10   **Abstract**

11   The unreliability of water supplies in developing countries is a widely recognized concern.

12   However, unreliability means different things in the variety of literature on water supplies, and no

13   unified definition or assessment criteria exist. We review definitions of water supply reliability

14   used in existing literature, as well as the various ways in which it is assessed. Thirty-three papers

15   were selected for review that reported on reliability of domestic water supply and if they were based

16   on empirical research in developing countries. Explicit definitions of reliability are given in four out

17   of the 33 papers reviewed. These definitions vary, but features common in them are the

18   functionality of the water supply system itself, and the extent to which it meets the needs of water

19   users. Assessment criteria also vary greatly, with the most common criterion in urban settings

20   being the duration / continuity of supply in hours per day, while in rural settings, the proportion of

21   functional water systems is commonly used. The heterogeneity in the definitions and assessment

22   criteria found in the review is perhaps indicative of a multi-attribute nature of the concept of

23   reliability and any unifying definition and assessment criteria might do well to take this into

24   account.

25

26   Keywords: water supply, reliability, definition, assessment criteria, review

27

1 Introduction

In 2012, an estimated 89 % of the global population had access to safe water, and the Millennium Development Goal (MDG) target of halving the proportion of the world's population by 2015 had seemingly been met (UNICEF/WHO, 2012). However, caution had already been noted that the indicator used to track progress against this target – 'use of an improved source' – did not sufficiently address some key aspects of water safety and access. A review estimated that 1.9 billion people use either an unimproved source, or an improved source with faecal contamination (Bain et al., 2014). Further – and of main interest in this review – is the note in the MDG update that reliability of water supply was not addressed in the existing indicator (UNICEF/WHO, 2012).

Estimates vary, but around 300 million people globally are thought to be served by piped water supplies that are intermittent, with supplies available for less than half the day (Kumpel and Nelson, 2016). Across rural sub-Saharan Africa, a third of hand-pumps are thought to be non-functional at any given time (Rural Water Supply Network, 2009).

Intermittent or unreliable water supplies and episodes of low pressure have been associated with increased risk of gastrointestinal illness (Hunter et al., 2005, Lechtenfeld, 2012, Majuru et al., 2011, Nygård et al., 2007). This may occur through among other things, intrusion of contaminants as a result of back-siphonage during pressure losses, or households using unsafe alternative water sources during supply interruptions. In addition, unreliable water supplies may also impact negatively on income, productivity and educational attainment (Kudat et al., 1993, Subbaraman et al., 2012) as houseolds – particularly women and children – often have to engage in labour- and time-intensive coping strategies (Majuru et al., 2016).

Unfortunately, robust literature on the scope of the problem of water supply reliability remains lacking. No unified definition nor measurement approach for water supply reliability exists (UNICEF/WHO, 2012), and the data that are available are often sketchy (Kleemeier, 2010). Much of the often-cited data on the reliability of water supplies for piped systems are from the World Bank's International Benchmarking Network for Water and Sanitation Utilities (IBNET, 2011). The database contains information on duration of supply in hours per day and / or proportion of residential customers receiving intermittent supply from utilities in 85 countries. Because the data are reported by the utilities themselves, the quality depends greatly on the accuracy of this reporting (UNICEF/ WHO, 2011).

Systematically collected data on the reliability of water supplies for non-piped systems – typically in rural or peri-urban communities – are even more limited. The most often cited figures are from the Rural Water Supply Network(Rural Water Supply Network, 2009), which are themselves a

34   compilation from various sources and report only on functionality of handpumps in sub-Saharan

35   Africa. Thus, the little systematic data that are available are often limited to specific communities,

36   regions or water supply technologies, and are sometimes not nationally representative.

37   The Sustainable Development Goals (SGDs) have now superseded the MDGs, and SDG 6 seeks to

38   ensure access to safe water and sanitation for all. The indicator for monitoring Target 6.1 on

39   drinking-water is: "the proportion of the population using safely managed drinking water services".

40   The 'safely managed' indicator comprises three criteria: the source should be located on premises;

41   water available when needed; and free from faecal and chemical contamination (World Health

42   Organization/United Nations Children's Fund (WHO/UNICEF), 2015). While water supply

43   reliability is captured under the availability criterion, the lack of harmonized definitions and

44   assessment approach has made aggregation of data across countries and over time difficult (World

45   Health Organization, 2017).

46   The aim of this paper is to provide a review of the various definitions and assessment criteria of

47   water supply reliability that has been used in the literature. It is hoped that this summary will

48   contribute to the identification of clearer definitions and assessment criteria that can be used to

49   evaluate the reliability of water supplies, particularly in developing countries.

50   **Methods**

51   Before describing the methods, we outline a conceptual overview of reliability of water supplies.

52   *A conceptual overview of water supply reliability*

53   As Galaitsi et al. (2016) note, the lack of a harmonized definition or assessment approach for water

54   supply reliability is perhaps reflective of the multi-faceted nature of the problem, as reliability can

55   be conceived in various ways. In their early studies on unreliability of water supplies and its impact

56   on households, Kudat and Humplick proposed that as commodity, water comprises three main

57   attributes: quantity, quality and pressure. Where these three attributes are not at their optimum level,

58   the water supply is said to be unreliable. Similarly, a proposed definition of reliability from IRC

59   (2011) is where the water supply meets quantity, quality and accessibility needs at a given time, and

60   is available within a known schedule ('punctuality of service'), even if is not continuous / 24 hour

61   supply. The IRC's proposed definition goes on to note that 'problematic services are characterised

62   by down time, significant breakdowns, and slow repairs'.

63   Taken together, these definitions suggest that: while it could be argued attributes such as quantity

64   and quality should be considered separately from reliability (World Health Organization, 2017,

65 Zérah, 1998), these attributes are interlinked; and reliability can be defined / assessed on a scale,
66 and is not necessarily a binary concept.

67 For the purposes of this review, we broadly consider reliability as a feature of water supply
68 comprising several interlinked attributes, including: continuity, e.g. available 24 hours a day every
69 day, or for part of the day on some days; predictability, e.g. supply not continuous, but available at
70 regular intervals; functionality e.g. breakdown in the system; and pressure, where fluctuations may
71 result in limited or no supply.

72 *Literature search methods and selection criteria*

73 Scoping searches can be described as brief searches aimed at mapping the existing literature, and
74 can be useful in refining research questions, potential resources required, clarification of terms
75 related to the research question, etc. (Armstrong et al., 2011). We conducted a scoping search prior
76 to the actual search for the review to identify the various terminology used in relation to reliability
77 in the water supply literature. Literature searches for grey and published literature were then
78 conducted in a number of databases and websites shown in Table 1.

79   Table 1 here

80 The search terms used in the academic databases were:

81 "water supply" OR "safe water" OR "drinking water" OR "domestic water" OR "household water"
82 OR "water point" AND reliab* OR sustainab* OR availab* OR function* OR regular OR access
83 OR intermitten* OR interrupt* OR constant OR continu* OR consistent OR "operation and
84 maintenance" OR breakdown

85 Where possible, searches were specified as title, abstract and keyword searches. It was not possible
86 to apply the exact search string amongst all the resources searched. In Google and Google Scholar,
87 three searches were conducted to cover the search string detailed above. Each of these searches
88 contained the terms relating to water (water supply etc.) and five of the terms relating to reliability,
89 until all the terms had been covered. Amongst the websites of non-governmental organisations and
90 donor agencies where the number of search terms was similarly limited, only the terms relating to
91 water were applied.

92 Papers retrieved from the search and were screened independently by two reviewers for relevance
93 according to the following criteria:

94 • Report on reliability of domestic water supply

95 • Based on primary data from developing countries

96 • Report on operational reliability of water supply, not water scarcity, e.g. due to drought

97 • Provide a definition and / or assessment criteria of reliability

98 The full texts of papers in English whose abstracts met the criteria were retrieved and reviewed in
99 detail. From Google and Google Scholar, the first 50 hits from each of the searches were checked
100 for potentially relevant papers. The reference lists of these included papers were also checked for
101 potentially relevant literature. Data from major national surveys of the Asian Development Bank
102 (ADB) and Pan American Health Organisation (PAHO) were also reviewed. We defined
103 developing (low and middle income) countries as per the World Bank classification.

Results

105 Seventy-eight documents were reviewed for this assessment and 33 were found to be relevant.
106 Amongst those excluded, reasons included lack of clarity on both how reliability was defined and
107 consequently assessed and results being presented as an overall index of sustainability, from which
108 data on reliability specifically could not be drawn. Two of the papers (Zerah, 1998; 2000) were
109 based on the same survey and were regarded as one paper for the purposes of the review.

110 Of the 33 papers reviewed, half were carried out in sub-Saharan Africa (Tables 2a-c). The data
111 from PAHO covered 19 countries in Latin America and the Caribbean region, while that from ADB
112 covered 40 utilities in Lao, Malaysia and Vietnam. Fifteen of the studies evaluated reliability in
113 rural settings, 13 in urban and five in both rural and urban settings. The ADB survey data from
114 south-east Asia was for utilities in urban areas, whereas that of PAHO covered both urban and rural
115 areas.

Definitions of reliability

117 Definitions or descriptions of reliability are explicitly stated in four papers. A list of these papers
118 and others in the review is given in Tables 2a-c. These definitions vary considerably, including:
119 "the physical absence of water flowing from the tap" (Howard, 2002); "availability of water at a
120 point of consumption (household or public stand-pipe) for 24 hours a day, 7 days a week, 365 days
121 a year" (Shah, 2003) and "a service is reliable if it is provided in time, and with the quality and
122 quantity required" (Zérah, 2000).

123 Although none of the definitions are shared by more than one paper, there is some degree of
124 commonality in the features used by the different studies as part of their definition. One is to define
125 reliability in terms of the water supply system itself and the extent to which it works (Admassu et

126 al., 2003, Howard, 2002). The other defines reliability in relation to the extent to which the needs

127 of water users are met ((Zérah, 1998, Zérah, 2000).

128 *Assessment of reliability*

129 The criteria used to assess reliability also differ somewhat. For example, Akosa (1990) quantifies

130 reliability as the "fraction of the time when the service is available to the user", while Kleemeier

131 (2000) reports on the "proportion of taps supplying water at time of survey and preceding 3

132 months". Some assessment criteria are shared by more than one paper and seem to be specific to

133 the setting, i.e. rural or urban:

134 The assessment criteria used in urban settings are presented in Table 3a. The most common

135 criterion used to assess reliability of water supplies in urban settings / piped systems is duration of

136 supply in hours per day. This criterion is used in 12 of the 18 studies reporting on urban settings

137 (Andey and Kelkar, 2009, Asian Development Bank, 2007, Baisa et al., 2010, Caprara et al., 2009,

138 Gulyani et al., 2005, Pan American Health Organization, 2001, Pattanayak et al., 2005, Shah, 2003,

139 Thompson et al., 2000, Virjee and Gaskin, 2010, Widiyati, 2011, Zérah, 2002, Zérah, 1998, Zérah,

140 2000, Jiménez and Pérez-Foguet, 2011).

141 Among the literature covering rural settings, seven papers (Admassu et al., 2003, Arnold et al.,

142 2013, Asian Development Bank, 2009, Davis et al., 2008, Jiménez and Pérez-Foguet, 2011, Pan

143 American Health Organization, 2001, World Bank - Netherlands Water Partnership, 2009) report on

144 the proportion of water sources functional at the time of the survey (Table 3b). Downtime (duration

145 of breakdowns in the water supply system) is reported in five of the papers (Arnold et al., 2013,

146 Asian Development Bank, 2009, Davis et al., 2008, Majuru et al., 2012, World Bank - Netherlands

147 Water Partnership, 2009).

148 Three of the papers report on ease of operation of handpumps. In a study in Zimbabwe, Hoko and

149 Hertle (2006) report that users had difficulty in operating handpumps, and in some instances up to

150 100 strokes were required before water was discharged. Similarly, Musonda (2004) finds that

151 women and children in particular sometimes had difficulty in collecting water from handpumps

152 because they were too stiff to operate.

153 *Lifespan of water supply systems*

154 Five papers assess reliability in relation to the age of water supply systems. Kleeimeier (2000)

155 evaluated the Malawi Rural Piped Water Scheme Program and reports that although the smallest

156 and newest schemes were performing well 3 to 26 years after completion, overall almost half of the

157   schemes were performing poorly. In a survey of 16 water points in a district in rural Zambia,

158   Musonda (2004) found that 10 years was the average age for functional handpumps, whereas semi-

159   functional hand pumps were approximately 13 years old or more. Functional handpumps were

160   those that typically served 360 people, whereas non-functional ones were those that had served

161   about 506 people. This correlation between age and functionality of water supply systems is also

162   reported by Moon (2006). Anecdotal evidence from the paper suggests that hand pumps require

163   major rehabilitation after 7-8 years. Most pump and engine systems have significant maintenance

164   costs within a few years but a few seem to work after 30 years, while gravity systems seem

165   relatively unaffected by age.

166   Jiménez and Pérez-Foguet (2011) surveyed water points in 15 districts covering 15 % of the rural

167   population in Tanzania. They find that functionality rates did not vary greatly between hand

168   pumps, gravity-fed systems and motorised pumping systems. Functionality of hand pumps dropped

169   from 61 % in the first five years of installation to 6 % over a period of 25 years. In the same period,

170   motorised pumps dropped from 77 % to 13 %, while gravity-fed systems dropped from 66 % to 20

171   %. The aggregated functionality for three technologies was 35-47 % of functional water points

172   after 15 years. The authors conclude that generally 30 % of water points became non-functional

173   within the first five years of operation, after which period the decrease in functionality is at a slower

174   rate.

175   In contrast, Bourgois et al. (2013) find that the performance of older systems is significantly better

176   than that of newer ones. In their survey of water points in three districts in Sierra Leone, 73 % of

177   the water systems that were 22 years old were functioning at the time of the survey, compared to 40

178   % of those that were a year old.

179   **Discussion**

180   We explored definitions of and criteria used to assess water supply reliability, and have also noted

181   some reports on the lifespans of various water supply technologies. We find that only four out of

182   33 papers in our review give explicit definitions of reliability. These definitions vary, but two

183   common features appear to underlie these definitions; the functionality of the water supply system

184   itself, and the extent to which it meets the needs of water users. The most common criterion used to

185   assess water supply reliability in urban settings is the duration / continuity of supply in hours per

186   day, whereas in rural settings the proportion of functional water systems is more commonly used.

187   Results from four out of five papers reporting on the lifespans of water supply systems indicate a

188   correlation between age and functionality; older systems are less likely to be functional. These

189   results are contradicted in one paper which finds better functionality amongst older systems.

190 Before we discuss the implications of these findings, there are some limitations to the review that
191 should be noted. Various terms synonymous with reliability are used in the literature, and although
192 we have attempted to capture this variation in terminology in our search terms, we cannot exclude
193 the possibility that some terms might have been missed. The papers retrieved must be considered in
194 the light of this limitation. Although the literature reviewed is not exhaustive, it does cover a wide
195 range of grey and published literature, including literature from key agencies in the water sector and
196 results from important multi-country monitoring activities.

197 The two features underlying the definitions of reliability are reflective of the conundrum that
198 characterises the assessment of other features of water supply. Should the definition and
199 subsequent assessment be based on a *binary* approach of whether the supply is reliable, accessible
200 or safe, or rather one that better reflects the *quality* of these water supply features?

201 The results indicate that current practice appears to favour assessment criteria based on the former
202 in rural settings, and the latter in urban settings. The most common assessment criterion that is
203 reported in rural settings is the proportion of water sources that are functional at the time of the
204 survey. Given that the majority of papers reviewed are from sub-Saharan Africa where the majority
205 of rural dwellers rely on handpumps (UNICEF/ WHO, 2011), it is likely that the assessment
206 approach might have been shaped on this basis.

207 There are some challenges that the approach presents. First, although handpumps are quite
208 common as the supply technology in rural areas, there are some countries that are making
209 significant progress in 'moving up the service ladder' by providing piped technologies, either at
210 communal points, within yards or within the home, South Africa being an example (see Tissington
211 et al., (2008, Lockwood et al., 2002)). In these settings water supply systems may not stop
212 functioning completely, but gradually deteriorate in performance, and failure to take this into
213 account would yield inaccurate estimates of the real situation on the ground.

214 Further, these 'snap-shots' of the proportion of functional systems do not always take into account
215 whether the breakdown is short-term, pending repair, or if the water source is completely non-
216 functional (Koestler et al., 2010, Lockwood et al., 2002). The difficulty in operating handpumps
217 that is noted as a significant problem in three papers perhaps alludes to the limitations of
218 considering reliability of handpump supplies as a binary issue of whether or not the pump works.

219 The dominance of a particular assessment criterion in a particular setting should also not be
220 assumed to mean that it is necessarily the most appropriate. For instance, although duration of
221 supply appears to be the de facto assessment criterion in urban settings, adequate water pressure for
222 instance, may also be important to water users. In the paper by Davis et al. (2008) the authors noted
223 discrepancies in the reported duration of breakdowns, and attributed the discrepancies to

224   respondents classifying events of low pressure that resulted in limited or no supply as breakdowns.

225   Other studies have found that pressure fluctuations in piped systems can negatively affect water

226   quality and subsequently health (Klasen et al., 2012, Lechtenfeld, 2012). Taking this into account

227   plus the range of assessment criteria found in this review, our findings point towards reliability of

228   water supply being a multi-attribute concept, and this should be reflected in the definition. The

229   adoption of a single assessment criterion also should not be assumed, and it is suggested that a

230   multi-criteria assessment approach may be more appropriate.

231   As efforts to refine indicators used for global monitoring continue, we highlight that the primary

232   challenge presented by water supply reliability is how to define and assess it in a framework that is

233   cognisant of:

234   •   the multi-attribute nature of water supply reliability

235   •   the various water supply technologies

236   •   the feasibility and cost of assessment

237   •   the role of water supply reliability as a predictor of health, social and economic outcomes

238   Evidently, the development of this framework and subsequent definition and assessment criteria

239   requires the continued collaborative efforts of those providing water supplies, funders and

240   monitoring agencies. To this, we would add that understanding the value water users place on

241   various attributes of reliability is necessary to better tailor assessment criteria that broadly recognise

242   user perspectives. Amongst the literature we reviewed, little account is given as to how the criteria

243   used to assess reliability were arrived at, nor how users define or perceive the concept of reliability.

244   **Conclusion**

245   Our review has shown that there is a lot of variation in the definitions and assessment criteria used

246   in literature on water supply reliability in developing countries. That said, there is some degree of

247   commonality in the assessment criteria used, depending on the setting. Much of the literature

248   reporting on urban settings report on duration of supply in hours per day, whereas in rural settings

249   the proportion of functional water supply systems is more commonly reported.

250   Although these particular criteria dominate in the existing literature, care should be exercised to not

251   assume that they are necessarily the most appropriate. First, the heterogeneity in the definitions and

252   assessment criteria used is perhaps indicative of a multi-attribute nature of the concept of reliability.

253   Failure to take this into account in the assessment process – regardless of setting – would likely

254   yield an inaccurate depiction of the situation. Secondly, the reliance on a binary indication of

255   functionality in rural settings may not take into account the changing landscape of water supply

256   technologies in these areas, where supply systems may not necessarily fail altogether but perform at

257   a sub-optimal level. Thirdly, there is no indication that the perspectives of water users – those

258   actually faced with unreliable water supplies – are taken into account when deciding upon

259   assessment criteria. As ensuring reliability becomes increasingly critical in achieving the goal of

260   universal access to water, the definition and assessment criteria for water supply reliability should

261   be thoughtfully selected and employed.

262   **Funding**

Table 2a: Literature on urban settings

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
Aderibigbe et al. 2008	Determine the availability, adequacy and quality of water supply	Urban Nigeria 750 female respondents randomly selected from 3 communities	Descriptive cross-sectional study, using structured questionnaires	None stated	62.9 % of respondents house connection	15 % had water more than 3 times a week 30.1 % had water 2 or 3 times a week 54.9 % had water occasionally or once a week
Andey & Kelkar 2009	Evaluate influence of continuous and intermittent water on domestic water consumption	Urban India, 4 cities; Ghaziabad: 35 households out of 48; Jaipur: 195 households out of 206; Nagpur: 214 households out of 330; Panji: 51 households out of 120 households	Six measurements repeated times over 1 year for both modes of supply. Average consumption calculated from meter readings, duration of survey and number of people in households	None stated	Piped supply	Ghaziabad: 10 hours/day Jaipur: 3 hours/day Nagpur: 16 hours/day Panji: 5 hours/day
Asian Development Bank, 2007	Help water utilities southeast Asia to assess their performance	Urban southeast Asia 2005 40 water utilities; 17 from Vietnam, 17 from the Philippines, 5 from Malaysia and 1 from Lao PDR.	Water utility questionnaire	None stated	Piped supply	24 hours a day on average for Malaysia and Lao; 23 hours a day on average for Vietnam and the Philippines
Ayoub & Malaeb 2006	Investigate impact of intermittent supply on water quality	Urban Lebanon 2003-2004 181 water samples	Quantitative. Samples collected from water network before storage in household tanks and after storage from household tanks	None stated	Piped supply	Once every two days

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
Baisa et al. 2010	i) Develop a model describing the optimal intertemporal depletion of each household's private water storage if it is uncertain when water will next arrive to replenish supplies ii) evaluate the potential welfare gains that would occur if alternative modes of water provision were implemented	Urban Mexico 2005 data	Model calibrated using data from the Mexican National Household Survey of Income and Expenditure survey	None stated	Piped supply	1 day per week: 2.8% 2 days per week: 2.1% 3 days per week: 3.8% 4 days per week: 0.2% 5 days per week: 1.3% 6 days per week: 0.2% Daily at limited hours: 21.6% Daily at all hours: 68.0%
Caprara et al. 2009	Investigate the relationship between the socio-economic characteristics and community practices that take place indoors (e.g. garbage disposal, water storage practices) affecting Ae. aegypti.	Urban Brazil 2005	Mixed methods. Purposive sampling of 6 blocks in city of Fortaleza 204 households total 51 middle class households 153 under-privileged households	None stated	Piped supply	*Middle class:* 2-5 dys/wk: 0; 6 -7 dys/wk: 39 (100%); 3-12 hrs/dy: 23 (59%); 13-24 hrs/dy: 16(41%) *Under-privileged class:* 2-5 dys/wk: 30 (21.4%); 6-7 dys/wk: 110 (78.6%), 3-12 hrs/dy: 37 (26.4%), 13-24 hrs/dy: 103 (73.6%)
Gulyani et al. 2005	Examine current water use and unit costs in three Kenyan cities and test the willingness of the unconnected to pay for piped water, yard connections, or an improved water kiosk (standpipe) service	Urban Kenya 2000 674 households interviewed in 22 sites in the three urban areas	Cross-sectional survey using structured questionnaires	None stated	House connection Yard tap Kiosk	House connection: 36%<8hrs/dy, 28% 8-16hrs/dy, 36%>16hrs/dy Yard tap: 47%<8hrs/dy, 32% 8-16hrs/dy, 21%>16hrs/day Kiosks: 36%<8hrs/dy, 54% 8-16hrs/dy, 10%>16hrs/dy.

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
Howard 2002	Develop a model of water supply surveillance for urban areas of developing countries that provides reliable assessment of water supplies, with particular emphasis on the urban poor	Urban Uganda 1997-200 1,652 water points in 10 locations	Multi-criteria zoning to identify vulnerable communities and structured observation of water points and structured questionnaires	Discontinuity was defined as being the physical absence of water flowing from the source	Piped water Point sources: protected springs boreholes/ tubewells with handpumps, dug wells with handpump	309 (18.7%) water points had discontinuity. Piped: 245 (25.7%); Protected: 33 (6.7%) Unprotected: 31 (15.1%). Discontinuity occasional (70%) seasonal interruption relatively common and daily/monthly interruptions far less common.
Mycoo 1996	Provide a demand-oriented perspective on water provision for domestic users, examining cost recovery potential based on household willingness to pay more for an improved service and water pricing	Urban Trinidad Stratified sampling of 6 settlements (total of 420, sampling rate 0.34%). Criteria: location, elevation and slope, income, housing and land tenure, level of service and the number of hours of water received.	Cross-sectional survey using contingent ranking, contingent valuation and observed behaviour of the household in producing water	None stated	Piped: House connection Yard tap Communal tap	4S% of customers receive a 24 hour supply seven days a week
Pattanayak et al. 2005	Evaluate how coping costs and willingness to pay vary across types of water users and income	Urban Nepal 2001 Clustered sampling (probability-to-size), 1500 households in five municipalities of Kathmandu Valley	Mixed methods cross-sectional survey using 17 purposive, open-ended discussions, 2 focus groups, and 150 pre-tests in designing the survey instrument	None stated	70% piped, 30%: private wells, public taps, stone spouts, and water vendors. About 1% of the connected households share a connection with other households	Water was available from private connections on average about 2 hours per day in the wet season and 1 hour per day in the dry season

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
Shar 2003	Establish the value of water supply services to people of Zanzibar Town by measuring willingness to pay for reliable water services, to provide basis for change of the financing policy for water supply services management.	Urban Zanzibar 300 households out of 10 Shehias; (0.94 % of the town's households). In some instances household shad to be targeted to balance political affiliations	Cross-sectional survey using structured questionnaire	Availability of water at a point of consumption (household or public stand-pipe) for 24 hrs a day, 7 days a week, 365 days a year.	Piped supply	20.7 % had 'no problem' with supply, 27% had water for 1-5 hrs/dy; 24.3% for 5-10hrs/dy; 13% 5-10hrs/dy; 12.7% for 15-24 hrs/dy; 0.3% did not respond and 0.7% did not know
Thompson et al. 2000	Assess changes in domestic water use	Urban Kenya, Tanzania, Uganda 1997 Unpiped households: 99 Piped households: 349	Cross-sectional follow up study, 30 years later, using semi-structured interviews, observation, interviews with key informants, , field observation, review of secondary literature	None stated	Piped in house connection	Water available 24hrs/dy: 56%, <12hrs/dy: approximately 40%; 1-5hrs/dy: approximately 20%
Virjee & Gaskin 2010	Ascertain the willingness to pay for changes in the level of service experienced by users	Trinidad and Tobago 2003 The Central Statistical Office's Continuous Sample Survey of Population sampling method was used to randomly select 1419 households, using a two-stage stratification scheme based on geography and labour force characteristics	Cross-sectional multi-part survey	None stated	WASA in-house piped connection only; WASA in-house connection + secondary source; No in-house connection	Water available 24hrs/dy, 7dys/week: 27%, Almost 30% received no water from WASA at all during the time of the survey. 68% had water storage tanks on their premises with an average installed capacity of 610 gallons. As a result of these coping mechanisms, 82% of those with tanks had a 24-hour water supply

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
Widiyati 2011	Present evidence of willingness to pay to avoid costs associated with intermittent water supply from Bandung Municipality in Indonesia	Urban Indonesia 2011 200 people interviewed in survey	Cross-sectional survey using structured questionnaires	None stated	Piped	24 hour supply: 60% For about 40%: water is rationed from 1hour every 2days to about 18 hours per day. Mean hours of supply in actual study was 2.4 based on a numbered scale of 1: ≤3hrs/day, 2:3-6hrs/dy, 3: 7-10hrs/dy, 4:11-13hrs/dy, 5:other
Zérah 1998, 2000	*Study 1:* Measure the costs of unreliability *Study 2:* understand the household demand for a service by assessing the actual behaviour adopted by households when they have to cope with an inadequate service.	Urban India 1995 Two stratified sample of 678 households in four zones of urban Delhi	Cross-sectional survey using structured questionnaires	A service is reliable if it is provided in time, and with the quality and the quantity required	Piped	On average, 13hrs/dy, about 40 % have water around the clock about 13 % do not get water at all; High pressure: 8.5%; Average pressure: 49.1% Low pressure: 32.9%; No pressure: 9.5% >12hrs: 50.3%; 6-12hrs:8.6%, 2-6hrs: 28.2%, ≤2hrs: 12.8%

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
Zérah 2002	Determine the level of service provided by the Vijayawada Municipal Corporation (VMC); assess the existing households' coping strategies; evaluate the cost of water supply and sanitation and measure the level of satisfaction of the inhabitants of Vijayawada	Urban India 2002 167 households in 15 wards (out of 50 wards) and in neighbouring villages of Vijayawada	Cross-sectional survey using structured questionnaires	None stated	Piped connections, private boreholes, public taps	Municipal water connection: 3.83 hours of supply in summer, 3.73 in winter Private boreholes: On an average, households spend almost 2 hours to pump water. Public taps: water is available every day in winter in 93% of the cases and in 96% of the cases in summer. Otherwise water is available on alternate days. In winter and in summer, supply is similar (around 6 hours).

Table 2b: Literature on rural settings

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
Admassu et al. 2003	Assess utilisation, functionality, community participation and sustainability of water projects	Rural Ethiopia, 2001-2002 11 randomly selected peasant associations, making a total of 768 households and 114 site observations	Descriptive cross-sectional study using structured questionnaires, observation and 4 focus group discussions	Functioning: proper physical state of water supply projects in relation to their present working condition at the time of the survey	Protected spring, hand-dug wells with pumps	52 out of 442 source points not functioning. (11.76%)
Arnold et al	Assess existing water infrastructure, determine the reliability of water sources, assess the water quality available for domestic use, and evaluate community awareness as related to water, sanitation, and hygiene.	Rural Ghana, 2008-2010 8 villages selected on basis on participation in previous community development projects and request by villagers	Cross-sectional surveys in summers of 2008-2010m using sanitary surveys, conversations with villagers, 1 focus group, key informant interviews and water quality testing	None stated	Standpipes, boreholes, dug wells and shallow wells	One third of standpipes not functioning at time of survey,
Davis et al. 2008	Explore the contribution of various types of post-construction support (PCS) to the sustainability of rural water supply systems in Bolivia	Rural Bolivia 2005 99 communities	Cross-sectional mixed methods using household survey, system operator survey, focus group with village leaders, focus group with women, focus group with village water committee	None stated	94 % had house connections or yard taps 27 % had public taps 8 % had wells	Breakdowns as reported by operators: mean 2, household members: mean 3, women's focus groups: mean 2.9 Typical duration of breakdowns (dys) operator: mean: 4.2, household members: 9.8, women's focus groups mean 15.8. Systems received prior to 2000, range between 5 and 8 years in age

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
Hoko & Hertle 2007	Evaluate the sustainability of a rural water point rehabilitation project that was carried by a local NGO	Rural Zimbabwe 144 water points Mwenezi: 37 Gwanda: 41 Bulilima: 38 Mangwe: 28	Cross-sectional quantitative study using structured observation of water points and structured questionnaires	None stated	Boreholes with handpumps	Water points not working in Mwenezi: 4%, Gwanda: 17%, Bulilima: 13% Mangwe: 25%. Operation of the water points deemed difficult by a minimum of 19% (Mwenezi) to a maximum of 64% (Mangwe) of respondents.
Jiménez & Pérez-Foguet, 2011	Establish relationships between technology, functionality and durability of rural water points	Rural Tanzania 2005-2006 5.921 water points 15 districts covering 15 % of rural population	Quantitative cross-sectional survey (Water Aid data)	None stated	Handpumps 2,326 (39.3%) Motorised pumping systems 2,180 936.8%) Gravity fed 1,263 (21.3%) Other (protected springs, rainwater-harvesting, windmill powered water point): 152 (2.6%)	*

*Functionality: Handpumps 45.31%, gravity -fed systems: 48.61% motorised pumps 44.36%, other systems: 36.18% Aggregated functionality: 45.4%.

Handpump functionality dropped from 61% in first 5yrs to 6% in the 25yr period: Motorised systems started at 77% and dropped to 13%, gravity fed systems 66% to 20%. Aggregated rate: 35-47% working 15 yrs after installation.

>30% of WP become non-functional after the first 5yrs and after this the functionality rate decreases at a slower rate (another 30% become non-functional in following 15yrs) - handpumps show least favourable functionality rate; gravity-fed show irregular trend between periods but best performance in the long-run; motorised pumping systems have a very good performance in the first period and maintain a similar descending slope as others in the long term

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
Kleemeier 2000	Explore the assumption about the link between participation and sustainability by presenting findings from a study of operation and maintenance on rural water supplies that were constructed under a program widely praised for its exemplary approach to community participation	Rural Malawi 1997-1998 Sample includes schemes from all three of Malawi's administrative regions. Sample limited to schemes that originally had less than 120 km of pipeline. 17 schemes visited for one day and a follow-up visit to four of the schemes	Cross-sectional survey involving discussion with water schemes' monitoring assistant, main committee, tap committees, repair teams and observation of schemes	None stated	Piped- communal taps	Overall, 66% of the taps supplied water a minimum of 50% of the days in the previous 3 months. In 4 of the smallest schemes (13-37 taps), 80% or more of the taps supply water on a regular, if not continuous basis
Majuru et al 2012	Assess the impact of unreliability on water service indicators of distance to source, water quantity and quality	Rural South Africa 2007-2008 3 communities of which one was a control/reference community, 114 households in total	Quasi-experimental with repeated cross-sectional surveys of water supplies and daily symptom diaries over 56 weeks	None stated	Piped- communal taps Drilled wells with handpumps Water tanks	Handpumps: broke down for about 2 weeks every 3 months; 83% ; Tanks: water ran out after 2 weeks: 50% Communal taps Community 1: 2 breakdowns 89%, Community 2: 4 breakdowns: 58%
Moon 2006	Assess the role of private sector participation in developing and sustaining rural water schemes	Rural Tanzania 2004-2006 6,812 distribution points in 3 regions and 1 district in another region	Quantitative cross-sectional survey (Water Aid data)	None stated.	Four commonly used extraction systems in the study area: pump and engine, Afridev handpumps, Tanira handpumps, and gravity systems.	Pump and engine schemes have a functionality rate of 48% and the others vary between 60% and 70%

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
Musonda 2004	Identify factors that contribute to the promotion of sustainability of rural water supplies in Zambia	Rural Zambia 2001 16 water points in Mazabuka District	Mixed methods cross-sectional survey with structured questionnaires and observations	None stated	Hand-dug well and boreholes with handpumps	8 functioning out of 16, 3 in disrepair for 2 months, 1 in disrepair for 4 years, 1 very difficult to operate, 3 functioning but had problems. Five years was the average age for functional handpumps, as they had been constructed between 1995 and 2000. All semi-functional handpumps had been constructed between 1980 and 1996
Norwegian Agency for Development Cooperation, 2008	Carry out a descriptive based analysis of Norad's previous support to the WSS sectors in partner countries, with emphasis on Kenya and Tanzania during the period 1975 - 1995	Rural Kenya and Tanzania	Archive search and literature study, single and group interviews cross-sectional field work	None stated	Kenya: piped water supply Tanzania: Handpumps, gravity schemes	*Rukwa:* between 65 % and 74 % of 2,000 water points still operating and in daily use. *Kigoma:* between 76 % and 78 % of 800 water points still working and in daily use. *Kenya:* 16 towns, 91 % of water points still working and in daily use.

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
Schweitzer 2009	Evaluate the efficacy of community management in sustainability of rural water supply	Rural Dominican Republic 2008-2009 Stratified random sample of 64 water systems built in the DR by initiatives of the National Institute of Potable Water (INAPA, 23) and Peace Corps (41) out of a total cohort of 185 (118 PC and 67 INAPA)	Mixed methods using secondary data analysis observation (participant and non-participant) focus group/key informant interviews household surveys formal versus informal interviews	None stated	INAPA (21): Public or shared taps 1%, Patio connections 77%, Household connections 9%, Multiple connections 14%; Peace Corps (40):Public or shared taps 6%, Patio connections 68%, Household connections 8%, Multiple connections 18%.	Systems with major repairs within last month: INAPA: 80 %, Peace Corps 45% Days per week with water INAPA: 5.7, Peace Corps: 6.2 Hours per day with water INAPA: 11.4, Peace Corps: 16.6 Average system age (years) INAPA: 5; Peace Corps: 6.85
World Bank – Netherlands Water Partnersrhip, 2009	Investigate how the provision of support to communities after the construction of a rural water supply project affected project performance in the medium term	Rural Peru, and Ghana. Peru mid 2004, Ghana late 2004 Peru: 99 villages, 25 households on each village, 1,360 male and 1,089 female respondents	Cross-sectional mixed methods using household survey, system operator survey, focus group with village leaders, focus group with women, focus group with village water committee	None stated	Handpumps, public taps and house connections	∞

∞Peru: Taps working (operator data): FONCODES Average: 95%; SANBASUR Average 93%; Average hours of operation/day (household data): FONCODES: 18.8; SANBASUR: 19.9; Average major unplanned interruptions in water supply service for at least one day in past 6 months (operator data): FONCODES: 89%; SANBASUR: 59%; (Leaders): FONCODES: 70%; SANBASUR: 55%; Average system age: FONCODES: 7.57 years; SANBASUR: 6.13 years; Average number of days to fix major problem operator: FONCODES: 4.53; SANBASUR: 1.06; leaders: FONCODES: 2.08; SANBASUR: 2.58

Ghana: % of villages where all project handpumps are working (89): Brong Ahafo: 88; Volta: 92; % villages with working systems that had a breakdown in last 6 months (57): Brong Ahafo: 58; Volta: 55; Average years since completion: Brong Ahafo: 6.2; Volta: 5.8 (Average 6); Median days to repair the system last time it broke (reported by hhs) (20): Brong Ahafo: 18; Volta: 22

Table 2c: Literature on both urban and rural settings

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
Akosa 1990	Develop of a Data Envelopment Analysis method to combine assessment of technical, financial, economic, institutional, social and environmental aspects of water supply and sanitation projects	Rural and urban Ghana, 1986-1988 6 water supply projects over a 30-month period	Cross sectional surveys with Observation, records from treatment plants, interviews with plant operators	None stated	Piped Drilled wells with handpumps Hand-dug wells with handpumps	*

*Accra-Tema Water Supply: Power outages involved 193 faults lasting a total of 707 hrs 7mm in 3 years (1986-88). Frequency of fault: 1 fault in 5.67 days. Duration: average 3.67 hrs/fault. Plant down time: 2.7%.

Borehole Water Supply: 21.7% down time.

Package Plant Water Supply: 20.3 % down time. % of time when plant was operating with inadequate supply of chemicals (including periods of chemical rationing) 58.7%.

2500 Drilled Wells Water Supply: Target established is 90% of pump operational at all times. Achievement is 85% of all handpumps operational. Down time is 15%.

3000 Drilled Well Water Supply: Target established is 90% of pumps operating at all times. Achievement is 40% of all hand pumps operational. Down time is 60%.

Hand Dug Well: Pump down time is calculated as 2.3% but water is available through the hatch

Asian Development Bank, 2009	Assess project performance and identify lessons for maximizing the development effectiveness of water supply and sanitation interventions, by conducting rigorous impact evaluation	Rural and urban Punjab, Pakistan. 7 randomly selected districts of the 30 covered by the Punjab Rural Water Supply & Sanitation Project (PCWSSP) and the Punjab Community Water Supply & Sanitation Project (PCWSS). 115 subprojects were identified using stratified random sampling, A total of 1,301 treatment households covered by a project and 1,301 comparison households outside the projects	Mixed methods using key informant interviews, focus group discussions, and household surveys. Comparison communities identified using district census reports. Community-level parameters used for matching: i) total village area ii) number of households with potable water iii) average household size iv) literacy rates.	None stated	92 % of the project communities had a community water supply system, while 8% of comparison communities did. 24% depended on hand pumps in project areas and 54% than in the comparison communities 40 % served by tube wells in project communities and 24 % in comparison communities	89% PCWSSP functional, and 68 % of PRWSSP Households receiving water received on average 5 hours of supply per day. 18 % of households in project areas used suction machines to deal with low pressure. Down time less than 3 days for 2/3 of major repairs
Bourgois et al., 2013	Survey of the quantity and quality of existing water access points in three districts in Sierra Leone	Rural and Urban Sierra Leone 2,859 drinking water access systems in 3 districts	Survey of water points and interviewers with local leaders of villages	None stated.	Spring box : 2 bore hole : 499 Hand dung well : 2028 Open well : 330	30 % of the finished, complete borehole systems were non-functional due to a broken pump

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
O'Hara et al. 2008	Quantify current level of access to safe water and sanitation in rural and urban communities across the Republic of Kazakhstan.	Rural and urban Kazakhstan 2005 7,515 people (0.05% of the population)	Cross-sectional in-depth questionnaire survey administered to7,515 people; 250 semi-structured interviews with individuals from urban and rural settlements, as well as officials working in various organisations concerned with water supply and health issues; and 16 focus group discussions with a range of stakeholder groups	None stated	Piped	Urban dwellers report service cuts on 6 days a month for 8-10 hours per day. Rural dwellers report cuts of 15-16 hours on an average of 21 days a month. People living in upper floors of high-rise buildings have cut-offs due to low pressure

Author(s), year	Objective(s)	Setting, year and sample	Methods	Definition of reliability/synonym	Type of supply	Estimates of (un)reliability
Pan American Health Organisation, 2001	Monitor and evaluate the situation of drinking water and sanitation in the Region of the Americas	Rural and urban parts of the Americas[*]	Questionnaires collation of information already existing in the countries, through consultations of documents and reports of entities of the sector and government institutions, results of household surveys, applied research and Sectoral Analysis or other pertinent studies conducted in the sector.	None stated	Piped and un-piped	Urban systems provided with water intermittently: 0 -100% Urban population provided with water intermittently: 0-99.9 % Rural systems in operation: 6-100%

[*]Countries covered in the survey were: Anguilla, Antigua & Barbuda, Argentina, Bahamas, Barbados, Belize, Bolivia, Chile, Colombia, Costa Rica, Cuba, Dominica, Dominican Republic, Ecuador, El Salvador, French Guiana, Grenada, Guadalupe, Guatemala, Guyana, Haiti, Honduras, Montserrat, Nicaragua, Panama, Paraguay, Peru, Puerto Rico, Saint Kitts & Nevis, Saint Lucia, Suriname, Trinidad & Tobago, Turks & Caicos Islands, Uruguay, Venezuela and Virgin Islands
