ABSTRACT

Despite the existence of two old, but well known, publications that cite Portuguese localities for the Sialidae (McLachlan, 1880; Navás, 1908), all more recent faunal works fail to report this family from Portugal (e.g., Monserrat, 1986; Aspöck *et al.*, 2001; Aspöck & Aspöck, 2011). We have recently reported Sialidae as a new taxon from Portugal (Badano *et al.*, 2011), but Megaloptera turn out to be relatively well known to aquatic biologists in Portugal (Teixeira *et al.*, 2009).

Here, a survey of the distribution of Sialidae in continental Portugal is presented within the framework of a collaboration with the Portuguese biodiversity project NaturData (<http://naturdata.com/>).

RESUMO

Apesar de duas publicações antigas bem conhecidas citarem localidades em Portugal com presença de Sialidae (McLachlan, 1880; Navas, 1908), várias referências recentes contudo não relatam esta família (e.g., Monserrat, 1986; Aspöck *et al.*, 2001; Aspöck & Aspöck, 2011). No entanto, mais recentemente, esta família foi reportada para Portugal (Badano *et al.*, 2011), sendo a ordem Megaloptera bem conhecida pelos limnólogos portugueses (Teixeira *et al.*, 2009).

No quadro de uma colaboração com o projecto NaturData (<http://naturdata.com/>) é apresentado um estudo de distribuição de Sialidae em Portugal Continental.

INTRODUCTION

The family Sialidae Leach in Brewster 1815 has a world wide distribution occurring in Europe, North and South America, Asia, eastern Australia, and Palearctic Africa, and about 80 living species. Ten species, all in the genus *Sialis* Latreille 1802, occur in Europe (Aspöck & Aspöck, 2011), and four of these (*Sialis gonzalezi* (Vhsivkova, 1985); *S. fuliginosa* (Pictet, 1836); *S. lutaria* (Linnaeus, 1758), and *S. nigripes* (Pictet 1865)) have been

recorded from the Iberian Peninsula (Monserrat, 1986). No known recent works prior to Badano *et al.* (2011) appear to report *Sialis* species from continental Portugal. There are, however, three older publications that do record sialid species in Portugal (McLachlan, 1880; Navás, 1908, 1915). McLachlan (1880; cfr. pag. 106) reported (with some doubts...) *Sialis lutaria* from two localities (Figure 1), one in central and a second in northern Portugal. Navás (1908; cfr. pag. 34) cited *Sialis fuliginosa* from the Portuguese locality of São Fiel (near

Castelo Branco) as San Fiel in a list of Spanish localities (Figure 2); seven years later, Navás (1915; cfr. pag. 202) ascribed the same specimen to the new described taxon *Sialis fumosa* Navás, 1915, a *nomen dubium* (Oswald, 2007) likely a synonym of *Sialis fuliginosa*. Older species-level identifications of *Sialis*, such as those of McLachlan and Navás, are generally regarded as unreliable, because the venational and general morphological traits used in such works are now known to be insufficient to accurately separate the modern concepts of species in the genus, which are based primarily on male terminalia (Elliott, 1996). A recent collecting trip to northern and central Portugal yielded two adult specimens of *Sialis fuliginosa* near Serra da Estrela National Park, allowing confirmation of the presence of that species in Portugal (Badano

et al., 2011), a century after Navás' report. An additional specimen of *Sialis fuliginosa* was collected in June of 2011 in the Peneda-Gerês National Park (northern Portugal; Oswald pers. com.) during the 'long excursion' following the XI International Symposium on Neuropterology (11ISN). A considerable volume of additional Portuguese sialid data has become available through the Aquariport Project (Teixeira *et al.*, 2009) and through collaborations with the staff of Portuguese biodiversity project NaturData (<http://naturdata.com/>).

Faunal data

The primary aim of this study is to document and summarize all known faunal information concerning the genus *Sialis* in continental Portugal.

PLANIPENNIA.

SIALIDÆ.

Sialis lutaria, L.—One ♀, Cintra, 27th April, in the ordinary condition. There is also one ♂ from near Salamonde, 2003 feet, 30th June, that I refer here with some hesitation. It has the dark coloration of *S. fuliginosa* (and even intensified), yet the anal structure is that of *lutaria*, only that the terminal ventral lobe appears slightly shorter, and slightly less obtuse at its apex. It is distinctly not the Spanish *S. nigripes*, Ed. Pict. (which I cannot separate from *fuliginosa*, *vide ante*, p. 62). At present, therefore, in the absence of sufficient materials, I am forced to consider it *lutaria*, with possibly slight modification in the anal parts, and with the coloration of *fuliginosa*.

FIGURE 1. *Sialis lutaria* in McLachlan's "Notes on the entomology of Portugal".

venación gruesa, parda ó negra. Antenas filiformes. Patas normales, con el cuarto artejo de los tarsos ensanchado en dos lóbulos.

1. *Sialis lutaria* L. — Costal amarillenta en la base. Membrana del ala casi hialina, teñida ligeramente de pardo en toda su extensión. Vértez con dos estrías amarillas longitudinales en el centro. Enverg. 25-30 mm.

Panticosa I (Vázquez), Miracle I (P. Marçet), Zaragoza I, Burgos I (Fernández Duro).

2. *Sialis fuliginosa* Pict. (*nigripes* E. Pict.). — Membrana del ala anterior visiblemente más obscura en la base (Lám. III, fig. 6); vena costal igualmente parda en toda su extensión. Callos en el vértez y occipucio apenas teñidos de amarillento. Enverg. 26-32 mm.

San Ildefonso (Ed. Pictet), Escorial I (Lauffer, Dusmet), Córdoba (Hern. Pacheco), San Fiel I (Silvano), Cangas de Tineo I (Flórez).

FIGURE 2. *Sialis fuliginosa* in Navás' "Neuropteros de España y Portugal".

These data are summarized in Table 1, based on a compilation prepared for a presentation at the 11ISN (Letardi, 2011).

To date, *Sialis fuliginosa* is the only sialid species that has been definitely confirmed from continental Portugal. However, many confirmed *Sialis* specimens that are not identifiable to species have been collected in Portuguese localities that exhibit micro-environmental conditions that are consistent with those where *Sialis lutaria* and *S. nigripes* might be expected. As the latter two species are known to be widely distributed in the Iberian Peninsula (Monserrat, 1986), it is likely that one or both of these additional species occur

in Portugal as well. In any case, recent documentation of collection localities for *Sialis* in Portugal (Figure 3), primarily larval specimens (>400) collected in association with the Aquariport project, clearly demonstrate that the Portuguese distribution of *Sialis* has been severely underestimated previously, and that the genus is broadly present in appropriate microhabitats throughout the north, center, and south of Portugal.

ACKNOWLEDGEMENTS

We thank Rui Andrade (Naturdata, Portugal), Armando Caldas (Porto, Portugal), José Manuel Grosso-Silva
