I. NATURE OF THE INVESTIGATION  
The purpose of this study is to determine the effect of the treatment of the soil on the growth of the plant. The results of the study are as follows:  
1. The growth of the plant is significantly higher in the treated soil than in the control soil.  
2. The yield of the plant is significantly higher in the treated soil than in the control soil.  
3. The nutrient content of the plant is significantly higher in the treated soil than in the control soil.  
4. The water content of the plant is significantly higher in the treated soil than in the control soil.  
5. The root length of the plant is significantly higher in the treated soil than in the control soil.  
6. The root diameter of the plant is significantly higher in the treated soil than in the control soil.  
7. The root volume of the plant is significantly higher in the treated soil than in the control soil.  
8. The root surface area of the plant is significantly higher in the treated soil than in the control soil.  
9. The root length to diameter ratio of the plant is significantly higher in the treated soil than in the control soil.  
10. The root volume to surface area ratio of the plant is significantly higher in the treated soil than in the control soil.

... many students have found it necessary to withdraw from college prior to graduation. The amount of tuition have been very slight for many of them. Others have obtained college credits from correspondence courses. In some cases additional training has been made available to students who are unable to attend college in person.

The National University Extension Act, which the University of New Mexico has administered since 1915 in order to provide instruction in various situations. In 1928, considerable attention was given to this university and correspondence courses were developed which allowed many people who were unable to attend university courses to get the degree of Bachelor of Science. Since 1928 correspondence courses have been developed in various fields including the study of the history of New Mexico.

These courses are administered by the University of New Mexico and frequently hold additional correspondence courses. Correspondence courses are available in many fields.

## CHAPTER I

### NATURE OF THE INVESTIGATION

Interruptions and cessation of planned programs have been perennial problems in the work of students from the earliest days of collegiate education. Many unforeseen difficulties account for these problems. For various reasons, many students have found it necessary to withdraw from college prior to graduation. The chances of return have been very slight for many of them. Others who have obtained college degrees have discovered later the need for additional training but have been unable to leave their employment to attend college in residence.

The National University Extension Association, of which the University of New Mexico is a member, was established in 1915 in order to offer service to people in like situations. In 1924 extension classes were established by this university and correspondence courses in 1928. These courses allowed many people who were unable to attend the university campus to pursue their educational programs. Since 1928 approximately sixty-five hundred people have availed themselves of this service from the University of New Mexico alone.

When something new or different is initiated people frequently hold conflicting ideas regarding the outcome. Controversy over the establishment of correspondence

courses and extension classes was a typical example of this outcome. Differences of opinion arose regarding the comparative quality of academic performance of students enrolled in residence and those in extension. However, no objective study has yet been made at the University of New Mexico comparing the academic performance of students in extension with that made by resident students, hence those differences of opinion have not been reconciled. In order to shed some light on the issue, this problem has been undertaken.

#### I. THE PROBLEM

Statement of the problem. The purpose of this study is to compare the academic achievement as measured by grade-point averages of (1) students in residence with their achievement in correspondence courses; (2) students in residence with their achievement in extension classes; (3) students in extension classes with their achievement in correspondence courses; and (4) to compare general student achievement as measured by grade-point averages of the same students in all three conditions of enrollment namely, residence, extension classes, and correspondence courses.

It is not the intent of this study to show or attempt to prove superiority of either extension or resident credit as measured by grade-point average. It is only to compare the relative achievement made by the same students when

enrolled in residence and extension as measured by the marks received.

Delimitation of the problem. This study is limited to data compiled from records of students who completed either one year or one semester and two summer sessions in residence at the University of New Mexico. Furthermore, only such records of students which indicated at least two correspondence and two extension class courses through extension were included.

Importance of the problem. In the opinion of some educators the academic performance of students in extension work is inferior to work done by them in residence. Others believe, however, that the achievement of students in extension classes is as good as, and sometimes better than, their achievement in residence.

The problem involved seems to be an important one. Because the amount of extension credit which can be applied toward a college degree is limited, this study should provide evidence for more intelligent determination of bases for such limitation.

Furthermore, concerning the matter of maintaining present practices and procedures or attempts to improve such practices and procedures in the University's Extension Division, results of an investigation like this should be of considerable value. There seems reason to believe also

united in business and industry to develop the  
national position.

Development of the Nation  
to date showed that a number of things had happened  
either one year or the other and that the  
results of the business of the nation  
only such results as the nation had to face  
consequently and the nation had to face  
consequently were included.

Development of the Nation  
education the students and the nation

to the nation to develop the nation

BOND

4

that the needs and rights of college students in extension and correspondence work should be considered. It would be difficult to justify a program of course work for such persons that was definitely inferior to that done in residence. This in turn implies a need for, first, making every effort to ascertain the relative quality of the work offered under the various conditions of enrollment, and second, for applying the information obtained directly to the problem of offering a superior quality of work in each of these conditions of enrollment. Thus, consideration of the needs and rights of students working in correspondence courses and extension classes seems to give further evidence of the importance of this problem.

## II. DEFINITIONS OF TERMS USED

Extension courses. In this study the term extension courses includes both extension classes and correspondence courses.

Extension classes. During the academic school year classes are conducted by university-approved personnel in certain communities, towns, and cities of the state. These are called extension classes and are attended by people wishing to further their education who cannot attend the University in residence. In other words, the teacher goes to the students rather than having them come to the teacher.

FOR AGRICULTURE

BOARD

U.S.A.

DEPARTMENT OF AGRICULTURE

The Board has been organized to study the needs and conditions of the agricultural laborer in the United States. It is composed of representatives of the various agricultural interests and of the public. The Board has held several public hearings and has received many suggestions from the public. It is now preparing a report on the subject of the needs and conditions of the agricultural laborer. The report will be published in the near future.

The Board is now holding public hearings on the subject of the needs and conditions of the agricultural laborer. The hearings are being held in various parts of the country. The Board is interested in hearing from all interested parties. The hearings will continue until further notice.

The Board is now holding public hearings on the subject of the needs and conditions of the agricultural laborer. The hearings are being held in various parts of the country. The Board is interested in hearing from all interested parties. The hearings will continue until further notice.

Only those courses listed in the general university catalog are offered in this manner. The instruction should be as thorough as that given in residence. Credits earned in this manner may be applied toward an undergraduate or graduate degree to the extent of forty semester hours and six semester hours respectively.

Correspondence courses. At any time during the year an individual may further his education by enrolling in university courses by mail. Such courses are planned and conducted by qualified university professors who teach the same courses to resident students. The correspondence course lessons are mailed to the student along with the textbooks and instructions for each lesson. The student then completes the lessons and returns them by mail. His marks are based on achievement resulting from his own initiative. Credits received in this manner may be applied toward an undergraduate degree to the extent of thirty semester hours. These courses are administered entirely by correspondence and are rightfully termed correspondence courses.

Resident student. Any student who has enrolled at the University of New Mexico for classes on the campus and has completed either one year of work or one semester, plus two summer sessions, is classified in this study as a resident student.

Grade-point average. In this study it was necessary to use a common means of comparison for the three different methods of obtaining academic credits, namely, residence, extension class, and correspondence course. Each course allows a stated number of semester hours toward a degree and, in addition, grade points are given in accordance with the marks achieved. The mark of A will give the student three points for each hour of credit, B will give two points, C will give one, and D carries no grade points.

To arrive at the grade-point average the total grade points are divided by the total number of credits earned. At the University of New Mexico a student must have at least one grade point for each credit counting toward graduation in order to receive a degree.

### III. SOURCES OF THE DATA

Data for this study were compiled from the records on file in the offices of the University Registrar and the Director of Extension.

### IV. METHODS OF PROCEDURE

This study is based on a total of 380 records of students selected from fifteen thousand transcripts originally examined. The 380 cases represented were divided into three categories. The first division contained

Grade-point average. The student's grade-point average is calculated on the basis of the number of credits earned and the number of credits attempted. The student's grade-point average is calculated on the basis of the number of credits earned and the number of credits attempted.

In addition, the student's grade-point average is calculated on the basis of the number of credits earned and the number of credits attempted. The student's grade-point average is calculated on the basis of the number of credits earned and the number of credits attempted.

To receive a grade-point average, the student must have earned a minimum number of credits. The student's grade-point average is calculated on the basis of the number of credits earned and the number of credits attempted.

At the University of the Pacific, the student's grade-point average is calculated on the basis of the number of credits earned and the number of credits attempted. The student's grade-point average is calculated on the basis of the number of credits earned and the number of credits attempted.

For this purpose, the student's grade-point average is calculated on the basis of the number of credits earned and the number of credits attempted. The student's grade-point average is calculated on the basis of the number of credits earned and the number of credits attempted.

This study is based on the student's grade-point average. The student's grade-point average is calculated on the basis of the number of credits earned and the number of credits attempted.

eighty cases based on records of students who had the necessary residence work and who, in addition, had completed at least two extension classes and two correspondence courses. The second division contained 130 cases based on records of students who had completed the necessary residence work and at least two extension classes. The final division comprised 170 cases. These were based on records of students who had completed the necessary residence work and at least two correspondence courses.

The cases were tabulated on a master sheet to show credits and grade points earned for residence, extension classes, and correspondence courses. In order to make further comparisons from which additional information could be gathered, the data were distributed on the basis of graduates, undergraduates, and sex. From the credits and grade points earned, grade-point averages were computed rather than using the letter grades, A, B, C, D, I, and F for each student.

Coefficients of correlation were obtained for the grade-point averages attained by each student. The correlation was between (1) grade-point averages in residence and in correspondence courses; (2) grade-point averages in residence and extension classes; and (3) grade-point averages in extension classes and in correspondence courses.

It was deemed necessary to procure additional in-

formation from which a further comparison could be made of marks earned by students in the three conditions of enrollment. There were eighty students who had obtained credits by all three methods. Graphs were compiled for these students to see how their marks compared with those attained by students in residence and correspondence, and also with grades received by students in residence and extension class.

It also seemed feasible to obtain as much other information as possible that would help to clarify the problem in question. Grade-point averages attained in residence by all pupils, men and women, on the undergraduate level were compared with those obtained on the graduate level. Comparisons were also made of records of men and women in the distribution. First, the residence grade-point averages of all men were compared with the residence grade-point averages of all women. Next, residence grade-point averages of undergraduate men were compared to residence grade-point averages of graduate men. Also, a comparison was made of the residence grade-point averages of undergraduate women and graduate women.

The same types of comparisons were made of grade-point averages attained in extension classes and also in correspondence courses. From these statistical data, observations were made and conclusions drawn.

## V. ORGANIZATION OF THE REMAINDER OF THE STUDY

A previous study of this kind had never been made at the University of New Mexico. Several other colleges and universities throughout the United States, however, have compiled somewhat similar information for their own institutions. Chapter II will deal with a discussion of the findings of other universities on the subject.

Presentation of the statistical analysis derived from student transcripts at the University of New Mexico will compose Chapter III.

In Chapter IV, the conclusions and recommendations developed from this study will be summarized.

7. COMPARISON OF THE RESULTS OF THE TEST

A previous study of this kind has never been made at the University of New South Wales. Several other universities, however, have completed research similar in type to that of this study. Chapter II will deal with a discussion of the findings of other universities in the subject.

Presentations of the statistical analysis derived from student transcripts at the University of New South Wales will compose Chapter III.

In Chapter IV, the conclusions and recommendations developed from this study will be presented.

## CHAPTER II

### REVIEW OF RELATED LITERATURE

The earliest establishment of correspondence and extension class work was in 1909. Since that time colleges and universities which offer credit by extension courses have carried on a variety of studies in an attempt to compare achievement in correspondence and extension class with the same student's achievement in residence. Most of the related studies have been undertaken by the Extension Divisions of various institutions throughout the United States. These studies will be reviewed here. In addition, the findings from an unpublished Master's thesis from the University of New Mexico will be presented.

Study by R. E. Crump.<sup>1</sup> The plan of investigation that Crump decided upon was to select certain subjects which were taught by the same instructor in the three methods of instruction. Each instructor evaluated his students three different times during the term. A test was given at the beginning of each course. At a specified interval during the term a second test was made and a final examination was administered at the conclusion of the course.

---

<sup>1</sup> Robert Edward Crump, Correspondence and Class-Extension Work in Oklahoma (Southeastern State Teachers College Contributions to Education, No. 1. Durant, Oklahoma; Southeastern State Teachers College, 1928), pp. 46-67.

Initial intelligence of the students was tested by the Otis Self-Administering Intelligence Tests -- Higher Form A. These tests were selected because of their reliability, ease of administration, and ease of scoring. Crump took into consideration the fact that professors may vary from term to term in methods of instruction and this, in turn, may affect a student's concomitant learnings. He obtained cooperation from the instructors to insure consistency throughout the term.

The three methods of conducting classes were set up in seven different courses on the campuses of different colleges in Oklahoma. The total number of students for each course was divided into three groups, each group taught by a different method but by the same instructor. Each student was required to record actual time needed for the preparation of lessons. When the courses were completed students were equated by the McCall method. Crump concluded that class extension and correspondence work was on a par with residence instruction.

The study by Crump, although excellent in all respects, is not entirely parallel to the conditions of this writer's study. Crump had a controlled situation. All of his students were on the campus. They were divided into three groups, each receiving instruction by a different method, namely, residence, correspondence, and extension

class. The marks used by this writer for his study were earned by students taking correspondence courses from the University of New Mexico, regardless of where they happened to reside and marks earned by students in extension classes held in any section of the State where there was enough interest to warrant holding a class. Ages, abilities, and job experience background of such students are by no means the same.

Study by Clem Oren Thompson.<sup>2</sup> In his work, The Extension Program of the University of Chicago, Thompson made a detailed study of the abilities of extension students. He did not obtain any objective measures of the abilities of extension students. They were not required to take any of the intelligence examinations. Thompson presented two measures, however, that could be used for comparison. The first was between marks received by students in extension and students in residence. The second comparison was the relative homogeneity of marks earned by groups of students enrolled in extension and residence. In presenting the conclusions, Thompson stated:

When correspondence study students come to the Quadrangles to work the difference between the mean quality of their undergraduate work and of all un-

dergraduate work on the Quadrangles is  $.41 \pm .015$  grade points in their favor; when extension class study students come to the Quadrangles and work the difference between the means of their undergraduate work and all undergraduate work on the Quadrangles is  $.52 \pm .02$  in their favor.<sup>3</sup>

Study by Alfred Lawrence Hall-Quest.<sup>4</sup> In his book, The University Afield, Hall-Quest stated that instructors for extension teaching should, beyond the shadow of a doubt, be the best material the University can afford. Its professors are sent into the smallest communities where libraries are few and instruction facilities meager. It is then up to the teacher "to put his subject across" in the best possible way under existing conditions.

He also stated that many Universities are jealous of their resident enrollments and do not allot as large a sum of money for expansion of extension divisions as could be used in most cases. In such institutions the enrollment is held down more by the unavailability of courses for extension study than by the incapability of students studying by extension.

<sup>3</sup> Ibid., p. 51.

<sup>4</sup> Alfred Lawrence Hall-Quest, The University Afield (New York: The Macmillan Company, 1926), pp. 166-84.

Initial intelligence of the students was tested by the Otis Self-Administering Intelligence Tests -- Higher Form A. These tests were selected because of their reliability, ease of administration, and ease of scoring. Crump took into consideration the fact that professors may vary from term to term in methods of instruction and this, in turn, may affect a student's concomitant learnings. He obtained cooperation from the instructors to insure consistency throughout the term.

The three methods of conducting classes were set up in seven different courses on the campuses of different colleges in Oklahoma. The total number of students for each course was divided into three groups, each group taught by a different method but by the same instructor. Each student was required to record actual time needed for the preparation of lessons. When the courses were completed students were equated by the McCall method. Crump concluded that class extension and correspondence work was on a par with residence instruction.

The study by Crump, although excellent in all respects, is not entirely parallel to the conditions of this writer's study. Crump had a controlled situation. All of his students were on the campus. They were divided into three groups, each receiving instruction by a different method, namely, residence, correspondence, and extension

class. The marks used by this writer for his study were earned by students taking correspondence courses from the University of New Mexico, regardless of where they happened to reside and marks earned by students in extension classes held in any section of the State where there was enough interest to warrant holding a class. Ages, abilities, and job experience background of such students are by no means the same.

Study by Clem Oren Thompson.<sup>2</sup> In his work, The Extension Program of the University of Chicago, Thompson made a detailed study of the abilities of extension students. He did not obtain any objective measures of the abilities of extension students. They were not required to take any of the intelligence examinations. Thompson presented two measures, however, that could be used for comparison. The first was between marks received by students in extension and students in residence. The second comparison was the relative homogeneity of marks earned by groups of students enrolled in extension and residence. In presenting the conclusions, Thompson stated:

When correspondence study students come to the Quadrangles to work the difference between the mean quality of their undergraduate work and of all un-

Study by Herbert Sorenson.<sup>5</sup> In the paper, "The Abilities of Extension Students," presented by Sorenson in May, 1933, to the National University Extension Association, he declared the typical extension student to be as well qualified in scholastic ability and better qualified from a maturity standpoint and job experience background than resident students. He also stated:

Extension students generally achieve more in proportion to their measured aptitudes than do residence students.<sup>6</sup>

Sorenson said that if this fact is expressed in the terminology of educational psychology, one could say that the extension students have higher accomplishment quotients than resident students. These relatively higher achievements are due to the fact that study and learning are more real and vivid to those students who are mature. Experience gives a vitality to classroom and laboratory work that young, inexperienced people lack.

Second Study by Herbert Sorenson.<sup>7</sup> In the study

<sup>5</sup> Herbert Sorenson, "The Abilities of Extension Students," Proceedings of the Eighteenth Annual Convention of the National University Extension Association, Vol. 16, 1933, pp. 35-40.

<sup>6</sup> Ibid., p. 38.

<sup>7</sup> Herbert Sorenson, Adult Abilities in Extension Classes (Minneapolis, Minnesota: The University of Minnesota Press, 1933), pp. 29-64.

that Sorenson made on Adult Abilities in Extension Classes, he found that the abilities of women extension students in the Minnesota Reading Test and Minnesota College Aptitude Test were markedly higher than those of men extension students, except at the upper extreme. In the same tests extension students, including both men and women, had more ability than college freshmen, slightly less ability than juniors and seniors in the Minnesota College Aptitude Test, and slightly higher ability than juniors and seniors in the Minnesota Reading Test.

Sorenson also made the statement that when one considers the theory that mental growth normally ceases somewhere between the ages of thirteen and eighteen, any additional abilities attained by the individual must accrue from school or job experience. This would tend to suggest that the average extension student would have better general college ability than most college freshmen.

Study by Arthur J. Klein.<sup>8</sup> In the article, "Correspondence Study in Universities and Colleges," Klein reported some of the facts concerning the extent and use of the correspondence method of instruction by reputable institutions, and to show how these institutions carry on

---

<sup>8</sup> Arthur J. Klein, Correspondence Study in Universities and Colleges (Bulletin of the United States Office of Education, 1920, No. 10. Washington, D. C.: United States Government Printing Office, 1920), pp. 1-33.

the work in such a way that its educational value can not be questioned. In summarizing statements from seventy-three institutions contributing to the study, Klein stated:

It is common testimony of institutions that students in residence who have taken work by correspondence ordinarily rank in the upper fourth of their classes.<sup>9</sup>

He also stated that the results of questionnaires distributed by the different colleges and universities showed that students then enrolled in residence thought correspondence courses required more rigid discipline to prepare lessons before turning them in. The students indicated that they could let residence work "slide along" until time for examinations and then "cram."

Klein believed that this would tend to explain why the largest percentage of students who complete correspondence study are a select group in that they do not drop out but put more time on lesson preparation and have the perseverance to finish the course.

Study by Russell M. Grumman.<sup>10</sup> In the book, University Extension in Action, Grumman stated that at Chapel

---

<sup>9</sup> Ibid., p. 28.

<sup>10</sup> Russell M. Grumman, University Extension in Action (Chapel Hill, North Carolina: The University of North Carolina Press, 1947), pp. 25-48.

Hill, North Carolina, the best instructors are encouraged to carry part of the load of correspondence and extension subjects. It was felt from the very beginning of extension work that good instructors were necessary to keep instruction on as high a level as possible. Grumman's only mention of extension students' abilities was that a good many of them came to Chapel Hill to complete work for their degree and experienced no difficulty in doing so.

Study by J. O. Marberry.<sup>11</sup> An entirely different approach to the same problem was presented by Marberry in his study, Extension Teaching in the University of Texas as Viewed by the Student. Students who had received instruction in both residence and extension were given questionnaires to complete. The questionnaires asked for comparisons between courses taught in residence and similar courses taught by extension. From the tabulated answers Marberry concluded that higher ratings were given in extension teaching in more than one-third of the cases reported and about the same as residence instruction in more than one-half of the total. The remaining number, approximately one-sixth of the total, said residence instruction was superior to that given by extension.

Marberry commented that probably these were students who had received low marks in extension work.

Study by William Henry Zeigel.<sup>12</sup> In Zeigel's work, The Relation of Extra-Mural Study to Residence Enrollment and Scholastic Standing, he found from a study of 4141 enrollments for the years 1919 to 1923 inclusive in residence and extra-mural (correspondence and class extension) classes that residence grades are a much better index of extra-mural grades than extra-mural grades are of residence grades. He also found that when grades in all three types of instruction were compared, they ranged in every instance as follows: (1) residence marks were lowest; (2) extension marks were grouped around the middle point; and (3) correspondence marks were highest.

Another interesting fact discovered by Zeigel was that students who had both residence and extension study, or residence and correspondence study, always made higher grades in residence than did students with residence study alone. Conversely, students' grades in extra-mural studies were higher when residence work was also being taken than when extra-mural work was taken alone.

Study by Walton S. Bittner and Hervey F. Mallory.<sup>13</sup>  
In the book, University Teaching by Mail, Bittner and Mallory made a study of eight institutions, all members of the National University Extension Association. Their conclusions were that correspondence students frequently comprise a select group with superior persistence and perhaps superior ability or that they have gained superior habits of study at home or at school. Of the hundreds of students who enroll for correspondence work to obtain university credit, the average is not more than three correspondence courses, or an average total of nine credits for all who graduate.

This fact should not affect the accredited ratings of any university or college. Students who find the work by correspondence more difficult than they expected, drop out. Those who complete courses are of the group with superior persistence and ability. Students working for a degree usually present only a small number of credits earned by correspondence to apply toward graduation. Institutions should never fear that such students' work is below average, for it is usually above.

Bittner and Mallory also stated that correspondence study is not advocated as a substitute for residence study

---

Efficient and ... study in ...

... study in ...

but as a supplement to it. If anyone completes, by correspondence, as much as one third of the semester hours required for graduation, he should be admired for the perseverance shown. Such people also tend to raise the academic standards.

When speaking of ratings of students taking work by residence as compared to home study, Bittner and Mallory stated:

The majority of students who undertake study at home are earnest and ambitious and their records show the expected results. The graduates of eight institutions in 1928 and 1929, who earned a part of their credits by correspondence study, won more honors than those who had done all their work in residence.<sup>14</sup>

It was also suggested by Bittner and Mallory that an instructor of correspondence courses must possess a very different combination of qualities than the instructor for residence work. An instructor for correspondence study must have resourceful imagination to meet situations arising concerning the individual student who must necessarily depend upon written communication for his assignments and instructions. The instructor must be one of the best the institution can offer.

---

<sup>14</sup> Ibid., p. 23.

but as a supplement to it. It is more complete, by course  
sometimes, as much as one third of the necessary parts for  
entire for evaluation, he should be added for the purpose  
various shows. Such people also tend to raise the standards  
standards.

When speaking of ratings of students taking work in  
testimony as compared to home study, Hiltner and Heltzer  
stated:

The majority of students who undertake work at  
home are earnest and ambitious and their results  
show the expected results. The grades of about  
institutions in 1928 and 1929, who earned a grade  
of their credits by correspondence study, was more  
honors than those who had done all their work in  
testimony.

It was also suggested by Hiltner and Heltzer that  
an instructor of correspondence courses must possess a  
very different combination of qualities than the instructor  
or for residence work. An instructor for correspondence  
study must have exceptional facilities to meet them.  
Some advice concerning the individual student who must  
necessarily depend upon written communication for his as-  
signments and instructions. The instructor must be one of  
the best the institution can offer.

Study by W. Barnie Caton.<sup>15</sup> In the thesis, "A Study of the Extension Division of the University of New Mexico, with Emphasis on the Period 1928-1938," Caton concluded that the quality of work performed by both extension class and correspondence were on a high level. The grades earned by correspondence students were slightly lower than grades earned by extension class students. Both, however, were higher than the normal curve.

---

<sup>15</sup> W. Barnie Caton, "A Study of the Extension Division of the University of New Mexico, with Emphasis on the Period 1928-1938," (unpublished Master's thesis, The University of New Mexico, Albuquerque, 1938), p. 99.

Study of the Expansion Division of the University of New  
 Mexico, with emphasis on the period 1928-1933, a study  
 which included the quality of work performed by post-graduate  
 students and correspondents were on a high level. The  
 grades earned by post-graduate students were slightly  
 lower than grades earned by extension class students.  
 Both, however, were higher than the general average.

## CHAPTER III

### PRESENTATION OF STATISTICAL ANALYSIS

One method of evaluating student achievement is measurement of the scholastic standing the individual attains. Under scholastic standing are included both rank in marks received and advancement in terms of semester hours of credit. It is admitted that the ranking of students, as revealed by marks, varies widely from professor to professor, subject to subject, and from semester to semester. There are also many methods of analyzing statistical data, the selection of which is dependent upon the purpose for which it is to be used. The writer has elected to use graphs, the mean, the standard deviation, correlation, and critical ratio as methods of studying the groups to see what differences, if any, exist in marks attained by the same students in residence, correspondence, and extension class. The presentation which follows will include relative facts as measured by grade-point averages and the discussion of certain assumptions which could be made about these relationships.

To help clarify the comparisons for the reader all discussion, figures, and tables will be consolidated into three groups, A, B, and C. Group A will be comprised of (1) all students, both men and women and graduates and

undergraduates, who have received marks in residence, correspondence, and extension class study; (2) all men, both graduates and undergraduates, who have received marks by the three methods of instruction; and (3) all women, both graduates and undergraduates, who have received marks by the three types of study.

Group B is made up of (1) all graduates, both men and women; (2) graduate men; and (3) graduate women. All three subgroups are divided according to the method of instruction from which their marks were earned.

Group C is made up of (1) all undergraduates, both men and women; (2) undergraduate men; and (3) undergraduate women. With Group C, as in Groups A and B, the subgroups are further divided according to the three different methods of instruction.

Analysis of Group A. The first comparison will be between grade-point averages earned in residence and by correspondence. Figure 1 portrays graphically marks earned by 250 students who completed work by both methods of instruction. It will be noted that the two curves are markedly different. The curve representing the residence grade-point averages is fairly regular. On the other hand, the correspondence graph-line is very irregular, with the two distinct peaks forming a bi-modal curve. It seems to be the procedure for instructors to evaluate students on

understanding, who have received their in residence,  
understanding, and extensive study; (2) all men,  
both graduates and undergraduates, who have received credit  
by the three methods of instruction; and (3) all women,  
both graduates and undergraduates, who have received credit  
by the three types of study.

Group 2 is made up of (1) all graduates, both men  
and women; (2) graduates men and (3) graduate women. All  
these subjects are listed according to the method of in-  
struction from which their credit was earned.

Group 3 is made up of (1) all undergraduates, both  
men and women; (2) undergraduate men; and (3) undergradu-  
ate women. With Group 2, as in Group 1, the sub-  
jects are further divided according to the three different  
methods of instruction.

Analysis of Group 1. The first analysis will be  
between graduate-level subjects earned in residence and  
correspondents. Table 1 reports frequency tables derived  
by 2x2 methods and compiled from the data listed in the  
table. It will be seen that the two methods are very  
highly different. The three correspondents are  
graduate-level women in table 1, and the other half  
the correspondence groups are in table 2. With the  
two distinct groups being a distinct matter. It seems to  
be the procedure for instruction to evaluate students in

FIGURE 1

DISTRIBUTION OF GRADE-POINT AVERAGES EARNED IN RESIDENCE AND CORRESPONDENCE BY 250 STUDENTS

the basis of A's, B's, C's, D's, or F's and therefore, when translated into grade points, the marks given inevitably fall into the 3.0, 2.0, 1.0, and 0.0 groupings. Most marks which students attain tend to congregate at either the 1.0 or 2.0 categories depending upon the interest in the subject, capabilities of the student, and marks given by the instructor, all of which tends to produce a bi-modal curve.

It is very likely that some students who enroll in correspondence courses complete the work because they are actually interested. In residence, a set course of study is outlined for each student, varying with the college in which he is enrolled. In the latter case many courses are required which are of no particular interest to the student, and, therefore, his marks may suffer accordingly.

There are two types of people who enroll in correspondence courses. Students in the first group select those courses which are to their liking and which are compatible with their established vocational or avocational interests. Students in the second group apply for correspondence courses for several reasons. Some may wish to obtain courses which count toward graduation but which they failed to obtain while in residence. Others may wish to obtain a teacher's certificate and need special courses to qualify. Still others may need courses to secure a

particular position. Changes in the industrial world require others to review a prescribed list of courses in order to keep pace. Students in this second group do not have the incentive to apply themselves and are probably the ones who receive the lowest marks indicated in Figure 1.

Figure 2 shows a comparison of grade-point averages earned by 210 students enrolled in both residence and extension class courses. In Figure 2, as well as in Figure 1, the residence grade-point averages follow very similar paths. The extension class graph-line shows a definite bi-modal tendency which, also, can probably be explained by the commonly practiced evaluation of students' work.

Another comparison in this group was between the grade-point averages earned by eighty students enrolled in both correspondence and extension class study. It will be seen in Figure 3 that correspondence and extension class grade-point averages follow the same lines very closely. It will be noted, however, that there are more students who received marks below the 1.6 grade-point average in correspondence than in extension class.

A second method of analysis of Group A is the use of the mean and standard deviation. It is shown in Table I that in all cases the mean is higher for correspondence and extension class grade-point averages than for residence

particular position. Changes in the individual world re-  
 quire others to review a prescribed list of courses in  
 order to keep pace. Students in this second group do not  
 have the incentive to apply themselves and are probably  
 the ones who receive the lowest marks indicated in Figure

1.

Figure 5 shows a comparison of grade-point averages  
 earned by 210 students enrolled in both residence and ex-  
 tension class courses. In Figure 5, as well as in Figure  
 4, the residence grade-point averages follow very similar  
 paths. The extension class graph-line shows a definite  
 bimodal tendency which, also, can probably be explained  
 by the commonly practiced restriction of students' work.

Another comparison in this group was between the  
 grade-point averages earned by night students enrolled  
 in both correspondence and extension class study. It will  
 be seen in Figure 3 that correspondence and extension  
 class grade-point averages follow the same lines very  
 closely. It will be noted, however, that there are some  
 students who received marks below the 2.0 grade-point  
 average in correspondence than in extension class.

A second method of analysis of Figure 1 is the use  
 of the mean and standard deviation. It is shown in Table  
 I that in all cases the mean is higher for correspondence  
 and extension class grade-point averages than for residence

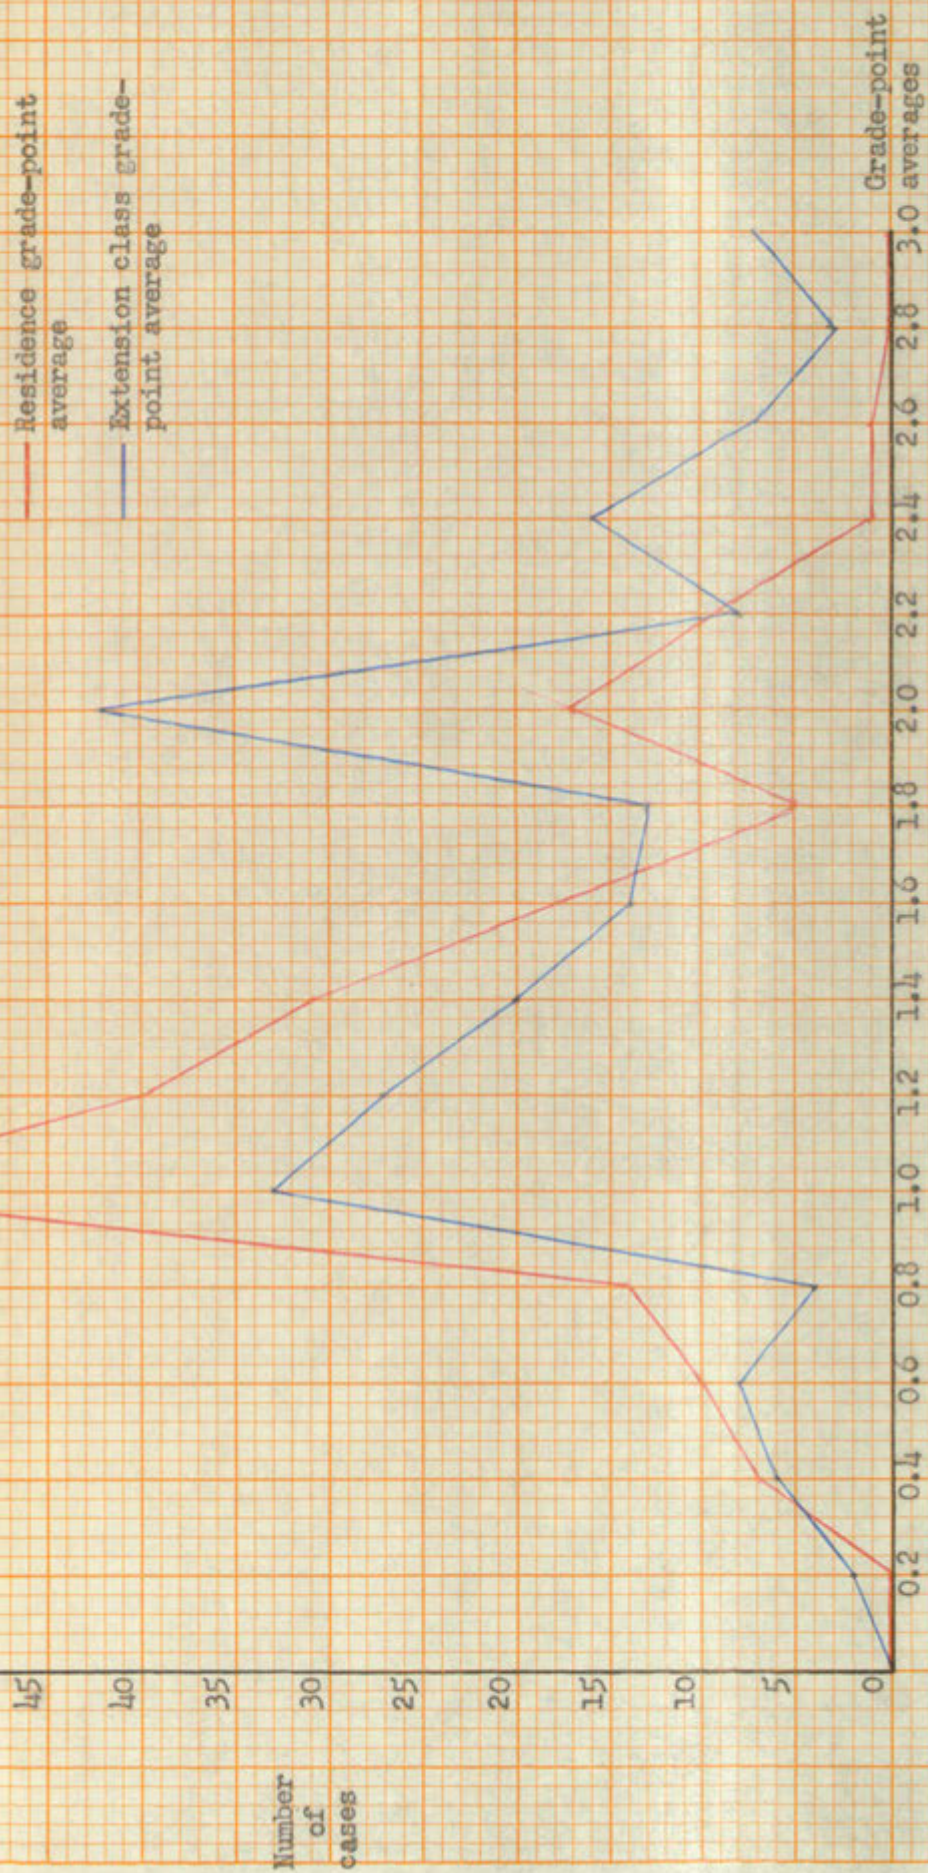

FIGURE 2

DISTRIBUTION OF GRADE-POINT AVERAGES EARNED IN RESIDENCE AND EXTENSION CLASS BY 210 STUDENTS

FIGURE 5

FIGURE 3

DISTRIBUTION OF GRADE-POINT AVERAGES EARNED IN CORRESPONDENCE AND EXTENSION CLASS BY 80 STUDENTS

PRODUCTION OF DEVIDS-KOJIMA VARIETY INHIBITORS IN DIFFERENT PHASES OF DEVELOPMENT AND MATURATION OF THE PLANT

TABLE 3

Production of inhibitors

study. Table I also shows that the extension class mean for men is lower than the correspondence mean. This seems to indicate that, on the average, men do not make as high marks in extension class as they do in correspondence. The table also indicates that women make higher marks than men in all three methods of instruction.

The reader will note from Table I that the standard deviation of least magnitude is .44 and of greatest, .68. The difference of .24 is only slightly more than one-fifth of the difference between any two letter marks, and thus indicates that the range of approximately two-thirds of the middle scores is quite consistent.

TABLE I

RELATIVE ACHIEVEMENT AS MEASURED BY GRADE-POINT AVERAGES OF THE MEAN, PROBABLE ERROR OF THE MEAN, AND STANDARD DEVIATION FOR GROUP A

Group A	Mean	Probable error of the mean	Standard deviation
1. All Students			
Residence	1.41	.0160	.47
Correspondence	1.65	.0281	.66
Extension class	1.70	.0295	.64
2. Men			
Residence	1.36	.0264	.44
Correspondence	1.56	.0516	.68
Extension class	1.43	.0458	.58
3. Women			
Residence	1.46	.0204	.48
Correspondence	1.68	.0335	.65
Extension class	1.85	.0358	.62

study. Table I also shows that the extension class mean for men is lower than the correspondence mean. This seems to indicate that, on the average, men do not make as high gains in extension class as they do in correspondence. The table also indicates that women make higher gains than men in all three methods of instruction. The reader will note from Table I that the standard deviation of least magnitude is  $\frac{1}{2}$  and of greatest,  $\frac{3}{8}$ . The difference of  $\frac{1}{8}$  is only slightly more than one-fifth of the difference between any two latter values, and thus indicates that the range of approximately two-thirds of the middle scores is quite consistent.

TABLE I

RELATIVE ACHIEVEMENT AS MEASURED BY GRADE-POINT AVERAGES OF THE MEAN, PROBABLE ERROR OF THE MEAN, AND STANDARD DEVIATION FOR GROUP A

Group A	Mean	Probable error of the mean	Standard deviation
1. All Students	1.71	.0160	.36
	1.67	.0221	.36
	1.70	.0297	.68
2. Men	1.36	.0224	.44
	1.36	.0216	.68
	1.47	.0178	.35
3. Women	1.46	.0200	.44
	1.65	.0177	.44
	1.52	.0236	.68

Another method of comparison used was the coefficient of correlation (see Appendix). Table II shows a positive correlation of  $.688 \pm .0220$  between residence and correspondence grade-point averages. Garrett<sup>1</sup> in his table states:

r from .00 to  $\pm .20$  denotes indifferent or negligible relationship;  
 r from  $\pm .20$  to  $\pm .40$  denotes low correlation; present but slight;  
 r from  $\pm .40$  to  $\pm .70$  denotes substantial or marked relationship;  
 r from  $\pm .70$  to  $\pm 1.00$  denotes high to very high relation.<sup>2</sup>

TABLE II

CORRELATION AND PROBABLE ERROR BETWEEN RESIDENCE, CORRESPONDENCE, AND EXTENSION CLASS FOR GROUP A

Group A	Correlation	Probable error
Residence and correspondence	.688	.0220
Residence and extension class	.694	.0240
Correspondence and extension class	.715	.0373

<sup>1</sup> Henry E. Garrett, Statistics in Psychology and Education (second edition; New York: Longmans, Green and Company, 1946), pp. 341-358.

<sup>2</sup> Ibid., p. 342.

Another method of comparison used was the coefficient of correlation (see Appendix). Table II shows a positive correlation of .683 between responses and correspondence grade-point averages. Correlation in the

Table states:

r from  $\frac{1}{2}$  to  $\frac{3}{4}$  .50 denotes indication of negligible relationship;  
 r from  $\frac{3}{4}$  to  $\frac{5}{8}$  .40 denotes low correlation present but slight;  
 r from  $\frac{5}{8}$  to  $\frac{3}{4}$  .30 denotes substantial or marked relationship;  
 r from  $\frac{3}{4}$  to  $1.00$  denotes high to very high relationship.

TABLE II  
 CORRELATION AND PROBABLE ERROR BETWEEN RESPONSES, CORRESPONDENCE, AND EXTENSION CLASS FOR GROUP A

Group A	Correlation	Probable error
Responses and correspondence	.683	.0280
Responses and extension class	.694	.0270
Correspondence and extension class	.712	.0265

<sup>1</sup> Henry H. Garrett, *Statistics in Psychology and Education* (second edition), New York: McGraw-Hill Company, 1946, pp. 361-362.

There are positive correlations of  $.694 \pm .0240$  between residence and extension class grade-point averages and  $.715 \pm .0373$  between correspondence and extension class grade-point averages. All three of the computations show marked relationship.

None of these correlations is high. They are high enough, however, to indicate that any similar group receiving high marks through one method of instruction would very likely receive high marks through either of the other two methods. Since there are many extenuating circumstances which affect marks earned by students, a positive coefficient of correlation of .6 may be regarded as quite significant.

In order to substantiate the preceding comparisons compilation of critical ratios were utilized. Good<sup>3</sup> explains critical ratio to be a statistical measure of the reliability of a sample, since the results for another sample may be entirely different. Good states:

The computed value is simply a probable value. Reliability of a measure is its tendency to remain constant for various samples.<sup>4</sup>

Statistically, the definition of critical ratio is the computed difference between the two means divided by

---

<sup>3</sup> Warren R. Good, An Introduction to Statistics (Ann Arbor, Michigan: The Ann Arbor Press, 1936), pp. 24-35.

<sup>4</sup> Ibid., p. 471.

There is a significant correlation between the two variables, as indicated by the Pearson product-moment correlation coefficient of .75, which is significant at the .01 level (two-tailed test). The regression equation is  $Y = 1.5X + 2.5$ , where Y is the dependent variable and X is the independent variable. The coefficient of determination is .56, indicating that 56% of the variance in Y is explained by X.

One of the main objectives of this study was to determine the relationship between the two variables. The results of the study indicate that there is a strong positive correlation between the two variables. This suggests that as the independent variable increases, the dependent variable also tends to increase.

The statistical analysis was conducted using the Pearson product-moment correlation coefficient. The results of the analysis are presented in the following table. The correlation coefficient is .75, which is significant at the .01 level (two-tailed test). The regression equation is  $Y = 1.5X + 2.5$ .

The results of the study indicate that there is a strong positive correlation between the two variables. This suggests that as the independent variable increases, the dependent variable also tends to increase. The regression equation is  $Y = 1.5X + 2.5$ .

The correlation coefficient is .75, which is significant at the .01 level (two-tailed test). The regression equation is  $Y = 1.5X + 2.5$ . The coefficient of determination is .56, indicating that 56% of the variance in Y is explained by X.

the probable error of the difference of the two means. Unless the computed critical ratio has a magnitude of 4.0 or greater, the true difference between the measures may be zero, and is thus not significant. Significance means a true difference, or a difference greater than zero, which is not due to the element of chance in the sampling.

The critical ratio, Table III, was found to be 7.2 for the difference between the means of residence and correspondence grade-point averages, and 8.5 for the difference between the means of residence and extension class grade-point averages for all students in the study. Also, the critical ratio for women was found to be 5.8 for the difference between the means of residence and correspondence grade-point averages, and 9.5 for the difference

TABLE III  
CRITICAL RATIOS FOR GROUP A

Critical ratio for the difference between two means for Group A		
	Residence and correspondence	Residence and extension class
All students	7.2	8.5
Men	3.4	1.3
Women	5.8	9.5

between the means of residence and extension class grade-point averages. Thus, the critical ratios of such magnitude indicate that the true difference between the means is significantly greater than zero and the computed difference is not due to chance of the sampling involved.

Table III indicates that the critical ratio for the difference between the means of residence and correspondence grade-point averages for men was 3.4. This is not large enough to insure significance, but according to the table presented by Garrett,<sup>5</sup> 98.9 times out of one hundred, the computed difference is not due to chance. The critical ratio for the difference between the means of residence and extension class for men was 1.3. The probabilities in this case are that eighty-one times out of one hundred the computed difference is not due to chance. Broken down still more, it could be said that there are only two chances out of ten that the results would be changed by different sampling.

Summary for Group A. To summarize briefly, comparisons for Group A, containing all students' grade-point averages, it may be said that this study indicates:

1. Correspondence grade-point averages are generally higher than those in residence.

---

<sup>5</sup> Garrett, op. cit., p. 471.

2. Extension class grade-point averages are generally higher than those in residence.

3. Extension class grade-point averages are slightly higher than those by correspondence.

4. Grade-point averages for women are generally higher than grade-point averages for men.

Analysis of Group B. Figure 4 is a graphic comparison of marks earned by 97 graduate students who have completed work by both residence and correspondence study. Graduate students include all students who have attained at least a Bachelor of Science or a Bachelor of Arts degree. It will be noted that grade-point averages earned by students in correspondence for Group B are much higher than those earned in residence. Approximately 60 per cent of the correspondence students earned grades of B or above. On the other hand only 22 per cent of the residence grades were B or above. A possible explanation for this is that even though these particular students have a degree, they are enrolled in correspondence courses to satisfy a thirst for something new, or are interested in special courses bearing upon their vocational or avocational pursuits, which in turn has a favorable effect upon the marks earned. Correspondence courses may not be taken for graduate credit.

Figure 5 presents a comparison between residence and extension class grade-point averages earned by sixty-three graduate students. In this instance the largest grouping

- 4. Grade-point averages for women are generally higher than grade-point averages for men.

**Analysis of Group 2. Figure 4 is a typical example.**

son of marks earned by 77 graduate students who have completed work by both residence and correspondence study. Graduate students include all students who have attained at least a Bachelor of Science or a Bachelor of Arts degree. It will be noted that grade-point averages earned by students in correspondence for Group 2 are much higher than those earned in residence. Approximately 60 per cent of the correspondence students earned grades of B or above. On the other hand only 25 per cent of the residence grades were B or above. A possible explanation for this is that even though these particular students have a degree, they are enrolled in correspondence courses to satisfy a deficit for something new, or are interested in special courses dealing upon their vocational or avocational pursuits, which in turn has a favorable effect upon the marks earned. Correspondence courses may not be taken for graduate credit. Figure 5 presents a comparison between residence and extension class grade-point averages earned by sixty-three graduate students. In this instance the largest grouping

of grade-point averages occurs at the 2.0 grouping, as was the case for the correspondence grade-point averages. An explanation similar to that given for the correspondence groupings in Figure 4 can probably be given for extension class. The residence grade-point average groupings for Figure 4 and 5 follow the same general patterns. The residence work is made up of courses required for graduation. Interest varies from student to student in each of these courses. It is quite likely that the assigned marks reflect this interest.

Figure 6 is a comparison of correspondence and extension class grade-point averages earned by thirty graduate students. In this case, there is very little difference in achievement as measured by marks received between these two methods of instruction.

The second method of comparison for Group B is use of the mean. Table IV indicates that grades which were received from extension courses are higher in every case than grades received in residence.

In comparing Table IV with Table I, it is clearly shown that the grade-point averages of graduates in residence, correspondence and extension classes are higher in each case than for all students taken together. Also for each method of instruction women received, on the average, better marks than men. The earned extension marks of men

in Group B correspond to those of men in Group A. Men received, on the average, better marks by correspondence than through extension class.

TABLE IV

RELATIVE ACHIEVEMENT AS MEASURED BY GRADE-POINT AVERAGES OF THE MEAN, PROBABLE ERROR OF THE MEAN, AND STANDARD DEVIATION FOR GROUP B

Group B	Mean	Probable error of the mean	Standard deviation
1. All graduates			
Residence	1.54	.0254	.43
Correspondence	1.95	.0287	.56
Extension class	1.92	.0504	.59
2. Graduate men			
Residence	1.48	.0423	.42
Correspondence	1.91	.0709	.60
Extension class	1.73	.1006	.65
3. Graduate women			
Residence	1.57	.0315	.43
Correspondence	1.99	.0497	.59
Extension class	1.99	.0575	.56

Correlations (see Appendix) of grade-point averages for Group B are presented in Table V. It will be seen that there is a positive correlation between averages of each of the groups listed. The correlation between residence and extension class grade-point averages is somewhat lower than the correlations for the other two.

A coefficient of correlation of  $.584 \pm .0568$  still

In Group 3 corresponding to Group 2, the mean is 1.50 and the standard deviation is 0.10. The correlation between the two groups is 0.80.

TABLE IV

RELATIVE MOVEMENT AS MEASURED BY GRADE-POINT AVERAGE OF THE HEAT, PROBABLE ERROR OF THE MEAN, AND STANDARD DEVIATION FOR GROUP 2

Group 2	Mean	Probable error of the mean	Standard deviation
1. All students	1.50	0.05	0.10
Residence	1.50	0.05	0.10
Correspondence	1.50	0.05	0.10
Extension class	1.50	0.05	0.10
2. Graduate men	1.50	0.05	0.10
Residence	1.50	0.05	0.10
Correspondence	1.50	0.05	0.10
Extension class	1.50	0.05	0.10
3. Graduate women	1.50	0.05	0.10
Residence	1.50	0.05	0.10
Correspondence	1.50	0.05	0.10
Extension class	1.50	0.05	0.10

Correlations (see Appendix) of grade-point averages for Group 2 are presented in Table V. It will be seen that there is a positive correlation between averages of each of the groups listed. The correlation between residence and extension class averages is somewhat lower than the correlations for the other two. A coefficient of correlation of .75 ± .05 will

denotes substantial relationship, however. The correlations for the other two sections are about the same, suggesting marked relationship.

TABLE V  
CORRELATION AND PROBABLE ERROR BETWEEN RESIDENCE,  
CORRESPONDENCE, AND EXTENSION CLASS  
FOR GROUP B

Group B	Correlation	Probable error
Residence and correspondence	.644	.0400
Residence and extension class	.584	.0568
Correspondence and extension class	.648	.0541

In order to substantiate the comparisons utilized in Group B critical ratios were again computed. The results are presented in Table VI. The critical ratios for all sub-groups except for graduate men are more than 4.0. It can be said with a high degree of confidence that the obtained differences between means are significantly greater than zero and that they did not arise through chance alone. The difference between the means of residence and extension class grade-point averages for this sub-group is 2.3. This is not large enough to insure a true difference and may be due to chance sampling.

indicated substantial relationship, however, the correlation  
coefficients for the other two conditions are about the same,  
suggesting marked relationship.

TABLE 2

CORRELATION AND PAIR-WISE TESTS BETWEEN  
CORRESPONDENCE AND EXTENSION CLASS  
FOR GROUP 2

Condition	Correlation	Significance
Residence and correspondence	.44	.05
Residence and extension class	.37	.05
Correspondence and extension class	.42	.05

In order to substantiate the correlation obtained  
in Group 2 ordinal ratios were again computed. The re-  
sults are presented in Table VI. The ordinal ratios for  
all sub-groups except for extension and extension class.  
It can be said with a high degree of confidence that the  
obtained differences between means are statistically  
greater than zero and that they did not arise through  
chance alone. The difference between the means of resi-  
dence and extension class groups is significant for this  
sub-group is 2.3. This is not lower than the critical  
two differences and may be due to chance sampling.

Ninety-four times out of one hundred, however, the computed difference is not due to the group sampled.

TABLE VI  
CRITICAL RATIOS FOR GROUP B

Critical ratio for the difference between two means for Group B		
Group B	Residence and correspondence	Residence and extension class
All graduates	8.9	6.9
Graduate men	5.2	2.3
Graduate women	7.1	6.4

Summary for Group B. In summarizing comparisons for Group B, containing the grade-point averages for all graduates, it may be said that this study indicates:

1. Correspondence grade-point averages are generally higher than those in residence.
2. Extension class grade-point averages are generally higher than those in residence.
3. Correspondence grade-point averages are slightly higher than those by extension class.
4. Grade-point averages for women are generally higher than grade-point averages for men.

Analysis of Group C. The first comparisons for Group C are portrayed graphically by Figures 7, 8, and 9. Figure 7 is the distribution of grade-point averages earned by 153 undergraduate students who have completed study by residence and correspondence. Three definite peaks appear in the correspondence grade-point graph-line. The groupings at 0.4 and 1.0 may be explained by the fact that the students in this group are all undergraduates and many may possibly have enrolled for correspondence courses in order to catch up with their class. They might have been more interested in getting the courses completed than in assimilating the material. Many students who enroll in residence do not graduate for many years and some never complete the total requirements for graduation. A large number, however, enroll for special courses and make above-average grades. The abilities of different students vary. A course that is difficult for one may be easy for another. Interest in the subject, associated learnings and above-average abilities may explain increases at the 2.0 and 3.0 groupings.

The residence graph-lines in Figures 7 and 8 follow the same general curves. The extension class groupings, Figure 8, have a pattern very similar, however, to the extension class pattern in Figure 2. They are bimodal with large numbers appearing in the 1.0 and 2.0

groupings.

Figure 9 reveals that undergraduates received lower marks in correspondence than by extension class. The discipline of study necessary for correspondence work may not have been adequately initiated.

The means for Group C which are shown in Table VII have a definite placing. In all sub-groups the extension class mean holds the highest grade-point average. The correspondence grade-point mean is next highest. The residence grade-point mean is the lowest in all cases.

TABLE VII

RELATIVE ACHIEVEMENT AS MEASURED BY GRADE-POINT AVERAGES  
OF THE MEAN, PROBABLE ERROR OF THE MEAN,  
AND STANDARD DEVIATION FOR GROUP C

| Group C                | Mean | Probable error<br>of the mean | Standard<br>deviation |
|------------------------|------|-------------------------------|-----------------------|
| 1. All undergraduates  |      |                               |                       |
| Residence              | 1.32 | .0207                         | .48                   |
| Correspondence         | 1.44 | .0343                         | .63                   |
| Extension class        | 1.61 | .0352                         | .63                   |
| 2. Undergraduate men   |      |                               |                       |
| Residence              | 1.21 | .0320                         | .43                   |
| Correspondence         | 1.22 | .0655                         | .65                   |
| Extension class        | 1.31 | .0459                         | .50                   |
| 3. Undergraduate women |      |                               |                       |
| Residence              | 1.40 | .0262                         | .50                   |
| Correspondence         | 1.51 | .0410                         | .63                   |
| Extension class        | 1.79 | .0448                         | .64                   |

The coefficients of correlation (see Appendix) between the grade-point averages for the three methods of instruction are presented in Table VIII.

TABLE VIII  
CORRELATION AND PROBABLE ERROR BETWEEN RESIDENCE  
CORRESPONDENCE, AND EXTENSION CLASS  
FOR GROUP C

| Group C                            | Correlation | Probable error |
|------------------------------------|-------------|----------------|
| Residence and correspondence       | .661        | .0307          |
| Residence and extension class      | .532        | .0395          |
| Correspondence and extension class | .685        | .0510          |

The reader will note that correlations between residence and correspondence grade-point averages and between correspondence and extension class grade-point averages are very similar. It will also be noted that the coefficient of correlation between the grade-point averages of residence and extension class is slightly lower than the other two but still shows marked relationship. According to these results a group of similar students receiving average marks by one method of instruction would very likely receive average marks in either of the other two methods presented in this study.

The coefficients of correlation (see Appendix B) between the grade-point averages for the three methods of instruction are presented in Table VIII.

TABLE VIII  
CORRELATION AND PROBABLE ERROR BETWEEN RESISTANCE  
CORRESPONDENCE AND EXTENSION CLASS  
FOR GROUP C

| Group C                            | Correlation | Probable Error |
|------------------------------------|-------------|----------------|
| Resistance and correspondence      | .851        | .0307          |
| Resistance and extension class     | .832        | .0312          |
| Correspondence and extension class | .687        | .0370          |

The reader will note that correlations between resistance and correspondence grade-point averages and between correspondence and extension class grade-point averages are very similar. It will also be noted that the coefficients of correlation between the grade-point averages of resistance and extension class is slightly lower than the other two but still shows marked relationship. According to these results a group of similar students receiving average marks by one method of instruction would very likely receive average marks in either of the other two methods presented in this study.

In order to substantiate the comparisons in Group C critical ratios were computed. The critical ratios for all undergraduates, undergraduate men, and undergraduate women were summarized in Table IX.

TABLE IX  
CRITICAL RATIOS FOR GROUP C

| Critical ratio of the difference between two means for Group C | Residence and  |                 |
|--|----------------|-----------------|
|  | correspondence | extension class |
| All undergraduates   | 3.2            | 7.2             |
| Undergraduate men  | .13            | 1.8             |
| Undergraduate women  | 2.2            | 7.5             |

The critical ratio is computed to be 3.2 for the difference between the means of residence and correspondence for all undergraduates. This is not large enough to insure significance but the probability is that ninety-eight times out of one hundred the difference is not due to chance of the sampling.

The undergraduate men have the lowest critical ratios of any group. The critical ratio computed for the difference between the means of residence and correspond-

THE UNIVERSITY OF CHICAGO

PHYSICS DEPARTMENT

TO THE FACULTY OF THE PHYSICS DEPARTMENT  
OF THE UNIVERSITY OF CHICAGO  
I have the honor to acknowledge the receipt of your letter of the 15th inst. regarding the proposed appointment of a new member to the faculty of the Physics Department. I am pleased to hear that you are considering the name of Mr. [Name] for this position. I have known Mr. [Name] for some time and believe that he is well qualified for the position. I am sure that his appointment would be a great benefit to the Department and to the University.

I am sure that his appointment would be a great benefit to the Department and to the University. I am sure that his appointment would be a great benefit to the Department and to the University. I am sure that his appointment would be a great benefit to the Department and to the University.

I am sure that his appointment would be a great benefit to the Department and to the University. I am sure that his appointment would be a great benefit to the Department and to the University. I am sure that his appointment would be a great benefit to the Department and to the University.

I am sure that his appointment would be a great benefit to the Department and to the University. I am sure that his appointment would be a great benefit to the Department and to the University. I am sure that his appointment would be a great benefit to the Department and to the University.

I am sure that his appointment would be a great benefit to the Department and to the University. I am sure that his appointment would be a great benefit to the Department and to the University. I am sure that his appointment would be a great benefit to the Department and to the University.

I am sure that his appointment would be a great benefit to the Department and to the University. I am sure that his appointment would be a great benefit to the Department and to the University. I am sure that his appointment would be a great benefit to the Department and to the University.

dence in this case is .13. The chances are 53.5 out of one hundred that the computed difference is not due to inadequate sampling. In other words there is an equal chance that additional sampling would not create a change. The other critical ratio for undergraduate men is 1.8. In this case, eighty-nine times out of one hundred the computed difference would not be due to chance.

The critical ratio for undergraduate women is 2.2 for the difference between the means of residence and correspondence. The element of chance in this case is ninety-three times out of one hundred the sampling would be valid.

The two remaining critical ratios for all undergraduates and undergraduate women are 7.2 and 7.5 respectively. Here again the critical ratios of such magnitude indicate that the true difference between the residence and extension class means in both cases is significantly greater than zero and the computed difference is not due to chance of the sampling involved.

Summary for Group C. To summarize the discussion for Group C, it may be said that this study indicates:

1. Correspondence grade-point averages are generally higher than those in residence.
2. Extension class grade-point averages are generally higher than those in residence.

dened in this case is 1.5. The observed and 1.5 out of  
one hundred that the computed difference is not due to  
independent sampling. In other words there is an equal  
chance that additional sampling would not reduce a  
change. The other critical ratio for undergraduate was  
1.8. In this case, eighty-five percent of one hun-  
dred the computed difference would not be due to chance.  
The critical ratio for undergraduate was 1.5  
for the difference between the means of residence and  
correspondence. The amount of change in this case is  
ninety-three times out of one hundred the sampling would  
be valid.

The two remaining critical ratios for all under-  
graduate and undergraduate were 1.5 and 1.5 re-  
spectively. Here again the critical ratios of each sig-  
nitude indicate that the true difference between the  
residence and extension class means in both cases is  
significantly greater than zero and the computed differ-  
ence is not due to chance of the sampling involved.

- SUMMARY FOR GROUP B.** To summarize the discussion  
for Group C, it may be said that this study indicates:
1. Correspondence grade-point averages are sig-  
nificantly higher than those in residence.
  2. Extension class grade-point averages are sig-  
nificantly higher than those in residence.

3. Extension class grade-point averages are generally higher than those in correspondence.

4. Grade-point averages for women are generally higher than grade-point averages for men.

## CHAPTER IV

### CONCLUSIONS AND RECOMMENDATIONS

#### I. CONCLUSIONS

Marks earned through residence work at the University of New Mexico are considered standards to which marks earned by extension study are compared either favorably or unfavorably. The important conclusion derived from this study is that extension work, including both correspondence study and extension classes, compares favorably with residence instruction at this University. This conclusion is substantiated by the following findings:

1. In every case, correspondence grade-point averages were higher than residence grade-point averages.
2. In every case, extension class grade-point averages were higher than residence grade-point averages.
3. The grade-point averages of all students for extension class work were higher than those for all students enrolled in correspondence study.
4. Coefficients of correlation computed in each case indicated that another like group would earn similar marks in residence, correspondence, and extension class.

Common to the thinking of college instructors concerning the work of extension students, is the following

CHAPTER IV

CONCLUSIONS AND RECOMMENDATIONS

I. CONCLUSIONS

This study through residence work at the University of New Mexico was conducted in accordance with the standards of the American Psychological Association and the standards of the American Educational Research Association. The important conclusions derived from this study are that extension work, including both correspondence and study and extension classes, compares favorably with residence instruction at this University. This conclusion is substantiated by the following findings:

1. In every case, correspondence students averaged higher than residence students on the average.
  2. In every case, extension class work points averaged higher than residence class work averages.
  3. The grade-point averages of all students for extension class work were higher than those for all students enrolled in correspondence work.
  4. Graduates of extension classes were more likely to be employed than graduates of residence classes.
- Based on the findings of this study, the following are the work of extension students, in the following

question: "Is the instruction given in extension courses as adequate as instruction in residence?" Three basic assumptions are implied by this question: (1) extension students are less capable; (2) extension instructors are more lenient because (a) the extension student is less capable or (b) the extension student is working under a handicap, being pressed both for finances and time and (3) because of these, extension work is inferior.

The validity of the assumptions just presented is clouded by many conflicting possibilities. Extension students may be overburdened with regular employment and consequently be unable to do good work. This may account for a sizeable number of concentrations of poor or mediocre extension grades. On the other hand, the working extension student may be motivated so highly that he is a very capable student. This fact may account for a relatively large number or heavy concentration of definitely superior extension grades. There is evidence that correspondence students who drop courses do so because they cannot fulfill work requirements. This would indicate that a selection process takes place, resulting in a high caliber of correspondence students.

One can only consider subjectively various possible aspects of the case. No study has yet taken into account total population in either residence, correspondence, or

...the ...

extension class work. The educational standards of the institutions themselves are different. Another fact is the possibility of application by the student, to his job or profession, of the material presented through instruction. The extension student is usually so situated that immediate use can be made of acquired learnings. His office or school room is his laboratory.

One can discuss objectively studies which have been presented concerning the subject. Investigators of the relationships of various types of college study have found: (1) that extension students are typically capable of doing satisfactory residence work<sup>1</sup>; (2) that students who have done both residence and extension work more often rate extension teaching as superior or equal to residence teaching than as inferior<sup>2</sup>; (3) that students who have had both residence and extension class study, or residence and correspondence study, make higher grades in residence than students with residence study alone<sup>3</sup>; and (4) when the results of performance of

<sup>2</sup> Marberry, op. cit., p. 56.

<sup>3</sup> Zeigel, op. cit., p. 225.

students on the Minnesota College Aptitude Test was compared with the results of the Minnesota Reading Test it was found that extension course students had slightly less ability than juniors and seniors in the Aptitude Test and slightly higher ability than juniors and seniors in the Reading Test.<sup>4</sup>

The data which have been presented neither support nor definitely refute the validity of any of the aforementioned assumptions. They do indicate clearly the relationships which have been discussed, but they do not support conclusions with respect to causes or effects.

The conclusion indicated by these considerations seems to be that one is not justified in making any of these assumptions. In fact, such evidence as does exist, seems to indicate a lack of any significant difference in quality between various methods of instruction. It is probable that no real conclusions about relative merit of various types of instruction or student work can be reached until exhaustive studies of the methods, content, and actual instruction in these courses have been completed.

## II. RECOMMENDATIONS

The extension service of the University of New Mexico offers many and varied kinds of courses to all kinds of people throughout the land. Extension students differ from residence students in that they are usually already employed. They are usually older and have formed their own opinions which are a reflection of their own economic and social positions. On the professional level increased preparation and technical training is required. Newer methods and ideas are developing in business and professions continually. Changing conditions in the industrial world cause changes in present positions and create new jobs. Employed people would do well to keep pace. There is an inherent desire for knowledge in almost every individual. Those who have the time, the desire, and the discipline necessary to carry on extension work want outlets for their ambitions. Well coordinated extension offerings give such people the chance to expand.

In view of this study and these considerations it can be said that there is need for much more study to develop a scientific method of evaluating extension work before adequate comparisons can be made to residence work.

The economic growth of the United States is an  
historic effort and varied kinds of business  
kinds of people throughout the United States  
differ from business structure in that they are usually  
already existing. They are usually older and have  
their own capital which are a reflection of their own  
economic and social position and the relationship  
increased productivity and the fact that it is possible  
to have a more and more and more and more and more  
productive productivity. The productivity of the  
industrial world which showed in the 19th century  
create new jobs. The productivity of the 20th  
century is an effort to create a productivity of the  
most every industrial. The productivity of the 21st  
century and the industrial world is to create a world  
work and create for their productivity. The productivity  
extension of the productivity of the world is to  
create.  
In the world and the world and the world  
can be said that the world and the world and the world  
develop a scientific world of productivity and the world  
before the world and the world and the world  
work.

Future studies on this topic should include opinions of instructors actually engaged in conducting extension classes or grading correspondence study. Their opinion as to hours spent on a particular lesson by the student, interest of the student in the course, application made of work presented in class, and capabilities of the student as viewed by the instructor, would present additional information of considerable value. On the other hand, opinions of the students enrolled in either extension class or correspondence courses concerning likes and dislikes, information received, and instructor presentation would aid materially. Such studies should include the ultimate aims of extension work and the content of the courses offered as compared to a corresponding residence class.

Considerable information could be obtained for the University of New Mexico by establishing a plan of investigation similar to that of Crump<sup>5</sup> in Oklahoma. Courses which are given by the three methods of instruction should be used. Groups of students who are enrolled in either residence, correspondence, or extension class could be equated, based upon the results of standardized tests. The success of such a study would be

---

<sup>5</sup> Crump, op. cit., pp. 46-67.

Factors studied on this topic should include the  
 role of instructor activity in teaching ex-  
 tension classes or evening correspondence study. Their  
 opinion as to how much of a teacher's class is the  
 student, interest of the student in the course, quality  
 of the work presented in class and capabilities  
 of the student as viewed by the instructor, would present  
 additional information of considerable value. On the  
 other hand, opinions of the students enrolled in either  
 extension class or correspondence courses concerning  
 their and their, instructor received, and instructor  
 presented would also be valuable. Such studies should  
 include the extent to which extension work and the con-  
 tent of the course offered is regarded as a satisfactory  
 for extension class.

Considerable information could be obtained for the  
 University of New Mexico by establishing a plan of in-  
 vestigation similar to that of *University of Michigan*.  
 Courses which are given by the evening method of in-  
 struction should be used. Opinions of students who are en-  
 rolled in either extension, correspondence or extension  
 class could be secured, first from the students of each  
 enrolled class. The interest of each study would be

University of New Mexico, School of Education

based upon full cooperation of instructors conducting the courses. From such studies valuable means of comparison between the three methods of instruction would be forthcoming.

REVIEWS

based upon full possession of the facts...  
course. From such study a definite course of instruction  
between the three subjects of instruction...  
order.
