4.95 (4H, s, $OCH_2CO \times 2$), 6.32 (4H, s, CH_2 -pyrene × 2), 6.74 (2H, s, Triazole-H × 2), 6.98 $(4H, d, J = 7.7 Hz, Phenyl-H \times 4), 7.14 (4H, s, Ar-H \times 2),$ 7.17 (4H, d, J = 7.7 Hz, Phenyl– $H \times 4$), 7.31 (4H, s, Ar– $H \times 4$) 2), 7.54 (2H, s, NH \times 2) and 7.86–8.36. (22H, m, Pyrene–H \times 18 and NH \times 4) ppm. ¹³C NMR (100 MHz, CDCl₃– DMSO, 10:1): $\delta = 21.7$ (CH₃), 31.6 (CH₃), 31.8 (CH₃), 34.9

(C(CH₃)₃), 52.3 (CH₂), 64.0 (OCH₂), 70.0 (OCH₂), 119.8 (ArC), 119.9 (ArC), 123.1 (ArC), 124.0 (ArC), 124.1 (ArC), 125.1 (ArC), 125.3 (ArC), 126.1 (ArC), 126.6 (ArC), 126.9 (ArC), 127.5 (ArC), 127.7 (ArC), 128.1 (ArC), 128.4 (ArC), 129.0 (ArC), 129.4 (ArC), 129.7 (ArC), 130.0 (ArC), 131.2 (ArC), 131.6 (ArC), 131.7 (ArC), 131.8 (ArC), 132.2 (ArC), 137.8 (ArC), 143.8 (ArC), 148.0 (ArC), 148.6 (ArC), 155.6 (ArC), 155.9 (ArC), 156.4 (ArC), 157.0 (CO) and 168.0 (CO) ppm. FABMS: m/z: 1721.5 (M $^{+}$). $C_{100}H_{96}N_{12}O_8S_4$ (1722.17): calcd C 69.74, H 5.64, N 9.76. Found: C 69.58, H 5.54, N 9.67.

4.2.4. Synthesis of receptor 5_c. To compound 4 (100 mg, 0.0687 mmol) in THF (10 mL) was added p-nitrophenyl isocyanate (45 mg, 0.275 mmol) and the mixture was stirred at room temperature for 24 h under argon. The resulting precipitate was collected by filtration, washed with methanol to give receptor 5_c as a yellow solid. Recrystallization from chloroform-acetonitrile (3:1) gave receptor 5_c (154 mg, 83 %) as white solid. M.p. 204–207 °C. IR: v_{max} (KBr)/cm⁻¹: 3366, 3338, 2961, 1733, 1597, 1554, 1508, 1433, 1330, 1302, 1248, 1201, 1178, 1113, 1087, 848 and 752. H NMR (400 MHz, CDCl₃–DMSO, 10:1): $\delta = 0.95$ (18H, s, $tBu \times 2$), 1.04 (18H, s, $tBu \times 2$), 4.32 (4H, s, OCH_2 -triazole × 2), 4.95 (4H, s, $OCH_2CO \times 2$), 6.32 (4H, s, CH_2 -pyrene $\times 2$), 6.72 $(2H, s, Triazole-H \times 2), 7.12 (4H, s, Ar-H \times 2), 7.33 (4H, s,$ $Ar-H \times 2$), 7.49 (4H, d, J = 8.8 Hz, Phenyl $-H \times 4$), 7.63 $(4H, d, J = 8.8 \text{ Hz}, \text{ Phenyl-}H \times 4), 7.66 (2H, s, NH \times 2),$ 7.87–8.33. (18H, m, Pyrene– $H \times 18$), 8.50 (2H, s, N $H \times 2$) and 8.98 (2H, s, NH \times 2) ppm. ¹³C NMR (100 MHz, CDCl₃– DMSO, 10:1): $\delta = 30.6$ (CH₃), 30.8 (CH₃), 34.0 (C(CH₃)₃), 51.9 (CH₂), 62.7 (OCH₂), 68.9 (OCH₂), 117.5 (ArC), 117.7 (ArC), 122.2 (ArC), 123.1 (ArC), 124.3 (ArC), 124.7 (ArC), 124.9 (ArC), 125.0 (ArC), 125.6 (ArC), 125.7 (ArC), 125.8 (ArC), 126.2 (ArC), 127.1 (ArC), 127.2 (ArC), 127.5 (ArC), 128.0 (ArC), 128.4 (ArC), 128.6 (ArC), 128.9 (ArC), 130.4 (ArC), 130.7 (ArC), 131.0 (ArC), 131.7 (ArC), 142.0 (ArC), 143.1 (ArC), 145.2 (ArC), 145.3 (ArC), 147.2 (ArC), 148.0 (ArC), 154.4 (ArC), 154.9 (CO) and 167.4 (CO) ppm. FABMS: m/z: 1783.6 (M⁺). $C_{98}H_{90}N_{14}O_{12}S_4$ (1784.1): calcd C 65.97, H 5.08, N 10.99. Found: C 65.78, H 5.51, N 10.82.

4.3. Determination of the Association Constants

The association constants were determined by using 1 H NMR titration experiments in a constant concentration of host receptor $(4.0 \times 10^{-3} \text{ M})$ by varying the guest concentration $(0-8.0 \times 10^{-3} \text{ M})$. The 1 H NMR chemical shift of the urea protons (NH) signal was used as a probe. The association constant $(K_{\rm a})$ for the complexes of receptor $\mathbf{5}_{\rm a-c}$ were calculated by nonlinear curve-fitting analysis of the observed chemical shifts of the NH protons according to the literature procedure. 14

4.4. ¹H NMR Titration Experiments

A solution of Bu₄NX (X = F, Cl, Br, I, AcO, PhCOO, H_2PO_4) in CD₃CN (4.0 × 10⁻³ M) was added to a CDCl₃–DMSO (10:1, v/v) solution of receptor $\mathbf{5}_{\mathbf{a}\sim\mathbf{c}}$ in the absence or presence of AgSO₃CF₃ in an NMR tube. ¹H NMR spectra were recorded after addition of the reactants and the

temperature of the NMR probe was kept constant at 27 °C. The ¹H NMR data of the most-representative complexes are given below:

receptor $\mathbf{5}_{a} \supset Ag^{+}$: ¹H NMR (300 MHz, CDCl₃–DMSO–CD₃CN, 10:1:1, v/v): $\delta = 4.52$ (4H, br, C H_2 –triazole × 2), 4.94 (4H, s, OC H_2 CO × 2), 6.29 (4H, s, C H_2 –pyrene × 2), 7.13 (4H, s, Ar–H × 2), 7.34 (4H, s, Ar–H × 2), 7.54 (2H, br, N H_c × 2), 7.68 (2H, s, Triazole–H × 2) and 7.79–8.38. (18H, m, Pyrene-H × 18) ppm.

receptor $\mathbf{5}_b \supset Ag^+$: ¹H NMR (300 MHz, CDCl₃–DMSO–CD₃CN, 10:1:1, v/v): $\delta = 4.56$ (4H, br, CH_2 –triazole × 2), 5.00 (4H, s, OC H_2 CO × 2), 6.32 (4H, s, C H_2 –pyrene × 2), 7.07 (4H, d, J = 8.8 Hz, Phenyl–H × 4), 7.12 (4H, s, Ar–H × 2), 7.30 (4H, d, J = 8.8 Hz, Phenyl–H × 4), 7.48 (4H, s, Ar–H × 2), 7.90 (2H, br, N H_c × 2), 7.95 (2H, s, Triazole–H × 2) and 8.00–8.41. (18H, m, Pyrene-H × 18) ppm.

receptor $\mathbf{5}_{c} \supset \mathrm{Ag}^{+}$: ¹H NMR (300 MHz, CDCl₃–DMSO–CD₃CN, 10:1:1, v/v): $\delta = 4.52$ (4H, br, CH_2 –triazole × 2), 4.95 (4H, s, $OCH_2CO \times 2$), 6.32 (4H, s, CH_2 –pyrene × 2), 7.12 (4H, s, Ar– $H \times 2$), 7.50 (4H, s, Ar– $H \times 2$), 7.63 (4H, d, J = 8.8 Hz, Phenyl– $H \times 4$), 7.69 (4H, d, J = 8.8 Hz, Phenyl– $H \times 4$), 7.70 (2H, br, $NH_c \times 2$), 7.80 (2H, s, Triazole– $H \times 2$), 8.02–8.30. (18H, m, pyrene- $H \times 18$), 8.45 (2H, br, $NH_b \times 2$) and 8.98 (2H, br, $NH_a \times 2$) ppm.

receptor $\mathbf{5}_{c}$ \supset Cl⁻: ¹H NMR (300 MHz, CDCl₃ \rightarrow DMSOCD₃CN, 10:1:1, v/v): $\delta = 4.32$ (4H, br, CH_2 -triazole \times 2), 5.00 (4H, s, $OCH_2CO \times 2$), 6.32 (4H, s, CH_2 -pyrene \times 2), 6.72 (2H, s, triazole– $H \times 2$), 7.12 (4H, s, Ar– $H \times 2$), 7.33 (4H, s, Ar– $H \times 2$), 7.49 (4H, d, J = 8.8 Hz, Phenyl– $H \times 4$), 7.63 (4H, d, J = 8.8 Hz, Phenyl– $H \times 4$), 7.70 (2H, br, $NH_c \times 2$), 7.87–8.33. (18H, m, Pyrene- $H \times 18$), 8.41 (2H, br, $NH_b \times 2$) and 9.62 (2H, br, $NH_a \times 2$) ppm.

Ag⁺ ⊂ [receptor $\mathbf{5}_{c}$ ⊃Cl¯]: ¹H NMR (300 MHz, CDCl₃− DMSO–CD₃CN, 10:1:1, v/v): $\delta = 4.50$ (4H, br, CH_2 –triazole × 2), 5.00 (4H, s, OC H_2 CO × 2), 6.32 (4H, s, C H_2 –pyrene × 2), 7.12 (4H, s, Ar–H × 2), 7.48 (4H, s, Ar–H × 2), 7.63 (4H, d, J = 8.8 Hz, Phenyl–H × 4), 7.69 (4H, d, J = 8.8 Hz, Phenyl–H × 4), 7.86 (2H, br, N H_c × 2), 7.94 (2H, s, Triazole–H × 2), 8.02–8.30. (18H, m, Pyrene-H × 18), 8.44 (2H, br, N H_b × 2) and 9.60 (2H, br, N H_a × 2) ppm.

Acknowledgments

This work was performed under the Cooperative Research Program of "Network Joint Research Center for Materials and Devices (Institute for Materials Chemistry and Engineering, Kyushu University)". We would like to thank the OTEC at Saga University and the International Cooperation Projects of Guizhou Province (No. 20137005) for financial support. The EPSRC is thanked for a travel grant (to CR).

Supplementary data

ARTICLE INFO

ABSTRACT

Article history: Received Received in revised form Accepted Available online

Keywords: Thiacalix[4]arene 1,3-alternate Conformation Pyrenyl-appended triazole Urea Allosteric effect

The novel heteroditopic receptors $\mathbf{5}_{\mathbf{a} \sim \mathbf{c}}$ have been synthesized, which bear a thiacalix[4]arene in the 1,3-alternate conformation. Two urea moieties possessing various aryl groups with either electron-donating or -withdrawing groups at their p-positions function as anion-binding sites. At the opposite side of the cavity are two pyrene-appended triazole rings, which act as cationbinding sites. The binding property of receptor 5c was investigated by means of ¹H NMR and UV-vis spectroscopy and by fluorescence titration experiments in the presence of various transition metal cations and anions in CH2Cl2-DMSO (10:1, v/v) solution. Interestingly, it was found that receptor $\mathbf{5}_{c}$ possessing two p-nitrophenyl ureido moieties, most efficiently complexes in the urea cavity or bistriazoles; the plausible allosteric effect of receptor 5_c was also investigated.

1. Introduction

The investigation of macrocycles such as calix[n] arenes which are attractive building blocks for creating host systems capable of selectively recognizing cation, anion or neutral molecules has become an active area of research in supramolecular chemistry. Thiacalix[4]arenes^{2,3} which are sulfur-bridged analogs of calix[4] arenes are excellent scaffolds and have been utilized in chemosensors, supramolecular selfassemblies and the catalytic activity of enzymes. A large number of enzymes have allosteric sites to control catalytic activity by stabilizing the active conformation. Many systems based on thiacalix[4]arenes are capable of host-guest interactions and involve conformational changes caused by the allosteric binding4 of metal cations, and these relate to the maintenance of the essential material balance necessary for life. Anions also have been widely employed in biological, environmental and industrial processes.⁵ The development of anion selective sensors⁶ based on calix[n] arenes has received a considerable amount of attention in the area of supramolecular chemistry. Calix[n]arene urea derivatives are extremely prominent and are efficient for anion complexations via the N-

Chung¹¹ and co-workers reported a fluorescent chemosensor bearing a calix[4]arene in a 1,3-alternate conformation, which contains two anthracene-appended triazole rings and the crown-ether moiety. 11a This receptor exhibited a negative allosteric effect between the Pb2+ and K+ ions in common organic solvents. Moreover, they also reported that a homobinuclear ditopic fluorescent chemosensor bearing a 1,3-alternate calix[4]arene, which contained two anthraceneappended triazole rings and two phenylenaminones at the opposite sides of the calix[4] arene cavity. 11d This receptor exhibited a positive allosteric effect between two equivalents of Ag⁺ ion in common organic solvents. However, investigations

H protons due to the formation of hydrogen bonds.^{7,8} Click chemistry⁹ is one of the most useful and widely employed reactions in synthetic chemistry. In particular, the Cu(I)catalyzed azide-alkyne cycloaddition reaction is a highly versatile method which can be performed in high yield under very mild conditions. The 1,4-disubstituted-1,2,3-triazole products can act as relatively stable functional groups as covalent linkers or as ligands for metal cations, and have been utilized in the fields of drug discovery and materials science. Recently, many calix[n] arene derivatives bearing 1,4disubstituted-1,2,3-triazoles as linking groups have been developed and investigated. 10

concerning the appearance of allosteric effects in analogues based on thiacalix[4]arenes/metal cations/anions has not yet been reported. Herein, we have independently designed a heterodimeric system¹² based on a thiacalix[4]arene having two different side arms. Specifically, we have incorporated two ureas moieties which link various phenyl groups substituted with the electron–donating or –withdrawing groups at the *p*–positions and two pyrene–appended triazole rings at the opposite side of thiacalix[4]arene cavity. We built up the hypothesis that the heterodimeric system, which is controlled by the complexation of the opposite side arms with Cl⁻ and Ag⁺ ions, exhibits an effective positive allosteric effect.

2. Results and discussion

2.1. Synthesis

O-Alkylation of distal-1 was carried out with 10 equiv. of propargyl bromide in the presence of 10 equiv. of Cs₂CO₃ according to the reported procedure to afford the desired 1,3-alternate-2 in 85 % yield. 12 A Cu(I)-catalyzed 1,3-dipolar cycloaddition reaction of 1,3-alternate-2 with 4 equiv. of 1-azidomethylpyrene via Click chemistry was carried out according to the reported procedure, and afforded the 1,2,3-triazole thiacalix[4]arene 1,3-alternate-3 in 48 % yield. The hydrazinolysis of 1,3-alternate-3 was carried out with a large excess of hydrazine hydrate to afford the desired 1,3alternate-4 in 86 % yield. The condensation of 1,3-alternate-4 with 4 equiv. of the appropriate isocyanate in THF furnished the receptors $\mathbf{5}_{\mathbf{a}\sim\mathbf{c}}$ in good yield (Scheme 1). In general, the ¹H NMR spectra of receptors $\mathbf{5}_{\mathbf{a}\sim\mathbf{c}}$ in CDCl₃-DMSO (10:1, v/v) exhibited the characteristics of a 1,3-alternate canformation, viz two singlets (18H each) for the tert-butyl protons, one singlet (4H) for OCH2CO protons, one singlet (4H) for OCH_2 -triazole protons, two singlets (4H each) for aromatic protons, two singlets (2H each) for four urea NH protons and one singlet (2H) for triazole–H protons. Moreover, a concentration dependence of the ¹H NMR chemical shifts of the ureido protons in receptor 5_c was not observed (Figure S13). This result suggests that receptor 5c has a strong intramolecular hydrogen

bond between the two ureas moieties

.2. Binding studies

Upon addition of Cl⁻ ion (0–20 μ M) to a solution of receptor $\mathbf{5}_{c}$ (1.0 µM), Figure S19 shows that both the monomer and excimer emissions of the pyrene units gradually decrease. A Job's plot binding between receptor $\overline{\bf 5}_c$ and $\overline{\bf Cl}^-$ ion reveals a 1:1 stoichiometry (Figure S20), while the association constant (K_a value) for the complexation with Cl⁻ ion by receptor 5_c was determined to be 42500 ± 2975 M⁻¹ as determined by the fluorescence titration experiment in CH₂Cl₂-DMSO (10:1, v/v) (Figure S21 and Table 1). Moreover, K_a values between the receptors $\mathbf{5}_{\mathbf{a} \sim \mathbf{b}}$ and Cl^- ion were determined by analyzing fluorescence titration experiments, respectively (Figures S15-S18 and Table 1). These results suggest that the association constants depend on the electrondonating/withdrawing groups located at the p-position. In the presence of the electron-withdrawing group NO_2 (receptor $\mathbf{5}_c$), the $K_{\rm a}$ value was greater than that for the unsubstituted receptor (receptor $\mathbf{5}_{a}$). In contrast, in the case of receptor $\mathbf{5}_{b}$, with the electron-donating Me group, there was a general decrease in the K_a value for the complexation with Cl ion in comparison to the case in the unsubstituted receptor 5_a. Therefore, the introduction of electronwithdrawing groups at the p-position appears to increase the acidity of the urea protons, and hence enhance the anion-binding ability through hydrogen-bonding interactions. The K_a value of receptor $\mathbf{5}_c$ with the electron-withdrawing NO₂ group at the p-position was the best out of all the K_a values between receptors $\mathbf{5}_{\mathbf{a}\sim\mathbf{c}}$ and Cl⁻ ion. From

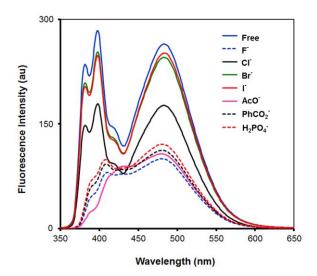

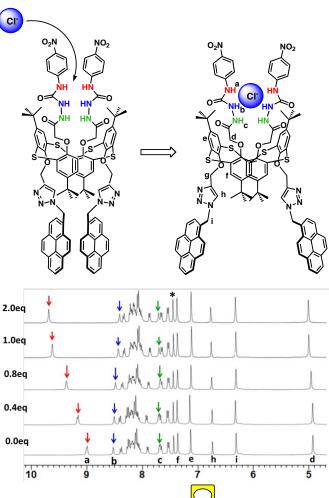

Fig. 1 Fluorescence spectral changes of receptor $\mathbf{5}_{c}$ (1.0 μ M) upon addition of various tested anions (1.0 μ M) in CH₂Cl₂–DMSO (10:1, v/v). $\lambda_{ex} = 343$ nm.

Fig. 2 Binding mode of receptor 5_c upon addition of Cl⁻ ion at 298 K as a tetrabutylammonium (TBA) salt and partial ¹H NMR spectra of 5_c (4.0 mM) in CDCl₃-DMSO-CH₃CN (10:1:1, v/v) upon addition of Ag⁺ ion at 298 K.

the above, we can say that the receptor 5_c , with the electronwithdrawing NO₂ group at the p-position, has the most effective recognition ability toward selected anions of the systems screened herein. Given this, complexation studies of receptor 5c toward targeting various transition metal cations and anions were carried out using ¹H NMR and UV-vis spectroscopy and by fluorescence titration experiments.

The UV-vis absorption spectra of receptor $\mathbf{5}_c$ (1.0 μ M) were recorded in the presence of various anions (20 equiv.) in CH₂Cl₂-DMSO (10:1, v/v) as shown in Figure S14. The receptor $\mathbf{5}_{c}$ (1.0 μM)exhibits an absorption band at 347 nm in the UV-vis absorption spectra in the absence of anions. Interestingly, significant changes moving to a longer wavelength in absorption spectra were observed in the presence of F⁻, AcO⁻, PhCOO⁻ or H₂PO₄⁻ with a color change from colourless to dark yellow by the naked eye, respectively. These results suggest that the quinoid structure was formed by the deprotonation of the urea NH groups in the p-nitrophenyl ureido moiety. Figure 1 reveals the fluorescence intensity changes of the monomer (393 nm) and excimer (486 nm) emissions for receptor 5_c in the presence of various anions. Receptor $\mathbf{5}_{\mathbf{c}}$ exhibited a decrease in intensity of both the monomer and excimer emissions with various anions. Upon addition of Cl⁻ ion to a solution of receptor 5_c, the decrease of intensity of the monomer emission is presumably caused by a photo-induced electron transfer (PET) mechanism which

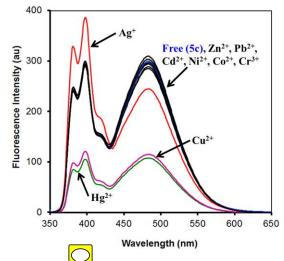

Fig. 3 Fluorescence spectral changes of receptor $\mathbf{5}_{c}$ (1.0 μ M) to upon addition of various tested metal cations (20 μ M) in CH₂Cl₂–DMSO (10:1, v/v). λ_{ex} = 343 nm.

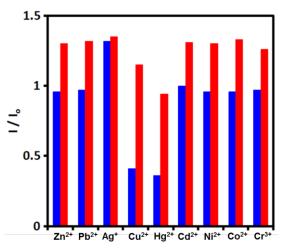

Fig. 4 Fluorescence response of receptor 5_c (1.0 μM) in CH₂Cl₂–DMSO (10:1, v/v) to various tested metal cations (20 $\mu M)$ (blue bar) and to the mixture of tested metal ions (20 μ M) with Ag⁺ ion (20 μ M) (red bar) at 298 K. I_o is the fluorescence intensity at 393 nm for free receptor 5c, and I is the fluorescence intensity after adding metal ions with an excitation at 343 nm.

operates from the oxygen of the urea moiety which complexes with the Cl⁻ ion via hydrogen bonding to the pyrene moieties. By contrast, upon addition of F-, AcO-, PhCOO- or H₂PO₄-ions to a solution of receptor 5_c, the decreasing intensity of the monomer emission is caused by deprotonation of the urea NH groups which induces a PET mechanism from the anionic nitrogen to the pyrene moieties. On the other hand, upon addition of F-, Cl-, AcO-, PhCOO- or H2PO4-ions to a solution of receptor 5c, the decreasing intensity of the excimer emission is caused by conformational unstacking of two pyrene ureas, which breaks down an intramolecular π - π interaction because of complex formation. As shown in Figure 2, the signals for the NH_a protons (red) progressively shifted downfield by 0.64 ppm ($\delta = 8.98$ to 9.62 ppm) until one equiv. of Cl⁻ ion was added. On the other hand, the signals for the NH_b protons (blue) progressively shifted upfield by 0.09 ppm ($\delta = 8.50$ to 8.41 ppm) until one equiv. of Cl

ion was added. These results strongly suggested Cl⁻ ion recognition by receptor 5_c via a hydrogen-bonding interaction between Cl⁻ ion and N-H protons as shown in Figure 2 and Figure S32. The fluorescence intensity changes of receptor $\mathbf{5}_{\mathbf{c}}$ were recorded in CH₂Cl₂-DMSO (10:1, v/v) in the presence of a 20-fold excess of various metal cations and their fluorescence spectra thus obtained were compared with that recorded in the absence of metal cations under similar experimental conditions. It was observed that both the monomer and excimer emissions of receptor 5_c were strongly quenched by Cu²⁺ and Hg²⁺ ions in Figure 3. The fluorescence titration behaviour was evaluated in the case of receptor 5_c with Cu²⁺ and Hg²⁺ ions (Figures S22-S25). From these observations, the association constants for complexation were calculated to be: 5_c·Cu²⁺ = $330000 \pm 23100 \text{ M}^{-1}$, $\mathbf{5_c \cdot Hg}^{2+} = 420000 \pm 29400 \text{ M}^{-1}$, respectively. In contrast, upon addition of Ag⁺ ion into a solution of receptor 5_c, the fluorescence monomer emission was enhanced, while the excimer emission decreased. As shown in Figue 4, competitive experiments were carried out in the presence of Ag⁺ ion (20 μM) mixed with other metal cations (20 μ M). These results suggested that the receptor $\mathbf{5}_{\mathbf{c}}$ exhibits selective fluorescent behaviour towards the Ag⁺ ion. Upon addition of Ag⁺ ion (0-20 μM) to a solution of receptor $\mathbf{5}_{c}$ (1.0 μ M), Figure S26 shows the excimer emission of the pyrene units (486 nm) dicreases and the monomer emission of the pyrene units (393 nm) increases. This is because the complexation of Ag⁺ ion by receptor 5_c induces the conformational unstacking of two pyrene ureas resulting in quenching of an intramolecular π - π interaction. Meanwhile, a discernible isoemissive point was observed at 445 nm. A Job's plot binding between receptor 5_c and Ag⁺ ion reveals a 1:1 stoichiometry (Figure S27), while the association constant (K_a) for the complexation with Ag^+ ion by receptor $\mathbf{5}_c$ was determined to be $61975 \pm 4336 \text{ M}^{-1}$ as determined by the

fluorescence titration experiment in CH₂Cl₂-DMSO (10:1, v/v) (Figure S28). The fluorescent titration profile for receptor $\mathbf{5}_{c}$ with Ag⁺ ion demonstrated that the detection limit of Ag⁺ ion was 1.92 × 10^{-7} M (Figure S29). As a result, receptor $\mathbf{5}_{c}$ can be regarded as being highly sensitive to the Ag+ ion, especially given the large fluorescence dynamic range and the low detection limit of 1.92×10^{-3} ⁷ M. The quantum yield of the free receptor $\mathbf{5}_{c}$ is $\Phi = 0.11$, for both the monomer and excimer emission (393 and 486 nm). The quantum yield of the receptor $\mathbf{5}_{c} \cdot \mathbf{Ag}^{+}$ complex is $\Phi = 0.06$ as a result of increased monomer emission. To elucidate the complexation behaviour of receptors 5_c with Ag⁺ ion in detail, ¹H NMR spectroscopic titration experiments in CDCl3-DMSO-CH3CN (10:1:1, v/v) were carried out. Upon addition of 1.0 equiv. of Ag⁺ ion to the solution of receptors $\mathbf{5}_{c}$, a large downfield shift of 1.08 ppm (δ = 6.72 to 7.80 ppm) for the proton H_h on the triazole ring was observed, together with a downfield shift of 0.20 ppm (δ = 4.32 to 4.52 ppm) for the proton H_g on the OCH₂-triazole unit and a downfield shift of 0.17 ppm ($\delta = 7.33$ to 7.50 ppm) for the proton H_f on the aromatic protons of thiacalix[4] arene cavity; the chemical shifts of the NH protons did not change. This result suggested that the Ag⁺ ion can be selectively bound by the nitrogen atoms on the triazole rings and is included in the π -basic benzene cavity at the lower rim. The two distal benzene rings were flattened and the residual two benzene rings were standing upright for the binding of the Ag⁺ ion as shown in Figure 5. On the basis of the above, we investigated the appearance of an allosteric effect by the complexation of the opposite side arms with Cl⁻ and Ag⁺ ions by ¹H NMR spectroscopic and fluorescence titration experiments. The result of the fluorescence titration experiments of receptor $\mathbf{5}_{c}$. Cl⁻ with Ag+ ion are shown in Figure S33. When increasing concentrations of Ag⁺ ion were added to a solution of receptor 5_c· Cl⁻, the fluorescence intensity of the monomer (393 nm) and excimer (486 nm) emissions of pyrene gradually increased because of an allosteric effect via an ion-pair electrostatic interaction and a conformational change of the flexible thiacalix[4]arene cavity. Further addition of more than 1.0 equiv. of Ag⁺ ion led to a significant increase in the monomer emission of the pyrene units, while the accompanying excimer emission reached a plateau upon adding about 20 equiv of Ag⁺ ion. The association constant of receptor $\mathbf{5}_{c}$. Cl⁻ with Ag⁺ ion was determined to be 325000 ± 22750 M⁻¹ by the fluorescence titration experiment in CH₂Cl₂–DMSO (10:1, v/v) (Figure S34). The results indicated that receptor $\mathbf{5_c}$ · Cl⁻ was complexed with the Ag+ ion at two pyrene-appended triazole rings by a positive allosteric effect because the complexation with Cl⁻ ion in the urea cavity caused an ion-pair electrostatic interaction and a conformational change of the flexible thiacalix[4] arene cavity. The fluorescent titration profile for receptor $\mathbf{5}_{c}$ · Cl⁻ with Ag⁺ ion demonstrated that the detection limit of Ag⁺ ion was 1.02×10^{-8} M (Figure S35). As a result, in comparison to the case in the free receptor $\mathbf{5}_c$ to the Ag⁺ ion $(1.92 \times 10^{-7} \text{ M})$, receptor $\mathbf{5}_c \cdot \text{Cl}^-$ can be regarded as being more highly sensitive to the Ag+ ion. To investigate further the possible appearance of an effective allosteric effect between receptor $\mathbf{5_c}$. Cl⁻ and the Ag⁺ ion, ¹H NMR titration experiments in CDCl₃-DMSO-CD₃CN (10:1:1, v/v) were conducted. When only Cl⁻ ion was added, it was observed that the signal for the NH_a protons shifted downfield, while the signal for NH_b protons shifted upfield. However, the signals of the protons on the two pyrene-appended triazole ring moieties did not shift (Figures 6a and 6b). This result suggests a Cl⁻ ion recognition of receptor 5_c by a hydrogen-bonding interaction between the Cl⁻ion and N-H protons.

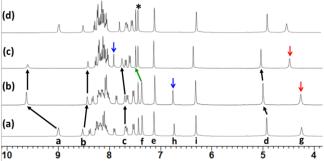

Fig. 6 Proposed positive allosteric behaviour of receptor $\mathbf{5}_c$ with Cl⁻ and Ag⁺ ions. Partial ¹H NMR spectra of $\mathbf{5}_c$ /guest (H/G = 1:1); a) free $\mathbf{5}_c$; b) $\mathbf{5}_c \supset \mathrm{Bu}_4 \mathrm{NCl}$; c) AgSO₃CF₃ \subset [$\mathbf{5}_c \supset \mathrm{Cl}$]; d) $\mathbf{5}_c \supset \mathrm{AgSO}_3 \mathrm{CF}_3$. Solvent: CDCl₃DMSO-CD₃CN (10:1:1, v/v). 300 MHz at 298 K. *Denoted the solvent peak.

Furthermore, when Ag^+ ion was added to a solution of $[\mathbf{5}_c \supset Bu_4NCI]$ (Figure 6c), this addition induced a large downfield shift of 1.22 ppm $(\delta = 6.72 \text{ to } 7.94 \text{ ppm})$ for the proton H_h on the triazole ring, a downfield shift of 0.18 ppm $(\delta = 4.32 \text{ to } 4.50 \text{ ppm})$ for the proton H_g on the OCH_2 –triazole unit and a downfield shift of 0.15 ppm $(\delta = 7.33 \text{ to } 7.48 \text{ ppm})$ for the proton H_f of the aromatic protons of thiacalix[4]arene cavity. The chemical shifts for all NH protons did not change. These results suggested the formation of a heterogeneous dinuclear complex $Ag^+ \subset [\mathbf{5}_c \supset CI^-]$ (Figure 6c), and we propose a positive allosteric effect for receptor $\mathbf{5}_c$ toward the Ag^+ ion in the presence of the CI^- ion as shown in Figure 6.

In summary, the novel heteroditopic receptors $\mathbf{5}_{\mathbf{a-c}}$ bearing a thiacalix[4]arene in a 1,3-alternate conformation have been synthesized. These receptors possess two ureas moieties linking various aryl groups bearing electron-donating or -withdrawing substituents at their *p*-positions which act as anion-binding sites and two pyrene-appended triazole rings which act as cation-binding sites at the opposite side of thiacalix[4]arene cavity. Furthermore, we have shown that two ureas moieties can bind various anions having a wide range of geometries based on UV-vis absorption, fluorescence and ^1H NMR titration experiments. We have also shown that the triazole groups can bind Ag^+ , Hg^{2^+} and Cu^{2^+} ions based on both fluorescence spectroscopy and ^1H NMR titration experiments. Upon addition of Hg^{2^+} and Cu^{2^+} ions to a solution of receptor $\mathbf{5}_c$ in $\text{CH}_2\text{Cl}_2\text{-DMSO}$ (10:1, v/v), the

fluorescence spectrum was strongly quenched because of a reverse PET from the pyrene moieties to the triazole groups. By contrast, upon addition of Ag^+ ion to a solution of receptor $\mathbf{5_c}$ in CH_2Cl_2 –DMSO (10:1, v/v), the fluorescence monomer emission was enhanced, while the excimer emission declined because of the complexation of the Ag^+ ions with the triazole groups. Interestingly, the fluorescence of receptor $\mathbf{5_c}$ was quenched by Cl^- ion, but could be revived by the addition of Ag^+ ion to the receptor $\mathbf{5_c} \cdot Cl^-$ complex. The appearance of a positive allosteric effect in receptor $\mathbf{5_c}$ was investigated based on fluorescence and 1H NMR titration experiments. Interestingly, the formation of heterogeneous dinuclear complex Ag^+ – $[\mathbf{5_c}$ – $Cl^-]$ of receptor $\mathbf{5_c}$ with Cl^- and Ag^+ ions by a positive allosteric effect could be observed.

4. Experimental section

4.1 General

Unless otherwise stated, all reagents used were purchased from commercial sources and were used without further purification. Compounds ${\bf 1},^{13}$ ${\bf 2}^{12e}$ and ${\bf 3}^{12e}$ were prepared following the reported procedures. All solvents used were dried and distilled by the usual procedures prior to use. All melting points (Yanagimoto MP-S1) are uncorrected. ¹H NMR and ¹³C NMR spectra were recorded on a Nippon Denshi JEOL FT-300 NMR spectrometer and Varian-400MR-vnmrs400 with SiMe4 as an internal reference: J-values are given in Hz. IR spectra were measured for samples as KBr pellets on a Nippon Denshi JIR-AQ2OM spectrophotometer. Mass spectra were obtained with a Nippon Denshi JMS-HX110A Ultrahigh Performance mass pectrometer at 75 eV by using a direct-inlet system. UV-vis spectra were recorded using a Shimadzu UV-3150UV-vis-NIR spectrophotometer. Fluorescence spectroscopic studies of compounds in solution were performed in a semimicro fluorescence cell (Hellma®, 104F-QS, 10 × 4 mm, 1400 µL) with a Varian Cary Eclipse spectrophotometer. Fluorescence quantum yields were recorded in solution (Hamamatsu Photonics K. K. Quantaurus-QY A10094) using the integrated sphere absolute PL quantum yield measurement method. Elemental analyses were performed by a Yanaco MT-5. The elemental analysis, MS, and emission spectra were measured.

4.2. Materials

4.2.1. Synthesis of compound 4. Compound 3 (300 mg, 0.202 mmol) was put into a round-bottom flask and ethanol (50 mL), THF (50 mL) and hydrazine hydrate (6 mL, large excess) were added and the system was refluxed for 24 h. After cooling, the solvents and excess hydrazine were removed under reduced pressure to give the crude product as a white solid. The residue was triturated sequentially with water and methanol and the product collected by filtration. The residue was adsorbed in silica gel and purified by column chromatography using ethyl acetate as eluent and washed with hexane to give receptor 4_a (253 mg, 86 %) as a white solid. M.p. 157–161 °C. IR: υ_{max} (KBr)/cm⁻¹: 3422, 3322, 2869, 1677, 1623, 1590, 1432, 1381, 1362, 1266, 1239, 1087, 1045, 970, 817 and 708. ¹H NMR (400 MHz, CDCl₃): $\delta = 0.95$ (18H, s, tBu × 2), 0.99 (18H, s, tBu × 2), 3.49 (4H, br, $NH_2 \times 2$), 4.29 (4H, s, OCH_2 -triazole \times 2), 5.06 (4H, s, $OCH_2CO \times 2$), 6.29 (4H, s, CH_2 -pyrene \times 2), 6.69 (2H, s, Triazole– $H \times 2$), 7.07 (4H, s, Ar– $H \times 2$), 7.26 (4H, s, $Ar-H \times 2$), 7.36 (2H, s, $NH \times 2$) and 7.86–8.33. 4.2.2. Synthesis of receptor 5_a. To compound 4 (100 mg, 0.0687 mmol) in THF (10 mL) was added phenyl isocyanate (45 mg, 0.275 mmol) and the mixture was stirred at room temperature for 24 h under argon. The resulting precipitate was collected by filtration, washed with methanol to give receptor 5_a as a pale yellow solid. Recrystallization from chloroform-hexane (3:1) gave receptor 5_a (154 mg, 83 %) as a pale yellow solid. M.p. 202–203 °C. IR: υ_{max} (KBr)/cm⁻¹: 3301, 2961, 2867, 1680, 1604, 1544, 1510, 1451, 1430, 1312, 1264, 1220, 1085, 1044, 842, 815, 708 and 506. ¹H NMR (400 MHz, CDCl₃-DMSO, 10:1): $\delta = 0.97$ (18H, s, $tBu \times 2$), 1.04 (18H, s, $tBu \times 2$), 4.22 (4H, s, OCH₂-triazole \times 2), 4.94 (4H, s, OCH₂CO \times 2), 6.29 (4H, s, CH₂-pyrene \times 2), 6.72 (2H, s, Triazole- $H \times 2$), 6.90-7.47 (10H, m, Phenyl- $H \times 10$), 7.12 (4H, s, Ar- $H \times 2$), 7.30 (4H, s, Ar- $H \times 2$) 2), 7.54 (2H, s, NH \times 2) and 7.81–8.39. (22H, m, Pyrene–H \times 18 and NH \times 4) ppm. ¹³C NMR (100 MHz, CDCl₃-DMSO, 10:1): $\delta = 30.6$ (CH₃), 30.8 (CH₃), 34.1 (C(CH₃)₃), 51.9 (CH₂), 62.8 (OCH₂), 69.1 (OCH₂), 118.6 (ArC), 118.7 (ArC), 122.1 (ArC), 122.3 (ArC), 122.4 (ArC), 123.2 (ArC), 124.3 (ArC), 125.6 (ArC), 125.8 (ArC), 126.1 (ArC), 126.3 (ArC), 127.1 (ArC), 127.3 (ArC), 127.7 (ArC), 128.0 (ArC), 128.6 (ArC), 128.8 (ArC), 128.9 (ArC), 130.4 (ArC), 130.7 (ArC), 131.0 (ArC), 131.9 (ArC), 138.9 (ArC), 139.6 (ArC), 143.2 (ArC), 146.9 (ArC), 148.1 (ArC), 144.4 (ArC), 153.4 (ArC), 154.9 (CO), 155.3 (ArC) and 167.4 (CO) ppm. FABMS: m/z: 1693.5 (M⁺). $C_{98}H_{92}N_{12}O_8S_4$ (1694.11): calcd C 69.48, H 5.47, N 9.92. Found: C 69.56, H 5.35, N 9.79.

4.2.3. Synthesis of receptor 5_b. To compound 4 (100 mg, 0.0687 mmol) in THF (10 mL) was added p-tolyl isocyanate (37 mg, 0.275 mmol) and the mixture was stirred at room temperature for 24 h under argon. The resulting precipitate was collected by filtration, washed with hexane to give receptor 5_b as a pale yellow solid. Recrystallization from chloroform-hexane (3:2) gave receptor 5_b (88 mg, 75 %) as a pale yellow solid. M.p. 205–206 °C. IR: υ_{max} (KBr)/cm⁻¹: 3303, 2961, 2869, 1681, 1604, 1543, 1515, 1451, 1432, 1314, 1266, 1229, 1087, 1045, 847, 817, 708 and 507. ¹H NMR (400 MHz, CDCl₃-DMSO, 10:1): $\delta = 0.97$ (18H, s, $tBu \times 2$), 1.02 (18H, s, $tBu \times 2$), 2.27 (6H, s, $CH_3 \times 2$), 4.26 (4H, s, OCH_2 -triazole × 2), 4.95 (4H, s, $OCH_2CO \times 2$), 6.32 (4H, s, CH_2 -pyrene × 2), 6.74 (2H, s, Triazole-H × 2), 6.98 $(4H, d, J = 7.7 Hz, Phenyl-H \times 4), 7.14 (4H, s, Ar-H \times 2),$ 7.17 (4H, d, J = 7.7 Hz, Phenyl– $H \times 4$), 7.31 (4H, s, Ar– $H \times 4$) 2), 7.54 (2H, s, NH \times 2) and 7.86–8.36. (22H, m, Pyrene–H \times 18 and NH \times 4) ppm. ¹³C NMR (100 MHz, CDCl₃– DMSO, 10:1): $\delta = 21.7$ (CH₃), 31.6 (CH₃), 31.8 (CH₃), 34.9

(C(CH₃)₃), 52.3 (CH₂), 64.0 (OCH₂), 70.0 (OCH₂), 119.8 (ArC), 119.9 (ArC), 123.1 (ArC), 124.0 (ArC), 124.1 (ArC), 125.1 (ArC), 125.3 (ArC), 126.1 (ArC), 126.6 (ArC), 126.9 (ArC), 127.5 (ArC), 127.7 (ArC), 128.1 (ArC), 128.4 (ArC), 129.0 (ArC), 129.4 (ArC), 129.7 (ArC), 130.0 (ArC), 131.2 (ArC), 131.6 (ArC), 131.7 (ArC), 131.8 (ArC), 132.2 (ArC), 137.8 (ArC), 143.8 (ArC), 148.0 (ArC), 148.6 (ArC), 155.6 (ArC), 155.9 (ArC), 156.4 (ArC), 157.0 (CO) and 168.0 (CO) ppm. FABMS: m/z: 1721.5 (M $^{+}$). $C_{100}H_{96}N_{12}O_8S_4$ (1722.17): calcd C 69.74, H 5.64, N 9.76. Found: C 69.58, H 5.54, N 9.67.

4.2.4. Synthesis of receptor 5_c. To compound 4 (100 mg, 0.0687 mmol) in THF (10 mL) was added p-nitrophenyl isocyanate (45 mg, 0.275 mmol) and the mixture was stirred at room temperature for 24 h under argon. The resulting precipitate was collected by filtration, washed with methanol to give receptor 5_c as a yellow solid. Recrystallization from chloroform-acetonitrile (3:1) gave receptor 5_c (154 mg, 83 %) as white solid. M.p. 204–207 °C. IR: v_{max} (KBr)/cm⁻¹: 3366, 3338, 2961, 1733, 1597, 1554, 1508, 1433, 1330, 1302, 1248, 1201, 1178, 1113, 1087, 848 and 752. H NMR (400 MHz, CDCl₃–DMSO, 10:1): $\delta = 0.95$ (18H, s, $tBu \times 2$), 1.04 (18H, s, $tBu \times 2$), 4.32 (4H, s, OCH_2 -triazole × 2), 4.95 (4H, s, $OCH_2CO \times 2$), 6.32 (4H, s, CH_2 -pyrene $\times 2$), 6.72 $(2H, s, Triazole-H \times 2), 7.12 (4H, s, Ar-H \times 2), 7.33 (4H, s,$ $Ar-H \times 2$), 7.49 (4H, d, J = 8.8 Hz, Phenyl $-H \times 4$), 7.63 $(4H, d, J = 8.8 \text{ Hz}, \text{ Phenyl-}H \times 4), 7.66 (2H, s, NH \times 2),$ 7.87–8.33. (18H, m, Pyrene– $H \times 18$), 8.50 (2H, s, N $H \times 2$) and 8.98 (2H, s, NH \times 2) ppm. ¹³C NMR (100 MHz, CDCl₃– DMSO, 10:1): $\delta = 30.6$ (CH₃), 30.8 (CH₃), 34.0 (C(CH₃)₃), 51.9 (CH₂), 62.7 (OCH₂), 68.9 (OCH₂), 117.5 (ArC), 117.7 (ArC), 122.2 (ArC), 123.1 (ArC), 124.3 (ArC), 124.7 (ArC), 124.9 (ArC), 125.0 (ArC), 125.6 (ArC), 125.7 (ArC), 125.8 (ArC), 126.2 (ArC), 127.1 (ArC), 127.2 (ArC), 127.5 (ArC), 128.0 (ArC), 128.4 (ArC), 128.6 (ArC), 128.9 (ArC), 130.4 (ArC), 130.7 (ArC), 131.0 (ArC), 131.7 (ArC), 142.0 (ArC), 143.1 (ArC), 145.2 (ArC), 145.3 (ArC), 147.2 (ArC), 148.0 (ArC), 154.4 (ArC), 154.9 (CO) and 167.4 (CO) ppm. FABMS: m/z: 1783.6 (M⁺). $C_{98}H_{90}N_{14}O_{12}S_4$ (1784.1): calcd C 65.97, H 5.08, N 10.99. Found: C 65.78, H 5.51, N 10.82.

4.3. Determination of the Association Constants

The association constants were determined by using 1H NMR titration experiments in a constant concentration of host receptor $(4.0 \times 10^{-3} \text{ M})$ by varying the guest concentration $(0-8.0 \times 10^{-3} \text{ M})$. The 1H NMR chemical shift of the urea protons (NH) signal was used as a probe. The association constant (K_a) for the complexes of receptor $\mathbf{5}_{a-c}$ were calculated by nonlinear curve-fitting analysis of the observed chemical shifts of the NH protons according to the literature procedure. 14

.4. ¹H NMR Titration Experiments

A solution of Bu₄NX (X = F, Cl, Br, I, AcO, PhCOO, H_2PO_4) in CD₃CN (4.0 × 10⁻³ M) was added to a CDCl₃–DMSO (10:1, v/v) solution of receptor $\mathbf{5}_{\mathbf{a}\sim\mathbf{c}}$ in the absence or presence of AgSO₃CF₃ in an NMR tube. ¹H NMR spectra were recorded after addition of the reactants and the

temperature of the NMR probe was kept constant at 27 °C. The ¹H NMR data of the most-representative complexes are given below:

receptor $\mathbf{5}_a \supset Ag^+$: ¹H NMR (300 MHz, CDCl₃–DMSO–CD₃CN, 10:1:1, v/v): $\delta = 4.52$ (4H, br, C H_2 –triazole × 2), 4.94 (4H, s, OC H_2 CO × 2), 6.29 (4H, s, C H_2 –pyrene × 2), 7.13 (4H, s, Ar–H × 2), 7.34 (4H, s, Ar–H × 2), 7.54 (2H, br, N H_c × 2), 7.68 (2H, s, Triazole–H × 2) and 7.79–8.38. (18H, m, Pyrene-H × 18) ppm.

receptor $\mathbf{5}_b \supset \mathbf{Ag}^+$: ¹H NMR (300 MHz, CDCl₃–DMSO–CD₃CN, 10:1:1, v/v): $\delta = 4.56$ (4H, br, CH_2 –triazole × 2), 5.00 (4H, s, $OCH_2CO \times 2$), 6.32 (4H, s, CH_2 –pyrene × 2), 7.07 (4H, d, J = 8.8 Hz, Phenyl– $H \times 4$), 7.12 (4H, s, $Ar - H \times 2$), 7.30 (4H, d, J = 8.8 Hz, Phenyl– $H \times 4$), 7.48 (4H, s, $Ar - H \times 2$), 7.90 (2H, br, $NH_c \times 2$), 7.95 (2H, s, Triazole– $H \times 2$) and 8.00–8.41. (18H, m, Pyrene- $H \times 18$) ppm.

receptor $\mathbf{5}_{c} \supset \mathrm{Ag}^{+}$: ¹H NMR (300 MHz, CDCl₃–DMSO–CD₃CN, 10:1:1, v/v): $\delta = 4.52$ (4H, br, CH_2 –triazole × 2), 4.95 (4H, s, $OCH_2CO \times 2$), 6.32 (4H, s, CH_2 –pyrene × 2), 7.12 (4H, s, Ar–H × 2), 7.50 (4H, s, Ar–H × 2), 7.63 (4H, d, J = 8.8 Hz, Phenyl–H × 4), 7.69 (4H, d, J = 8.8 Hz, Phenyl–H × 4), 7.70 (2H, br, $NH_c \times 2$), 7.80 (2H, s, Triazole–H × 2), 8.02–8.30. (18H, m, pyrene-H × 18), 8.45 (2H, br, $NH_b \times 2$) and 8.98 (2H, br, $NH_a \times 2$) ppm.

receptor $\mathbf{5}_{c}$ Cl⁻: ¹H NMR (300 MHz, CDCl₃-DMSO-CD₃CN, 10:1:1, v/v): $\delta = 4.32$ (4H, br, CH_2 -triazole × 2), 5.00 (4H, s, $OCH_2CO \times 2$), 6.32 (4H, s, CH_2 -pyrene × 2), 6.72 (2H, s, triazole– $H \times 2$), 7.12 (4H, s, Ar– $H \times 2$), 7.33 (4H, s, Ar– $H \times 2$), 7.49 (4H, d, J = 8.8 Hz, Phenyl– $H \times 4$), 7.63 (4H, d, J = 8.8 Hz, Phenyl– $H \times 4$), 7.63 (4H, d, J = 8.8 Hz, Phenyl– $H \times 4$), 7.70 (2H, br, $NH_c \times 2$), 7.87–8.33. (18H, m, Pyrene- $H \times 18$), 8.41 (2H, br, $NH_b \times 2$) and 9.62 (2H, br, $NH_a \times 2$) ppm.

Ag⁺ ⊂ [receptor $\mathbf{5}_{c}$ ⊃Cl¯]: ¹H NMR (300 MHz, CDCl₃− DMSO–CD₃CN, 10:1:1, v/v): $\delta = 4.50$ (4H, br, CH_2 –triazole × 2), 5.00 (4H, s, $OCH_2CO \times 2$), 6.32 (4H, s, CH_2 –pyrene × 2), 7.12 (4H, s, Ar– $H \times 2$), 7.48 (4H, s, Ar– $H \times 2$), 7.63 (4H, d, J = 8.8 Hz, Phenyl– $H \times 4$), 7.69 (4H, d, J = 8.8 Hz, Phenyl– $H \times 4$), 7.86 (2H, br, $NH_c \times 2$), 7.94 (2H, s, Triazole– $H \times 2$), 8.02–8.30. (18H, m, Pyrene- $H \times 18$), 8.44 (2H, br, $NH_b \times 2$) and 9.60 (2H, br, $NH_a \times 2$) ppm.

Acknowledgments

This work was performed under the Cooperative Research Program of "Network Joint Research Center for Materials and Devices (Institute for Materials Chemistry and Engineering, Kyushu University)". We would like to thank the OTEC at Saga University and the International Cooperation Projects of Guizhou Province (No. 20137005) for financial support. The EPSRC is thanked for a travel grant (to CR).

Supplementary data

Electronic Supplementary Information (ESI) available: Details of the ¹H/¹³C NMR spectra, ¹H NMR and UV-vis titration

experimental data, the Bensei-Hilderbrand plot and Job's plot, See DOI: 10.1039/b000000x/
