## ABSTRACT

*A high-quality nanolayer graphene (NLG) coated hollow core fiber (HCF) platform has been demonstrated for accurate monitoring of refractive index (RI) changes so far mainly operate in liquids but not in air. The NLG with high index is deposited on the outer surface of the HCF, and an enhanced anti-resonant reflecting guidance is formed, which induces sharp periodic lossy dips in the transmission spectrum. A cute experiment conducted interrogating the transmission intensity of the lossy dip demonstrates a high resolution of  $2.73 \times 10^{-6}$  RIU and a sensitivity of -365.9 dB/RIU, which is two or three times higher than that of intensity-modulated RI sensors reported previously. We believe that this configuration opens research directions for highly sensitive sensing in researches of chemistry, medicine, and biology.*

**Keywords:** hollow core fiber, graphene, refractive index sensing, air

## 1. INTRODUCTION

Fiber-optic refractive index (RI) sensors with advantages of high sensitivity, low cost and compact size, have been employed as gaseous RI measurement. In recent years, surface plasma resonance RI sensors [1], grating-based RI sensors [2-4], and interferometric RI sensors [5-8], have attracted considerable interest. Graphene has attracted a great deal of attention on its fundamental physics and electronic properties due to its unique optical properties, e.g. self-polarization effect, large optical absorption, and relative high nonlinearity [9]. Therefore, many novel graphene based optical sensors have been presented through the combination of graphene and optical fiber, such as reduced graphene oxide based fiber-optic humidity sensor [10], graphene-based interferometer for chemical gas sensing [11], and graphene-coated microfiber for high-sensitivity gas sensing [12].

In this paper, we proposed and experimentally demonstrated a high-quality nanolayer graphene (NLG) coated a HCF based on the anti-resonant reflecting optical waveguide (ARROW), which could be used to measure simultaneously surrounding temperature and the RI of air. A cute experiment conducted interrogating the

transmission intensity of the lossy dip demonstrates a high resolution of  $2.73 \times 10^{-6}$  refractive index unit (RIU) and a sensitivity of -365.9 dB/RIU, which is two or three times higher than that of intensity-modulated RI sensors reported previously.

## 2. EXPERIMENT RESULTS

The schematic construction of the hollow core fiber (HCF) without coating graphene is shown in Fig. 1, which mainly consists of a hollow core (Polymicro Technologies, TSP025150) with an inner diameter of 20  $\mu\text{m}$  and a ring-cladding with a thickness of 53  $\mu\text{m}$ , the optical image for the cross section of which is illustrated in the inset. Then the graphene was coated on the outer surface of HCF by using Plasma Enhanced Chemical Vapor Deposition (PECVD).

Fig.1 The schematic construction of the HCF without coating graphene.

Prior to the NLG coated the HCF, the transmission spectra are not particularly uniform but appear to include other periodic components. We are inclined to explain that the existed NLG contributes to exciting the dominating anti-resonant reflecting mechanism while suppressing the other higher order anti-resonant reflecting effects. On the other hand, the NLG fabricated by PECVD possesses unique properties compared the reduced graphene oxide provided in this reference [10]. More interesting, the spectra seem to more uniform with more layers of graphene.

The gas pressure responses of the proposed sensors were tested by means of fixing it into a pressure chamber, where a commercial gas pressure generator (ZC-YFT-02Q) with a stability of  $\pm 0.2$  kPa and a high precision digital pressure meter were employed to regulate the pressure in the chamber. The applied gas pressure in the chamber was increased from 0.1 MPa to 1.8 MPa at room temperature, and the pressure was maintained for 5 min at each step. When the pressure increased from 0.1 MPa to 1.8 MPa, the ambient air RI changed from approximately 1.00026 to 1.00461. Fig. 3 displays the corresponding evolutions of the transmission spectra and amplitude change as a function of the surrounding refractive index. A linear regression of the raw data yields a sensitivity of 369.5 dB/RIU, which is two or three times larger than those (27 dB/RIU [13], 94.58 dB/RIU [14], and -110 dB/RIU [15]) of the intensity-modulated RI sensors reported previously.

### 3. CONCLUSION

A novel and compact NLG coated HCF sensor was demonstrated by means of splicing a section of HCF to SMFs. The HCF length was chosen as 3 mm in order to achieve a large fringe contrast of up to 15 dB. Such a sensor based on intensity modulation exhibits a high sensitivity of at the -365.9 dB/RIU at the refractive index of 1, which is two or three times higher than that of other intensity-modulated RI sensors reported previously. Our RI sensor also exhibits the advantages of compact size (3 mm), simple structure, easy fabrication, and good repeatability. However, a complex and large spectrum analyzer has to be employed to measure the change of the dip intensity in our current experiments, which is disadvantageous to RI measurements. So in the practical sensing applications, a simple demodulation device should be developed to measure the intensity at the dip wavelength.
