Study of hydrogen bonding interactions and chemical reactivity analysis of nitrofurantoin–3-aminobenzoic acid cocrystal using quantum chemical and spectroscopic (IR, Raman, ^{13}C SS-NMR) approach

Anuradha Shukla^a, Eram Khan^a, Karnica Srivastava^a, Kirti Sinha^a, Poonam Tandon^{a*}, Venu R. Vangala^{b*}

The investigations of structural reactivity, molecular interactions and vibrational characterization of pharmaceutical drug are helpful to understand their behaviour. The aim of this study is to determine the molecular, electronic and chemical properties of an antibiotic drug, nitrofurantoin (NF), after cocrystallisation with 3-aminobenzoic acid (3ABA) and to understand as to how those changes lead to variation of properties in the cocrystal, NF-3ABA. NF-3ABA formation is explained by the stabilization *via* hydrogen-bond network between NF and 3ABA molecules. It is thoroughly characterized by IR, Raman and CP-MAS solid-state ^{13}C NMR techniques, along with quantum chemical calculations. The indications of IR, Raman, and ^{13}C NMR showed that imide N—H23 and C12=O of NF interacts with the acid C=O and —OH groups in 3ABA, respectively. Therefore IR, Raman, and ^{13}C NMR spectra verified the formation of N—H···O and O—H···O hydrogen bonds. To study hydrogen bonding interactions theoretically in NF-3ABA, two functionals; B3LYP and wB97X-D have been used. A comparison is made between the results obtained by B3LYP and those predicted at wB97X-D level. It is found that wB97X-D is best applied density functional theory (DFT) functional to describe the hydrogen bonding interactions. The strength and nature of hydrogen bonding in NF-3ABA have been analysed by quantum theory of atoms in molecules (QTAIM) and natural bond orbital (NBO) analysis. To validate the results obtained by QTAIM theory and to study the long-range forces, such as van der Waals interactions, steric effects in NF-3ABA, the reduced density gradient (RDG) and the isosurface have been plotted using Multiwfns software. QTAIM and isosurface analysis suggested that the hydrogen bonding interactions present in the NF-3ABA are moderate in nature. The calculated HOMO–LUMO energy gap shows that the NF-3ABA is more active than NF and 3ABA. Chemical reactivity descriptors are calculated to understand the various aspects of pharmacological sciences. Chemical reactivity parameters show that the NF-3ABA is more softer and chemically more reactive than NF. The results suggest that cocrystals can be a feasible alternative for positively changing the targeted physicochemical properties of an active pharmaceutical ingredient (API).

I. Introduction

APIs are materials that are most efficiently developed and expressed as solid dosage forms.¹ A significant number of APIs pose poor physical properties during formulation and dosage form development. Cocrystallization is an emerging approach for positively modifying API properties. Pharmaceutical cocrystals are molecular adducts of definite stoichiometry where one component is an API and the other is a counter molecule (co-former) and both components are solids that are crystalline single phase materials.²

Cocrystals are held together by non-covalent interactions such as hydrogen bonding, π – π -stacking and van der Waal forces within the same crystal lattice.^{3,4} Pharmaceutical cocrystals raise important intellectual and physical property issues in the context of drug advancement and delivery.⁵ Cocrystals can lead to improvements in physical and chemical stability as well as in mechanical properties by diversifying the number of crystal forms that exist for an API. Cocrystals of an API may show enhanced solubility, bioavailability, stability, and dissolution rates compared to that of pure material.⁶

NF is an antibacterial agent, which is used to treat bacterial infections of the urinary tract (bladder and kidneys). This drug works by interrupting with the bacterial metabolism of carbohydrate, disrupting the formation of the bacterial cell wall and interfering with the production of vital nutrients. This drug has poor water solubility⁷ and its dissolution in water is, therefore, the rate-limiting step in its absorption from the gastrointestinal tract.⁸ NF presents some bioavailability problems which are strictly related to the crystal size and to the two anhydrate and two monohydrate

PAPER

crystalline forms.^{9,10} It has been reported that the dissolution rate and bioavailability of NF in commercial tablets decreased upon storage at different relative humidity and elevated temperature.¹¹ Otsuka and co-workers suggested that the physicochemical stability of NF could be one of the important factors for controlling the bioavailability of commercial preparations.¹²

Research in cocrystals has seen dramatic development in recent years, mostly driven by their pharmaceutical applications where properties such as hardness or tabletting, solubility are of paramount importance.^{13,14} Recent advancements have indicated a great potential of cocrystals for improving the physicochemical properties of APIs.^{15,16} In the recent years, there has been growing interest in the application of *ab initio* calculations to pharmaceutical cocrystals.¹⁷⁻¹⁹ Vibrational spectroscopic investigations combined with quantum chemical calculations have been utilized as one of the most effective tools for providing information about structure, composition, conformation and intra/intermolecular interactions and vibrational analysis of cocrystals.^{20,21} Solid state NMR (SS-NMR) spectroscopy has proved to be a remarkable tool to explain the molecular structure and conformation at the molecular level.²² The isotropic chemical shifts provide the useful information regarding the geometry and reactivity of the atoms within the molecule. The aim of this study is to determine the molecular, electronic and chemical properties of NF after cocrystallisation with 3-aminoarboxylic acid (3ABA) and to understand as to how those changes lead to variation of properties in the cocrystal, NF-3ABA.

In the present study, we have investigated the performance of density functionals, one of which is "standard" functional not including dispersion (B3LYP) while the other has been constructed to account for dispersion (wB97X-D), in reproducing molecular structures. The main differences between B3LYP and wB97X-D are the addition of a semi empirical dispersion term that accounts for the weaker London forces. In this contribution, we have performed detailed computational and vibrational analysis of NF-3ABA and its constituents, NF and 3ABA employing quantum chemical methods. The solid-state properties of NF-3ABA are mainly governed by the strong intermolecular hydrogen bond forces. DFT has been comprehensively used in the literature to address this type of interactions.^{23,24} The effect of intermolecular hydrogen bonding on the infrared (IR), Raman and solid-state NMR spectra of NF-3ABA has been examined by DFT calculations using both B3LYP and wB97X-D functionals with cc-pVTZ basis set. The calculated vibrational spectra are analysed based on the potential energy distribution (PED) analysis. In general, the formation of H-bond can be estimated by the structural parameters (bond length and bond angle), and the strength of the H-bond can also be determined by enlarging or shortening of the H-bond length. However, in many cases, the H-bond interactions are too complex to learn just by the structural parameters. Due to this, the quantum theory of atoms in molecules (QTAIM) and natural bond orbital (NBO) analysis have been used for the analysis of the nature and strength of H-bond.²⁵ The highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO) band gap of NF-3ABA and its constituents have been compared for predicting their stability. Chemical activity has been measured by reactivity descriptors (global and local) and molecular electrostatic potential surface (MEP) for rationalisation and interpretation of diverse aspects of

chemical bonding. This study aimed to conceptualize the hydrogen bond formation and its effect on vibrational spectra and natural bond orbitals in NF-3ABA.

II. Experimental details

Bio-Rad, FTS 3000MX FT IR spectrometer was used for transmission infrared spectra of the NF-3ABA, NF and 3ABA. The spectra were collected for 64 scans at 4 cm⁻¹ resolution. Typically, ~25 mg of the sample was ground with KBr in an agate mortar and pressed with a steel die into a pellet.

FT-Raman spectrum of the NF-3ABA was recorded on a Bruker IFS 55 EQUINOX with Raman attachment. This instrument uses a 1064 nm Nd-YAG laser line of power 500 mW as the excitation line for recording the Raman spectra in the region 20–3400 cm⁻¹. The spectra were collected for 512 scans at 4 cm⁻¹ resolution.

The dispersive Raman microscope used in this study was a JYHoriba LabRAM HR equipped with a confocal microscope, liquid-nitrogen-cooled charge coupled device (CCD) and a multichannel detector (256 pixels × 1024 pixels). The NIR 784.8 nm argon ion laser was selected to excite the Raman scattering. The Raman shift range collected was in the range of 100–1700 cm⁻¹ with spectral resolution 1.7–2 cm⁻¹.

Cross-polarization Magic Angle Spinning (CP-MAS) solid state NMR spectra were acquired using a Bruker Avance III HD 400 MHz spectrometer fitted with a 4 mm HX-MAS BB/1H probe head. Samples were packed without further manipulation into 4 mm ceramic spinners. 116 scans were acquired using cross polarization with TOSS spinning sideband suppression. A 1 ms contact time, 120 s recycle delay and a spin rate of 10 kHz was used. Spectral referencing was with respect to an external sample of neat tetramethylsilane (carried out by setting the high-frequency signal from adamantane to 38.5 ppm). All solid-state NMR spectra were obtained at the EPSRC UK National Solid State NMR Service at Durham.

III. Computational details

The electronic structure and optimized geometry of NF-3ABA and its constituents were computed by the DFT method²⁶ using the Gaussian 09 program²⁷ package employing cc-pVTZ, correlation consistent polarized valence triple- ζ , basis sets^{28,29} and Becke's three parameter (local, nonlocal, Hartree-Fock) hybrid exchange functionals with Lee-Yang-Parr correlation functional (B3LYP)^{30,31,32} and wB97X-D functional³³ which uses a version of Grimme's D2 dispersion model. The cc-pVTZ basis set was developed by Dunning and co-workers³⁴⁻³⁶ provide a convenient reference set of optimized Gaussian basis sets. A complete set of internal coordinates were defined using Pulay's recommendations³⁷ for normal mode analysis. The vibrational assignments of the normal modes were suggested based on the PED calculated using the program Gar2Ped.³⁸ Visualization and confirmation of calculated data were done by using the program GaussView.³⁹ ¹³C chemical shifts were calculated for NF-3ABA, NF and 3ABA with GIAO method. Topological properties at bond critical points (BCP) have been studied within the framework of the QTAIM using the AIM2000 package of programs.⁴⁰

IV. Theoretical background

Density functional theory (DFT) calculations yield Raman scattering amplitudes, which cannot be taken directly to be the Raman intensities. Raman scattering cross section, $\partial\sigma/\partial\Omega$, which is proportional to Raman intensity can be calculated from the Raman scattering amplitude and predicted wavenumbers for each normal mode using the relationship.⁴¹

$$\frac{\partial\sigma_j}{\partial\Omega} = \left(\frac{2^4\pi^4}{45}\right) \left(\frac{(v_0 - v_j)^4}{1 - \exp\left[\frac{-hcv_j}{kT}\right]}\right) \left(\frac{h}{8\pi^2cv_j}\right) S_j$$

S_j and v_j are the scattering activities and the predicted wavenumbers, respectively of the j^{th} normal mode, v_0 is the wavenumber of the Raman excitation line and h , c and k are universal constants.

Calculated NMR provide predictions of absolute chemical shift shielding tensors that need to be correlated to conventional σ (TMS) values for comparison with results from typical NMR experiments.⁴² First computed isotropic shielding constants(σ) were obtained for each nucleus and these were converted to a chemical shift (δ) value per formula is given below.

$$\delta_i = \sigma_{\text{TMS}} - \sigma_i$$

The reference substance was tetramethylsilane (TMS) which is most commonly used reference for ^{13}C spectra.

Mean absolute errors were calculated per formula, for estimating the effect of different functional on calculated NMR spectra:

$$\text{mae} = \frac{\sum_n |\delta_{\text{exp}} - \delta_{\text{cal}}|}{n}$$

where δ_{exp} and δ_{cal} represent experimental and calculated chemical shifts, respectively.

By DFT calculation, it is possible to define and clarify the concepts of chemical reactivity. Global DFT descriptors like the chemical potential (μ), hardness (η), softness (s), electronegativity (χ) and the electrophilicity index (ω) investigate the reactivity of the molecule, and this has been established effectively.^{43,44} Within the theoretical framework of DFT, global DFT descriptors were calculated as per formula:

$$\begin{aligned}\mu &= -\chi = \frac{1}{2}(E_{\text{HOMO}} + E_{\text{LUMO}}) \\ \eta &= \frac{1}{2}(E_{\text{LUMO}} - E_{\text{HOMO}}) \\ s &= \frac{1}{2\eta} \\ \omega &= \frac{\mu^2}{2\eta}\end{aligned}$$

This new reactivity index (ω) measures the stabilization in energy when the system acquires an additional electronic charge (ΔN) from the environment. The maximum electronic charge that the electrophile may accept from the surroundings (ΔN_{max}) may be defined as:

$$\Delta N_{\text{max}} = -\frac{\mu}{\eta}$$

The amount of charge transfer between the two molecules A and B could be expressed in terms of electrophilicity charge transfer (ECT)⁴⁵ and it is defined as the difference between ΔN_{max} values of interacting molecules. ECT is calculated using equation.

$$\text{ECT} = (\Delta N_{\text{max}})_A - (\Delta N_{\text{max}})_B$$

where

$$(\Delta N_{\text{max}})_A = \frac{\mu_A}{\eta_A} \text{ and } (\Delta N_{\text{max}})_B = \frac{\mu_B}{\eta_B}$$

Three kinds of fukui functions (FF) around each atomic site, namely, f_k^+ , f_k^- and f_k^\cdot can be used to describe the electrophilic, nucleophilic and radical reactivity, respectively, which are defined in a finite difference approximation.⁴⁶ According to Parr and Yang,⁴⁶ the higher FF values point to the more reactivity of the atom than others.

Molar refractivity (MR) is an important property used in quantitative structure property relationship. It is calculated by the Lorentz–Lorentz equation^{47,48} and is defined as:

$$\text{MR} = \left[\frac{n^2 - 1}{n^2 + 2} \right] \left(\frac{\text{MW}}{\rho} \right) = 1.333 \pi N \alpha,$$

while n is the refractive index; MW is the molecular weight; ρ is the density; (MW/ρ) is the molar volume; N is the Avogadro number; α is the polarizability of the molecular system.

In NBO analysis, the hyper conjugative interaction energy was deduced from the second-order perturbation approach⁴⁹

$$E^{(2)} = -q_i \left[\frac{(F_{ij})^2}{\epsilon_i - \epsilon_j} \right]$$

where, q_i is the population of donor orbital or donor orbital occupancy; ϵ_i , ϵ_j are orbital energies of donor and acceptor NBO orbitals, respectively; F_{ij} is the off-diagonal Fock or Kohn-Sham matrix element between i and j NBO orbitals.

Espinosa⁵⁰ proposed proportionality between hydrogen bond energy (E) and potential energy density (V_{BCP}) at H···O contact:

$$E_{\text{HB}} = \frac{1}{2} V_{\text{BCP}}$$

V. Results and discussion

1. Geometry optimization and energies

NF-3ABA (1:1) cocrystal crystallizes in the triclinic system in the space group $P\bar{1}$ with one molecule each of NF and 3ABA adopting planar conformation in the asymmetric unit.⁵¹ As far as the crystallographic structure of NF-3ABA is concerned, the imide of NF and acid of 3ABA form an O–H···O and N–H···O interactions as shown in the Fig 1. It was noted there is a C–H···O dimer is formed between the activated C–H and nitro group of furyl ring in NF. Next, the primary NH₂ of 3ABA is involved in bifurcated N–H···O and N–H···N interactions with the available O/N acceptors of NF. The solid-state packing is further supported by C–H···O interactions to complete a sheet structure.⁵¹ In present calculation, the planer configuration of NF-3ABA (1:1) has been adopted for calculating the different properties. Initial geometry optimization of NF-3ABA (1:1) was performed using the crystallographic data of cocrystal reported by one of the authors of current work.⁵¹ Initial geometry for NF (API), 3-ABA (co-former), and NF-3ABA (cocrystal) was minimized at the DFT level employing B3LYP/cc-pvTZ and wB97X-D/cc-pvTZ level of theory.

The ground state optimized structure of NF-3ABA, NF, and 3ABA using wB97X-D/cc-pvTZ are shown in Fig. 1 and in electronic supplementary information (ESI†, see Fig. S1 and Fig. S2). The optimized structural parameters (bond lengths, bond angles, and dihedral angles) of the NF and NF-3ABA cocrystal were also compared with the experimental results (See also Table S1, ESI†).⁵¹

PAPER

It may be seen that both the functional yield comparable geometries, which differ from the experimental geometry⁵¹ by not more than 0.02 Å in bond length except for the bonds having one of the atoms as hydrogen. A comparison of the bond angles shows that calculations can replicate the experimental data within 3.1° in bond angles and 5.4° in dihedral angles. The calculated bond length of N-H and C=O bonds of the hydantoin ring in pure NF was found to be 1.0076 Å and 1.2023 Å, respectively, whereas in NF-3ABA it was found to be 1.0297 and 1.2185 Å, respectively. The variations in the bond length of N-H and C=O bonds NF-3ABA are due to the presence of H-bonds between NF and 3ABA, which has resulted in the increment of bond lengths.

The ground state energy of the NF-3ABA was calculated using B3LYP/cc-pvTZ and wB97X-D/cc-pvTZ are -1380.17103 a.u. and -1379.70158 a.u., respectively. In the NF-3ABA, intermolecular hydrogen bonds were formed between NF and 3ABA. E_{int} can be computed using either supermolecular or perturbative approach. In this work, DFT methods (such as B3LYP, and wB97X-D) are used to obtain E_{int} within the framework of the supermolecular approach. According to former, the interaction energy of the analyzed NF-3ABA was computed as the difference between the calculated total energy of the NF-3ABA and the energies of the two isolated molecules i.e. NF and 3ABA. The total energy of NF and 3ABA was calculated using wB97X-D/cc-pvTZ (B3LYP/cc-pvTZ) is -903.48793 (-903.78559) a.u. and -476.19615 (-476.36336) a.u. respectively. Therefore, the interaction energy (E_{int}) of the NF-3ABA were calculated using wB97X-D/cc-pvTZ and B3LYP/cc-pvTZ as -17.85 kcal/mol and -15.76 kcal/mol, respectively. The interaction energies may be influenced by the basis set superposition error (BSSE), which is generally amended by the counterpoise (CP) method of Boys and Bernardi.⁵² The calculated E_{int} of NF-3ABA has been corrected for the basis set superposition error (BSSE) via the standard counterpoise method⁵² and found to be -16.76 kcal/mol and -14.51 kcal/mol using wB97X-D/cc-pvTZ and B3LYP/cc-pvTZ, respectively.

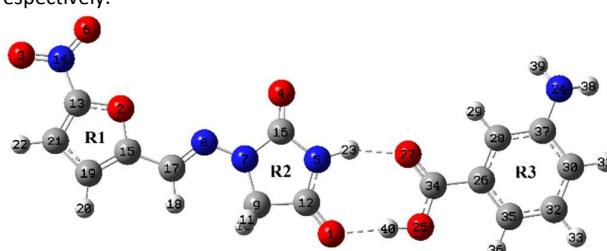

Fig. 1 Optimized structure for NF-3ABA using wB97X-D/cc-pvTZ method and the atom numbering scheme adopted in this study.

2. Vibrational spectra

Total number of atoms in NF-3ABA, NF and 3-ABA are 40, 23 and 17 and it gives 114, 63 and 45 (N-number of atoms) normal modes of vibrations respectively, all active in infrared and Raman spectra. The recorded and calculated vibrational wavenumbers at the wB97X-D/cc-pvTZ and B3LYP/cc-pvTZ for NF-3ABA and their probable assignments with PED are given in Table S2 and Table S3 (ESI†) respectively. The theoretical and experimental vibrational wavenumbers of NF (API) and 3ABA (co-former) calculated at wB97X-D/cc-pvTZ and B3LYP/cc-pvTZ methods and their

assignments using PED are given in Table S4 and S5 (ESI†) respectively. Here the mode with maximum contribution is accepted to be the most significant mode.

This is obvious that the frequencies calculated based on quantum mechanical force fields usually differ appreciably from observed frequencies. This difference between calculated and observed spectra can be attributed to several factors. Firstly, to the environment (gas and solid phase) and secondly due to neglect of anharmonicity effects present in a real system. Frequency calculations were performed in the limit of the harmonic approximation. Therefore, calculated wavenumbers are scaled down using the scaling factor 0.965⁵³ for B3LYP/cc-pvTZ and 0.956⁵⁴ for wB97X-D/cc-pvTZ to discard anharmonicity present in the real system. The comparison among calculated and observed FT-IR and FT-Raman spectra of NF-3ABA is shown graphically in Figs. 2 and 3, respectively. Comparison of experimental and calculated (scaled) IR and Raman spectra of NF and 3ABA are shown in Figs. S3–S6 (ESI†).

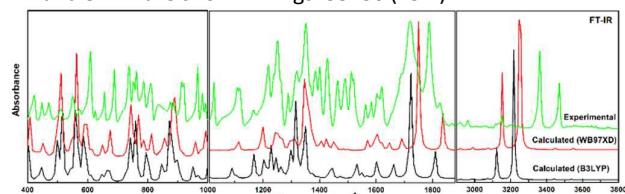

Fig. 2 Experimental and calculated (wB97XD and B3LYP) IR spectra of NF-3ABA.

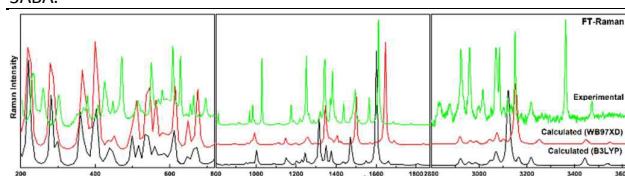

Fig. 3 Experimental and calculated (wB97XD and B3LYP) Raman spectra of NF-3ABA.

3. ^{13}C NMR chemical shift

In the present work, NMR chemical shifts for NF-3ABA, NF (API) and 3ABA (co-former) were computed with the B3LYP³⁰ and wB97X-D³³ functionals and the cc-pVTZ basis set²⁹ using GIAO method. The rationalisation behind the selection of these functional was to include the most frequently used hybrid functional (B3LYP) and one long range-corrected hybrid including dispersion corrections (wB97X-D). To compare the predicted values with experimental results, we also need to compute the absolute shielding value for the TMS, using the same model (level of theory, basis set and method of geometry optimization). To further examine the intermolecular interactions between nitrofurantoin and 3-aminobenzoic acid, the ^{13}C CP-MAS solid state NMR spectra of the NF-3ABA, NF and 3ABA were determined are shown in Fig. 4. The experimental and calculated ^{13}C NMR chemical shifts of NF-3ABA, NF and 3ABA are recorded in Table S6 (ESI†). The highest ^{13}C chemical shifts of C12 and C34 at 174.602 ppm and 171.077 ppm, which shows the bonding with the electron attracting species (here O and N) as shown in Fig 1 in the case of NF-3ABA cocrystal. A single peak is observed for the carbon atoms having same surroundings. The rest of the carbon atoms peaks of NF-3ABA are in the range of 47.950–150.811 ppm. The comparison between the spectra of NF and the NF-3ABA showed that the peak at position 168.9 ppm,

which was allotted to C11=O in NF, shifted to 174.602 ppm in the NF-3ABA. Thus, the environment of C11=O in NF had changed after cocrystal formation. This shift could be attributed to the change in the environment of the neighbouring -OH. Table S6 (ESI[†]) shows that calculated chemical shifts, which matches well with that of experimental values. The mean absolute errors for the same basis set with different functionals were calculated to identify the effect of different functional. The mean absolute errors for different functional are given in Table S7 (ESI[†]). Mean absolute error when considering same basis set with different functionals B3LYP and wb97X-D were 4.46 ppm and 3.87 ppm respectively for NF-3ABA and 3.29 ppm and 2.60 ppm respectively for NF. We found that wb97X-D functional was the best for calculating ¹³C chemical shifts (with GIAO approaches) in comparison to B3LYP functional.

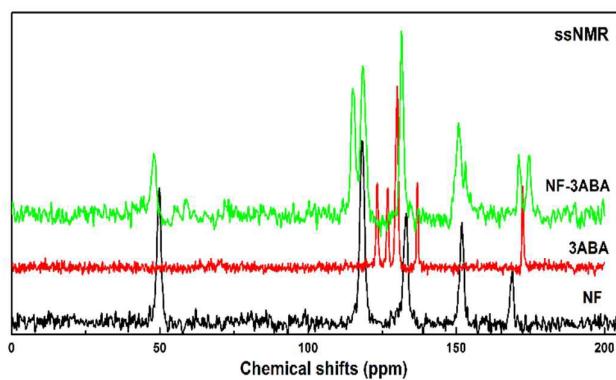

Fig. 4 Experimental ¹³C NMR spectrum of NF, 3ABA and NF-3ABA cocrystal.

Least square regressions were employed to determine the quality of the linear relationship; $y = mx + C$, where x is the calculated ¹³C NMR chemical shifts (δ in ppm), m is the slope, y is the experimental ¹³C NMR chemical shifts (δ in ppm) and C is the constant, between the experimental and the calculated chemical shifts. The linear relationship as well as the fit equation for data obtained with the GIAO/wB97X-D/cc-pVTZ method for NF-3ABA and NF is shown in Fig. S8 (ESI[†]). As illustrated in Fig. S8, the coefficients of determination values (R^2) for NF-3ABA and NF ¹³C NMR are equal to 0.9975 and 0.9964, respectively. This shows that there is a good agreement between experimental and calculated ¹³C NMR chemical shifts.

4. Natural bond orbital analysis (NBO)

NBO analysis is one of the efficient methods for studying the role of intermolecular and intramolecular orbital interaction and knowing about charge transfer and conjugative interactions in the complex. NBO offers quick understanding of the bonding in the molecules. NBO analysis is performed by considering all possible interactions between filled donor Lewis-type and empty acceptor Lewis-type NBOs and predicting their energetic significance by second-order perturbation theory. In the present work, taking the advantage of the second-order perturbation theory analysis, herein we report some of the electron donor and acceptor orbitals and the interaction stabilization energy. The intensity of the interaction between electron donors and electron acceptors, i.e. the propensity of donating more electrons from donors to acceptors depend on the $E^{(2)}$ value. NBO analysis has been performed on the title compound at the wb97X-D/cc-pVTZ and B3LYP/cc-pVTZ level to

explain the intra-molecular rehybridization and delocalization of electron density within the molecule. Table S8 and S9 (ESI[†]) summarizes the selected second-order perturbative estimates of "donor-acceptor" (bond-antibond) interactions in the NBO basis for the NF-3ABA, which shows π -conjugation/resonance due to π -electron delocalization in ring, primary and secondary hyper conjugative interactions. The calculated stabilization energy using B3LYP/cc-pVTZ are given in parenthesis. Here only those hyperconjugative interactions are discussed which are involve in the hydrogen bonding and show high stabilization energy.

The primary hyperconjugative interactions $n_2(O1) \rightarrow \sigma^*(N5-C12)/\sigma^*(C9-C12)$, $n_2(O2) \rightarrow \pi^*(C13-C21)/\pi^*(C15-C19)$, $n_2(O3) \rightarrow \sigma^*(O6-N14)/\sigma^*(C13-N14)$, $n_3(O3) \rightarrow \pi^*(O6-N14)$, $n_2(O4) \rightarrow \sigma^*(N5-C16)/\sigma^*(N7-C16)$, $n_2(O6) \rightarrow \sigma^*(O3-N14)/\sigma^*(C13-N14)$, $n_1(O25) \rightarrow \sigma^*(O27-C24)$, $n_2(O25) \rightarrow \pi^*(O27-C34)$, and $n_2(O27) \rightarrow \sigma^*(O25-C34)/\sigma^*(C26-C34)$ are stabilized the molecule to a greater extent ~ 157.41 kcal/mol. The other interactions $n_1(N5) \rightarrow \pi^*(O1-C12)/\pi^*(O4-C16)$, $n_1(N7) \rightarrow \pi^*(O4-C16)/\pi^*(N8-C17)$, $n_1(N8) \rightarrow \sigma^*(N7-C9)/\sigma^*(C17-H18)$ and $n_1(N24) \rightarrow \pi^*(C28-C37)$ are also stabilized the molecule with maximum energy ~ 239.34 (~ 73.47) kcal/mol.

The primary hyperconjugative interaction from unit (1) to unit (2) due to $n_1(O1)/n_2(O1) \rightarrow \sigma^*(O25-H40)$ stabilized the molecule up to ~ 17.88 (~ 14.19) kcal/mol and confirms the presence of interaction O25-H40...O1. Another intermolecular interaction from unit (2) to unit (1) due to $n_1(O27)/n_2(O27) \rightarrow \sigma^*(N5-H23)$ stabilized the molecule up to ~ 12.04 (~ 9.58) kcal/mol and confirms the presence of interaction N5-H23...O27.

5. QTAIM calculation: Topological parameters at bond critical points (BCP)

The quantum theory of atoms in molecules (QTAIM) theory provides a significant amount of information about the properties of any chemical bonds including hydrogen bonds. The theory of QTAIM well describes H-bonding and its concept. Bond critical point (BCP) is used in the identification of chemical bonds between atoms and interatomic interaction. The QTAIM method gives information about the ED region of a system and governs properties at BCPs. Geometrical and topological parameters are useful tools to characterise the strength and nature of the H-bond. Koch and Popelier⁵⁵ proposed a set of criteria for the existence of H-bond based on AIM theory. The criteria provide a basis to distinguish these interactions from van der Waals interactions and have been proved to be valid for standard and non-conventional H-bonds. According to Rozas et al.,⁵⁶ the interactions may be classified as follows: (i) for strong H-bonds ($\nabla^2\rho_{BCP} < 0$, $H_{BCP} < 0$ and covalent in nature, (ii) for medium H-bonds ($\nabla^2\rho_{BCP} > 0$, $H_{BCP} < 0$ and partially covalent in nature and (iii) for weak H-bonds ($\nabla^2\rho_{BCP} > 0$ and $H_{BCP} > 0$ and electrostatic in nature.

Molecular graph of the NF-3ABA using AIM program at wb97X-D/cc-pVTZ level is given in Fig. 5. Geometrical as well as topological parameters for bonds of interacting atoms in NF-3ABA are given in Table 1. Based on these parameters, O1...H40 and O27...H23 are moderate hydrogen bonds. The nature of these H-bonds is partially covalent due to ($\nabla^2\rho_{BCP} > 0$ and $H_{BCP} < 0$). The various types of interactions visualized in molecular graph are classified based on geometrical, topological and energetic parameters. In this article,

PAPER

the Bader's theory application has been used to estimate hydrogen bond energy (E). The energy of these H-bonds is calculated as $-11.60/-12.34$ and $-10.22/-10.79$ kcal/mol using B3LYP/wB97X-D functionals, respectively and their strengths are in the following order: O1···H40 > O27···H23. The results obtained by QTAIM theory is also validated with the help of the reduced density gradient (RDG) and the isosurface analysis using Multiwfn software⁵⁷ (ESI†).

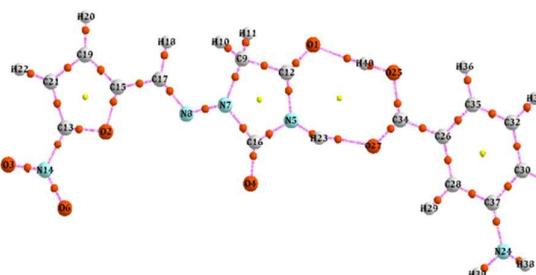

Fig. 5 Molecular graph of the NF-3ABA using AIM program at wB97X-D/cc-pvTZ method: bond critical points (small red spheres), ring critical points (small yellow sphere), and bond paths (pink lines).

Table 1 Geometrical parameters (bond length) and topological parameters for bonds of interacting atoms: electron density (ρ_{BCP}), Laplacian of electron density ($\nabla^2 \rho_{BCP}$), electron kinetic energy density (G_{BCP}), electron potential energy density (V_{BCP}), total electron energy density (H_{BCP}) at bond critical point (BCP) and estimated hydrogen bond energy (E_{HB}).

6. Frontier Molecular Orbitals (FMOs) analysis

The frontier molecular orbital plays a significant role in the electric and optical properties of the molecule.^{58,59} Highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) energies are very important parameters for quantum chemical calculations. HOMO energy characterizes the capability of electron giving and LUMO energy is related to the electron affinity. To calculate the reactivity of the molecule, the energies of HOMO, LUMO and HOMO–LUMO energy gaps are calculated using wB97X-D/cc-pvTZ and B3LYP/cc-pvTZ basis sets for the both NF and NF-3ABA.

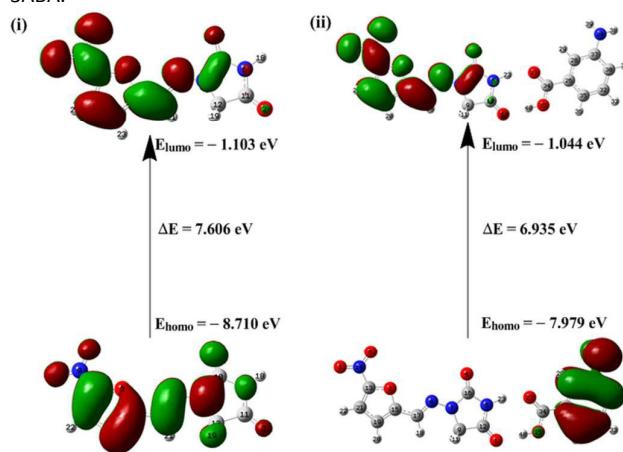

Fig. 6 HOMO-LUMO plot of NF-3ABA cocrystal with orbitals involved in electronic transitions in isolated (gaseous) phase (i) using wB97X-D/cc-pvTZ method (ii) using B3LYP/cc-pvTZ method.

The features of the HOMO and LUMO for NF and NF-3ABA with energy values can be seen in Figs. S11 (ESI†) and 6. The HOMO-LUMO energy gap reflects the chemical reactivity of NF and NF-3ABA. A small gap implies high chemical reactivity (low stable) and

large gap implies less chemical reactivity (highly stable).⁶⁰ The stability of molecule can also be related to hardness; the lower stability indicates that the molecule is more softer and hence more reactive. This can be confirmed by global reactivity descriptors as well. The calculated HOMO–LUMO gap for NF and NF-3ABA using wB97X-D/cc-pvTZ is -7.606 and -6.935 eV respectively, whereas calculated HOMO–LUMO gap for NF and NF-3ABA using B3LYP/cc-pvTZ is -3.7843 and -3.0558 eV respectively. The energy gap reflects same pattern by both the functionals as shown in Figs. S11 and 6. After the formation of NF-3ABA, the energy gap decreases, this represents higher electronic transitions. So, chemical reactivity of NF-3ABA is higher than NF.

7. Chemical reactivity descriptors

Global reactivity descriptor helps in prediction of electrophilic and nucleophilic reagent, whereas local reactivity descriptors help in the prediction of the site of electrophilic and nucleophilic attack as well as the order of preference.

7.1. Global reactivity descriptors

Electronegativity (χ), chemical potential (μ), global hardness (η), global softness (S) and electrophilicity index (ω) these all are global reactivity descriptors, exceptionally effective in predicting global reactivity trends.

The energies of frontier molecular orbitals (E_{HOMO} , E_{LUMO}), energy band gap ($E_{HOMO} - E_{LUMO}$), χ , μ , η , S and ω for NF, 3ABA, NF-3ABA are listed in Table 2. The chemical hardness (η) and softness (S) of a molecule is a good indication of the chemical stability of the molecule. The molecules with a large energy gap are known as hard molecule whereas molecules having a small energy gap are known as soft molecules. The soft molecules are more polarizable than the hard ones. The η is a direct measure of the electrophilic stability of a molecule, while S provides a measure of its electrophilic reactivity. The computed η for NF, 3ABA, NF-3ABA is in the order of 3ABA > NF > NF-3ABA, and the value of S is in the order of NF-3ABA > NF > 3ABA. Therefore, the ability of soaking up of electrons

for NF is more prominent and tendency to contribute the electrons is more in the case of NF-3ABA. The ω as another useful reactivity descriptor also quantifies the tendency of a molecule to soak up electrons. A molecule with the high value of ω shows the great propensity of attracting electrons from a generic donor molecule. The calculated ω found in the order: NF-3ABA > NF > 3ABA

Table 2 Calculated E_{HOMO} , E_{LUMO} , energy band gap ($E_{\text{H}} - E_{\text{L}}$), chemical potential (μ), electronegativity (χ), global hardness (η), global softness (S) and global electrophilicity index (ω) at 298.15 K for NF, 3ABA and NF-3ABA.

Molecule	E_{H} (eV)	E_{L} (eV)	$E_{\text{H}} - E_{\text{L}}$ (eV)	χ (eV)	μ (eV)	η (eV)	S (eV $^{-1}$)	ω (eV)	ΔN_{max}	ECT
Using B3LYP/cc-pvTZ										
NF	-6.854	-3.070	3.784	4.962	-4.962	1.892	0.264	6.5066	2.6225	
3ABA	-6.012	-1.450	4.561	3.731	-3.731	2.281	0.219	3.0519	1.6359	0.9866
NF-3ABA	-6.063	-3.007	3.056	4.535	-4.535	1.528	0.327	6.7311	2.9683	
Using WB97XD/cc-pvTZ										
NF	-8.71	-1.103	7.606	4.9066	-4.907	3.803	0.131	3.165	1.29	
3ABA	-7.94	0.509	8.449	3.7153	-3.715	4.224	0.118	1.634	0.879	0.4106
NF-3ABA	-7.979	-1.044	6.935	4.5115	-4.511	3.468	0.144	2.935	1.301	

from 3ABA to NF as ECT > 0. Therefore, NF acts as electron acceptor and 3ABA as electron donor. The low value of chemical potential and high value of electrophilicity index for NF favor its electrophilic behavior. In the same way, the high value of chemical potential and low value of electrophilicity index for 3ABA favour its nucleophilic behavior.

7.2. Local reactivity descriptors

Using Hirshfeld atomic charges of neutral, cation and anion state of NF-3ABA, Fukui Function (FF) (f_k^+ , f_k^- , f_k^0), local softnesses (s_k^+ , s_k^- , s_k^0) and local electrophilicity indices (ω_k^+ , ω_k^- , ω_k^0) were calculated. Fukui functions, local softnesses and local electrophilicity indices for selected atomic sites in NF-3ABA have been listed in Table S10 (ESI†). The calculated local electronic descriptors (f_k^+ , s_k^+ , ω_k^+), (f_k^- , s_k^- , ω_k^-), (f_k^+/f_k^-) and (f_k^-/f_k^+) and (f_k^-/f_k^0), (f_k^+/f_k^-) and (f_k^-/f_k^0) ratio values are only capable for providing a clear distinction between more reactive atomic centres. The maximum values of all the three local electrophilic reactivity descriptors (f_k^+ , s_k^+ , ω_k^+) and the highest ratio value of (f_k^+/f_k^-) at N7 indicate that this site has greater chance of attacking the nucleophilic site of the other molecules. The maximum values of all the three local nucleophilic reactivity descriptors (f_k^- , s_k^- , ω_k^-) for O3, O6 and N14 atoms found to be (0.1322, 0.01906, 0.38797), (0.1272, 0.01834, 0.3733) and (0.07236, 0.01043, 0.21235) respectively. The highest ratio value of (f_k^-/f_k^+) at N14 of nitro group indicates that this site is more reactive than O3 and O6 oxygen. Therefore, the nitrogen atom (N14) has greater possibility of attacking the electrophilic site of the other molecules.

The pictorial representation of these electrophilic and nucleophilic atomic sites of NF-3ABA is shown by molecular electrostatic potential surface analysis (ESI†).

8. Molar refractivity (MR)

The MR reflects the dispersivity of the valence electrons, which depends on the mass, charge, and polarizability of the molecule. MR is also related to volume of the molecule and London dispersive force, which act in the ligand-receptors interactions. This is an important property for estimating the biological activity of NF-3ABA. For (MR), the succeeding range is between 40 e.s.u. and 130 e.s.u., with an average value of 97.⁶¹ The value of the MR for NF-3ABA is 55.78 and 55.10 e.s.u using WB97XD/cc-pvTZ and B3LYP/cc-pvTZ level of theory respectively. Here this value of MR is

indicating that NF-3ABA has an obvious capacity to accept electrons (strong electrophile) than NF (API) and 3ABA (coformer).

Electrophilic charge transfer (ECT) is calculated as 0.4106 and 0.9866 using WB97XD and B3LYP functionals respectively for reactant molecules NF and 3ABA, which indicates that charge flows

responsible for the polarizability and reactivity of the NF-3ABA which is an important feature concerning pharmaceutical point of view.

VI. Conclusions

An effective study has been performed on the structural and spectral characteristics of an API, NF, and NF-3ABA cocrystal by experimental spectroscopic methods and quantum chemical calculations. The performance of different methods (experimental and theoretical) has been investigated to elucidate the variation of properties of nitrofurantoin-3-aminobenzoic acid cocrystal and to study the hydrogen bond interactions. Spectral analysis shows that imide N-H, C=O group of hydantoin ring in NF interact with acid C=O, -OH in 3ABA to form NF-3ABA cocrystal. Red shift in the stretching wavenumber is observed in the case NF-3ABA in comparison to NF due to hydrogen bonding functionalities such as NH, OH and C=O causes elongation in the corresponding bond lengths in NF-3ABA. The solid-state NMR spectra provided further evidence of the intermolecular interactions in the NF-3ABA cocrystal. The theoretically constructed IR and Raman spectra of NF-3ABA using WB97XD/cc-pvTZ level of theory shows good correlation with experimentally observed ones. For calculating ^{13}C NMR shifts, the best results for ^{13}C was obtained with WB97XD/cc-pvTZ method with GIAO approaches (mae = 3.29 ppm and 2.60 ppm for NF-3ABA and NF respectively). Therefore, the results suggest that WB97XD is best applied DFT functional to describe the hydrogen bonding interactions in comparison to B3LYP. Topological, geometrical and energetic parameters calculated using QTAIM suggest that the O1...H40 and O27...H23 are moderate in nature as ($\nabla^2 \rho_{\text{BCP}} > 0$, $H_{\text{BCP}} < 0$ with the maximum interaction energy $E_{\text{int}} = 12.34$ kcal/mol. The calculated interaction energy (E_{int}) of NF-3ABA using WB97XD/cc-pvTZ and B3LYP/cc-pvTZ DFT methods are -16.76 and -14.51 kcal/mol respectively. The HOMO-LUMO energy band gap explain the activity of the molecule, concluding that NF-3ABA is more reactive than NF. Global electrophilicity index ($\omega = 6.7311$ eV) shows that NF-3ABA is a stronger electrophile than NF and 3ABA. From the molecular electrostatic potential (MEP) map and reactivity descriptor calculations, the NO₂ group is suitable for electrophilic attack

PAPER

in NF-3ABA. The calculated value of electrophilic charge transfer ECT > 0 indicating that the charge flows from 3ABA to NF during NF-3ABA formation. Thus, NF behaves as electron acceptor and 3ABA as electron donor. Molar refractivity value (55.78 e.s.u.) of NF-3ABA lies in the range set for drug likeness. As a result, cocrystal may be used as an orally active drug. The calculations which we performed in this manuscript have wide scope in the drug discovery. Moreover, reactivity is a primary step for the identification of chemical properties of the drug molecule. Hence, we hope that the studies performed on NF-3ABA cocrystal will be of significant impact in the spectroscopy field as well as pharmaceutical industry.

Acknowledgements

Solid-state NMR spectra for NF, 3ABA and NF-3ABA were obtained at the EPSRC UK National Solid-state NMR Service at Durham. We are thankful to Prof. Alejandro P Ayala, Departamento de Física, Universidade Federal do Ceará, Fortaleza, Brasil for performing FT-Raman of the cocrystal. We thank Mr Nitin Jadhav and Dr Richard Telford for their helpful discussions. A. Shukla thanks financial assistance from the DST (New Delhi) under the DST purse programme. E. Khan and K. Srivastava are thankful for the support from the UGC under BSR meritorious fellowship scheme. P. Tandon acknowledges the financial support provided by the DST, India under the Indo-Brazil project. V. R. Vangala acknowledges the financial support of the Royal Society of Chemistry for mobility grant (2015/17).

Part I. FIGURES

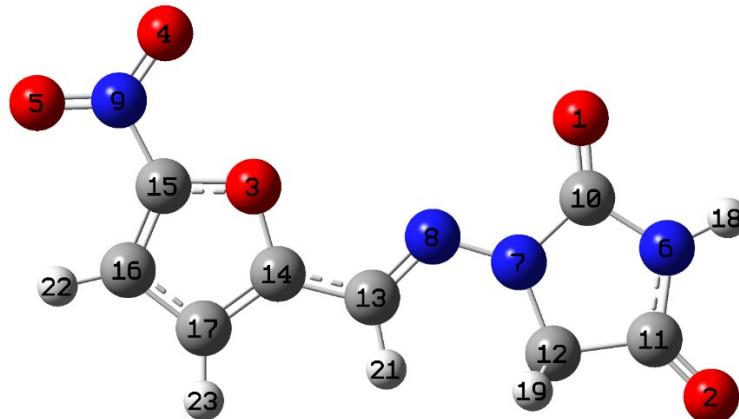

Fig. S1 Optimized structure for NF using wB97X-D/cc-pvTZ method and the atom numbering scheme adopted in this study.

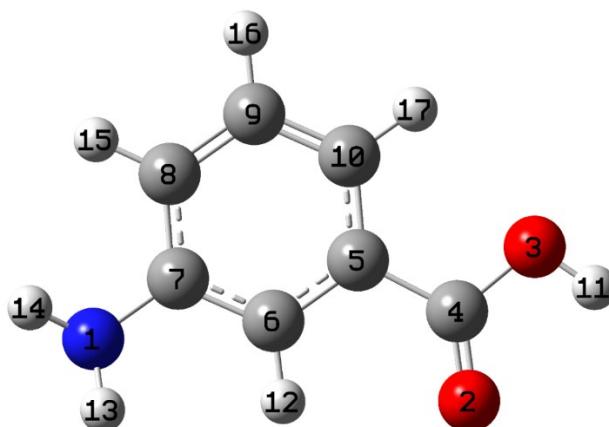

Fig. S2 Optimized structure for 3ABA using wB97X-D/cc-pvTZ method and the atom numbering scheme adopted in this study.

Vibrational assignments

NF-3ABA has hydrogen bonding that is reflected in both calculated IR and Raman spectra. To understand the effect of hydrogen bonding on IR and Raman spectra, we selected NH, OH and C=O stretching modes, as these bonds are involved in hydrogen bonding in the NF-3ABA. Calculated infrared spectra of NF-3ABA, NF and 3ABA which comprise of N-H, C=O and O-H stretching frequencies are shown in Fig. S7 (ESI†). The wavenumbers calculated using B3LYP/cc-pvTZ is given in the parenthesis.

Carbonyl group (C=O) vibrations are characteristic bands in vibrational spectra and for this reason; these types of bands have been subject of extensive studies.^{1,2} The carbonyl compounds give rise to strong bands in the region 1870-1650 cm⁻¹.³ The C16=O stretching mode is observed as medium band at 1827 cm⁻¹ in the IR spectrum and calculated as medium intensity band at 1837 (1808) cm⁻¹. The C12=O stretching mode is observed as medium band at 1788 cm⁻¹ in the IR spectrum and strong band at 1776 cm⁻¹ in the Raman spectrum, however, it is calculated as medium intensity band at 1751 (1722) cm⁻¹, which matches well with the value calculated using wB97X-D/cc-pvTZ. The same mode is calculated at 1798 (1771) cm⁻¹ for NF (API) and observed at 1782 cm⁻¹ in the IR spectrum of NF. The unusual lowering of the carbonyl stretching wavenumber is also contributed to the electron releasing effect of the C=O bond due to intra-molecular charge transfer, as reported earlier⁴ in addition to the intermolecular effect. This shift is clearly shown in the Fig. S7.

The position of N-H stretching band is dependent on the strength of hydrogen bond formed. In the observed FT-IR spectrum of NF-3ABA, the N5-H stretch is observed as a medium peak at 3150 cm⁻¹ in the IR spectrum and at 3151 cm⁻¹ in the Raman spectrum of NF-3ABA, whereas it is calculated as 3153 (3124) cm⁻¹, which matches well with the value calculated using wB97X-D/cc-pvTZ level of theory. The same mode is calculated at 3516 (3503) cm⁻¹ and observed at 3287 cm⁻¹ in the IR spectrum of NF. The N-H of Ring 2 is hydrogen bonded with C=O bond of carboxylic acid attached to the Ring 3 and the lowering of NH stretching wavenumber can be endorsed to the intermolecular N-H···O interaction.⁵ This lowering in the wavenumber from NF to NF-3ABA is clearly shown in the Fig. S7.

The stretching vibration C34=O27 is calculated to be 1693 (1660) cm⁻¹ and corresponds to the peak at 1688 cm⁻¹/ 1686 cm⁻¹ in IR/Raman spectrum, which matches well with the value calculated using wB97X-D/cc-pvTZ level of theory. The same mode is calculated at 1757 (1725) cm⁻¹ and observed at 1751 cm⁻¹/ 1696 cm⁻¹ in the IR/Raman spectrum of 3-ABA. The lowering of wavenumber (as shown in Fig. S7) is due to presence of hydrogen bond in the NF-3ABA. The non-hydrogen bonded (free) hydroxyl group absorbs strongly in the region 3700-3584 cm⁻¹. Whereas the existence of hydrogen bond can lower the O-H stretching frequency to the 3550-3200 cm⁻¹ region with increase in intensity and breadth.^{6,7} The IR spectrum in the high wavenumber region shows a broad band at 3200 cm⁻¹ and at 3216 cm⁻¹ in the Raman spectrum attributed to hydrogen bonded OH stretching vibrations, whereas it is calculated at 3252 (3218) cm⁻¹ in the case of NF-3ABA. The same mode is calculated at 3670 (3626) cm⁻¹ in the case of 3ABA and observed at 3559 cm⁻¹ in the IR spectra. This confirms that the OH group participate in intermolecular hydrogen bonding with a neighbouring molecule. The OH deformation mode appears as medium peak at 1400 cm⁻¹/1399 cm⁻¹ in the IR/Raman spectrum whereas it is calculated at 1405 (1396) cm⁻¹.

Reduced density gradient (RDG) and isosurface analysis

The multi-wavefunction analysis has been performed by reduced density gradient (RDG) plot and isosurface analysis of interactions to confirm the results obtain from the QTAIM analysis and the type of interactions present in the NF-3ABA. For this, initially the cube files were generated for the real spatial functions λ_{2p} (the product of second largest eigen value of Hessian matrix and electron density) and RDG by Multiwfn software. Furthermore, we have plotted a scatter graph with isosurface value of about 0.5 a.u by taking λ_{2p} in x-axis and RDG in y-axis as shown in Fig. S9 (ESI[†]). Each point in the graph corresponds to the critical points in AIM theory. If a horizontal line is drawn to the specified isosurface value (0.5 a.u), then the points crossing the line correspond to the RDG isosurfaces. It is seen from the graph that there are spike shaped collection of points in the region from -0.045 to 0.030 a.u and based on the value of λ_{2p} , the strength of the interactions were distinguished. In the figure shown, the points enclosed in the blue box correspond to hydrogen bonding interactions, the points enclosed in green box represent van der Waals interactions and the points enclosed in red box represent steric effect. Steric effect also has been observed where the ring is formed via hydrogen bonds. The isosurface density map for the non-bonded interactions is shown in Fig. S10 (ESI[†]), which indicates steric effect by red in colour and van der Waals interactions in dark green and hydrogen bond by blue in colour. From isosurface plot, the bond between imide NH, C=O of NF and acid C=O and -OH group in 3ABA is hydrogen bonded and represent by dark blue in colour showing its moderate nature.

Molecular electrostatic potential map of NF-3ABA

The molecular electrostatic potential (MEP) gives a pictorial method to recognize the relative polarity of the molecule. It can be used to analyse the electrophilic and the nucleophilic sites within the molecule where chemical reactions are likely to take place. The electrostatic potential is computed by creating an electrostatic potential grid. The different values of the electrostatic potential at the MEP surface are represented by different colours; red, electron rich; blue, electron deficient; light blue, slightly electron deficient region; yellow, slightly electron rich region; green, neutral; respectively.

The total electron density and electrostatic potential surface (ESP) of the molecules under investigation are constructed by using wB97X-D/cc-pvTZ method. The total electron density mapped with electrostatic potential surface of NF-3ABA is shown in Fig. S12. This orientation visibly show electrophilic region visible as red blob is localized over the NO_2 and carbonyl group attached to the ring R1 and R2 of the molecule respectively. In addition, a less negative area reflected as a yellowish blob is visible mainly over the oxygen atoms of carboxylic group attached to the ring R3 and a more nucleophilic region localised on the NH_2 and CH_2 group and is reflected as a bluish blob.

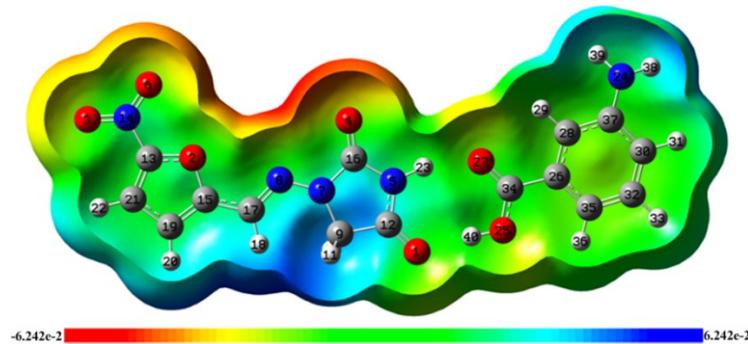

Fig. S12 Molecular electrostatic potential (MEP) formed using wB97X-D/cc-pvTZ method by mapping total density over electrostatic potential in gas phase for NF-3ABA cocrystal.

Table S7 Results of correlation analysis for ^{13}C shifts (in ppm) with GIAO scheme.

Molecule	Functional	b	a	S_0	R^2	mae
NF-3ABA	B3LYP	0.95785±0.02	1.81088±3.25	2.76962	0.99616	4.46
	wB97X-D	0.96124±0.02	1.76111±2.62	2.23697	0.9975	3.87
NF	B3LYP	0.95248±0.04	4.63059±6.24	4.66822	0.99322	3.29
	wB97X-D	0.95091±0.03	5.68234±4.47	3.38138	0.99645	2.60

'a' is the intercept and b is the slope of the correlation line, ' R^2 ' is the square of correlation coefficient, ' S_0 ' is the standard deviation of the points from the correlation line, and 'mae' is the mean absolute error.

^aE(2) means energy of hyper conjugative interaction (stabilization energy), ^bEnergy difference between donor (i) and acceptor (j) NBO orbitals, ^cF(i,j) is the Fock matrix element between i and j NBO orbitals.

Table S10 Selected reactivity descriptors as Fukui functions (f_k^+ , f_k^-), local softnesses (s_k^+ , s_k^-), local electrophilicity indices (ω_k^+ , ω_k^-) for NF – 3-ABA acid using wb97X-D/cc-pvTZ.

Sites	$f_k^+(e)$	$\omega_k^+(ev)$.	$s_k^+(ev^{-1})$	$f_k^-(e)$	$\omega_k^-(ev)$.	$s_k^-(ev^{-1})$	f_k^+/f_k^-	f_k^-/f_k^+
