Porcine reproductive and respiratory syndrome virus (PRRSV) is the causative agent of arguably the most economically important global swine disease. The extensive genetic variation of PRRSV strains is a major obstacle for heterologous protection of current vaccines. Previously, we constructed a panel of chimeric viruses containing only the ectodomain sequences of DNA-shuffled structural genes of different PRRSV strains in the backbone of a commercial vaccine, and found that one chimeric virus had an improved cross-protection efficacy. In this present study, to further enhance the cross-protective efficacy against heterologous strains, we constructed a novel chimeric virus VR2385-S3456 containing the full-length sequences of shuffled structural genes (ORFs 3-6) from 6 heterologous PRRSV strains in the backbone of PRRSV strain VR2385. We showed that the chimeric virus VR2385-S3456 induced a high level of neutralizing antibodies in pigs against two heterologous strains. A subsequent vaccination and challenge study in 48 pigs revealed that the chimeric virus VR2385-S3456 conferred an enhanced cross-protection when challenged with heterologous virus strain NADC20 or a contemporary heterologous strain RFLP 1-7-4. The results suggest that the chimera VR2385-S3456 may be a good PRRSV vaccine candidate for further development to confer heterologous protection.

**Key words:** Porcine reproductive and respiratory syndrome virus (PRRSV); vaccine; DNA shuffling; cross-protection; heterologous strains; RFLP 1-7-4.

## 44 **1. Introduction**

45 Porcine reproductive and respiratory syndrome virus (PRRSV) causes an economically  
46 important global swine disease resulting in more than \$660 million annual economic losses to  
47 the swine industry in the United States alone [1, 2]. As a single-strand positive-sense RNA  
48 virus, PRRSV has an extremely high mutation rate which is approximately  $10^{-2}$ /site/year  
49 [3-6]. Field strains with extensive genetic variations have been frequently emerging since its  
50 initial isolation from pigs in 1989 [3, 7, 8]. These diverse populations of virus strains are  
51 classified into two distinct genotypes, type 1 and type 2, and at least 9 distinct genetic  
52 lineages can be subdivided within type 2 [7, 8]. The current commercially available vaccines  
53 only confer a limited level of cross-protection against heterologous PRRSV strains [9-11].  
54 Therefore, an important objective for PRRSV control is to develop a universal vaccine that  
55 can provide better heterologous protection than the current available vaccines [12, 13].

56 One promising strategy to achieve this objective is to include protective immunogenic  
57 domains from different strains in the vaccine by molecular breeding of multiple heterologous  
58 strains through DNA shuffling. By mimicking natural recombination process *in vivo*, DNA  
59 shuffling can rapidly generate recombinants with desired phenotypes *in vitro* [14]. The DNA  
60 shuffling approach has been successfully used to generate desired phenotypes of viruses such  
61 as Murine leukemia virus strains, Dengue virus, and Venezuelan equine encephalitis virus  
62 [15-17].

63 The PRRSV genome encodes at least eight structural proteins, most of which are important  
64 for protective immunity [18, 19]. The major envelope glycoprotein GP5 has been extensively  
65 studied as a target for PRRSV vaccine development since it contains neutralizing epitopes

66 and contributes to virus entry into cells through heterodimers formed with membrane protein  
67 (M). GP5 has also been showed to be responsible for PRRSV virulence [20-24]. Minor  
68 envelope glycoproteins (GP2, GP3, GP4) also induce neutralizing antibodies and play  
69 important roles in cell entry by interacting with the cellular receptor CD163 [25-28].  
70 Therefore, for the rational design of a broadly cross-protective vaccine, both major and minor  
71 PRRSV envelope proteins should be considered.

72 Previously, we have individually shuffled each of the GP3, GP4, GP5, and M genes in the  
73 backbone of PRRSV virulent strain VR2385 through DNA shuffling [29-31]. We identified  
74 chimeric viruses with improved cross-neutralizing activities against heterologous virus strains  
75 *in vitro*. Furthermore, we demonstrated that, when the ectodomain sequences of these  
76 individually-shuffled structural genes were assembled into the backbone of a commercial  
77 vaccine (Foster<sup>®</sup> PRRS), the resulting chimeria FV-SPDS-VR2 conferred improved  
78 heterologous protection [32].

79 In this present study, we hypothesized that inclusion of the full-length, not just the  
80 ectodomain, sequences of each individually-shuffled structural genes in the backbone of  
81 PRRSV strain VR2385, which is the original backbone used to screen for individual chimeras  
82 with improved cross-neutralizing activities, would further improve the heterologous  
83 protection. Therefore, a novel chimeric virus VR2385-S3456 containing the full-length  
84 sequences of all shuffled structural genes in the backbone of VR2385 strain was generated in  
85 this study, and shown to induce cross-protection in pigs challenged with heterologous strain  
86 NADC20 and a contemporary heterologous strain RFLP 1-7-4.

87

## 88 **2. Materials and methods**

### 89 *2.1. Cells and viruses*

90 BHK-21 cells were cultured in Dulbecco's Minimal Essential Medium (DMEM)  
91 supplemented with 10% fetal bovine serum (FBS). Monkey kidney cell lines MARC-145  
92 were cultured in low glucose-supplemented DMEM with 10% FBS, and maintained in low  
93 glucose DMEM with 2% FBS for virus propagation. A DNA-launched infectious clone of  
94 PRRSV strain VR2385, pIR-VR2385-CA, was constructed previously [33]. PRRSV strain  
95 VR2385 (lineage 5, accession no. JX044140) was originally isolated from a pig experiencing  
96 severe respiratory disease in Iowa [34, 35]. The attenuated PRRSV strain DS722, a derivative  
97 of VR2385 generated by DNA shuffling of the ORF5 gene, was constructed in our lab  
98 previously [30]. The PRRSV strain NADC20 (lineage 9, accession no. JX069953) was  
99 provided by Dr. Kelly Lager of USDA-National Animal Disease Center [8]. A contemporary  
100 PRRSV strain ISU2014016404 (referred to as "RFLP 1-7-4") belonging to lineage 1 with a  
101 pattern 1-7-4 based on restriction fragment length polymorphism (RFLP) pattern of the ORF5  
102 gene was provided by Dr. Jianqiang Zhang of the Iowa State University [36].

### 103 *2.2. Construction and rescue of chimeric virus*

104 A nucleotide acid sequence fragment S3456 was designed and commercially synthesized  
105 (Integrated DNA Technologies, Coralville, Iowa). The S3456 fragment contains the  
106 full-length sequences of the shuffled ORF3 gene derived from chimera GP3TS22 [29],  
107 shuffled ORF4 gene derived from chimera GP4TS14 [31], shuffled ORF5 gene derived from  
108 chimera DS722 [30], and shuffled ORF6 (M) gene derived from chimera MTS57 [31]. The  
109 overlapping sequences between ORF3 and ORF4 were derived from chimera GP4TS14. The

110 inclusion of the shuffled ORF5 gene from chimera DS722 ensured that the resulting virus is  
111 attenuated, as the DS722 chimera with the shuffled ORF5 gene is attenuated in pigs [30]. By  
112 using the *BsrG* I and *Xba* I restriction enzyme sites engineered into the synthesized fragment  
113 S3456, the full-length sequences of the shuffled ORFs 3-6 were successfully introduced into  
114 the genomic backbone of a DNA-launched PRRSV infectious clone pIR-VR2385-CA, to  
115 create the final chimera designated VR2385-S3456 (**Fig. 1A**).

116 To rescue the chimeric virus VR2385-S3456, fresh BHK-21 cells seeded in a 6-well plate  
117 at approximately 60–80% confluency were transfected with 2 µg of the respective plasmid  
118 DNA per well using the Lipofectamine LTX and Plus Reagent kit (Invitrogen) according to  
119 the manufacturer's instructions. After 48 h incubation at 37°C with 5% CO<sub>2</sub>, cell culture  
120 supernatants were harvested and designated as passage 0 (P0) virus.

### 121 2.3. Indirect immunofluorescence assay (IFA)

122 IFA with an anti-PRRSV antibody (SDOW17) was used to verify PRRSV infection in cells  
123 as described previously [28].

### 124 2.4. Virus growth kinetics and plaque morphology assay

125 To characterize the growth kinetics and properties of the rescued chimeric virus  
126 VR2385-S3456 *in vitro*, a multiple-step growth curve and plaque morphology assays were  
127 conducted in MARC-145 cells as described previously [28].

### 128 2.5. Experimental design for a cross-protection vaccine efficacy study in pigs

129 This study was approved by Virginia Tech Institutional Animal Care and Use Committee  
130 (approval number 16-127). A total of 48 PRRSV-negative piglets [all](#) at 3 weeks of age were  
131 randomly divided into 6 groups of 8 piglets per group [regardless of the body weights](#). Piglets

132 in each group were vaccinated intramuscularly with the novel chimera VR2385-S3456, an  
133 attenuated chimera DS722 containing only shuffled ORF5 [30], or PBS (**Table 1**). Serum  
134 samples were collected from each pig prior to vaccination and weekly thereafter. At 49 days  
135 post-vaccination (dpv), the pigs were challenged with one of two heterologous PRRSV  
136 strains, NADC20 or RFLP 1-7-4 which share 92.9% and 88.2% nucleotide sequence identity  
137 in the ORF5 gene with the VR2385-S3456, respectively. At 14 days post-challenge (dpc), all  
138 pigs were euthanized and necropsied. Lung tissue samples were collected for gross pathology  
139 and histopathology evaluation and quantification of PRRSV RNA load.

#### 140 *2.6. Serum virus neutralization (SVN) assay*

141 The neutralizing antibody (NA) titers against heterologous strains NADC20 and RFLP  
142 1-7-4 were determined by a SVN assay [29]. Briefly, two-fold diluted serum samples  
143 collected at 49 dpv from each pig were mixed with an equal volume of respective test virus at  
144 an infectious titer of  $2 \times 10^3$  TCID<sub>50</sub>/ml and incubated at 37°C for 1 h. The mixture was then  
145 dispensed onto MARC-145 cells in 96-well plates (100 µl/well) and incubated for 1 h at  
146 37°C. After washing with PBS once, the cells were maintained in DMEM (2% FBS) for 20 h.  
147 The cells were fixed and stained for IFA to detect evidence of virus infection. The NA titers  
148 were expressed as the highest dilution that showed at least 90% reduction in the number of  
149 fluorescent foci compared to negative control serum. Three independent tests were performed  
150 for each serum sample.

#### 151 *2.7. Gross pathology and histopathology evaluation of lung tissues*

152 At necropsy, lungs were evaluated for visible gross lesions as described previously [35],  
153 and subsequently five sections of lung tissues were collected, fixed in formalin and processed

154 for histopathology evaluation. The evaluation was conducted by a board-certified veterinary  
155 pathologist who was blinded to the treatment status. For the histopathology evaluation, the  
156 microscopic lung lesions were scored based on the presence and severity of interstitial  
157 pneumonia ranging from 0 to 4 (0, no microscopic lesions; 1, mild interstitial pneumonia; 2,  
158 moderate multifocal interstitial pneumonia; 3, moderate diffuse interstitial pneumonia; 4,  
159 severe interstitial pneumonia).

#### 160 *2.8. Quantitation of viral RNA loads in sera and lung tissues*

161 Serum viral RNAs were extracted from serum samples at 49 dpv, 7 and 14 dpc using ZR  
162 Viral RNA kit (ZYMO RESEARCH, USA) following the manufacturer's protocol. Total  
163 RNAs from the lung tissue were extracted using TRI Reagent (MRC) following the  
164 manufacturer's protocol. The quantitation of PRRSV RNA copy number was conducted by  
165 RT-qPCR as described previously [30, 32].

#### 166 *2.9. Statistical analyses*

167 The data were analyzed using GraphPad Prism (version 6.0). The viral titers were  
168 analyzed by the Student's t test (unpaired), and the other data were analyzed using one-way  
169 ANOVA followed by Tukey's multiple comparison test.

170

### 171 **3. Results**

#### 172 *3.1. Successful rescue of chimeric virus VR2385-S3456 containing the full-length sequences* 173 *of shuffled ORFs 3-6 genes of multiple heterologous strains*

174 Previously, we have successfully generated single envelope gene-shuffled chimeric  
175 PRRSV viruses (GP3TS22, GP4TS14, DS722 and MTS57), in the genomic backbone of a

176 virulent PRRSV strain VR2385, as well as a multiple genes-shuffled chimeric virus  
177 (FV-SPDS-VR2) in the backbone of commercial vaccine Foster<sup>®</sup> PRRS [29-32]. In an  
178 attempt to further improve the efficacy of cross-protection, in this present study we included  
179 the full-length sequences, not just the ectodomain sequences, of all shuffled structural genes  
180 in the genomic backbone of PRRSV strain VR2385. The rationale is that additional  
181 cross-protective epitopes reside in regions other than the ectodomains. Also, the use of  
182 wild-type PRRSV VR2385 (instead of a MLV) would also enhance humoral and  
183 cell-mediated immune responses.

184 The DNA fragment S3456 representing the full-length sequences of shuffled ORFs3-6  
185 derived from multiple chimeras with respective individually-shuffled gene was commercially  
186 synthesized (**Fig. 1A**). The S3456 was cloned into the backbone of a DNA-launched  
187 infectious clone pIR-VR2385-CA to produce a novel chimera VR2385-S3456. The  
188 authenticity of the chimeric clone VR2385-S3456 was verified by DNA sequencing.

189 Following transfection of BHK-21 cells with the full-length chimeric clone VR2385-S3456,  
190 supernatant was harvested two days post-transfection (P0 virus) and used to inoculate fresh  
191 MARC-145 cells. At four days post-inoculation, cytopathic effects (CPEs) were observed in  
192 inoculated cells. IFA using PRRSV N-specific monoclonal antibody confirmed that the CPEs  
193 were PRRSV-specific, thus indicative of the production of viable progeny viruses (**Fig. 1B**).  
194 To further confirm that the rescued virus indeed originated from the clone, the ORFs3-6  
195 genes were amplified from the P3 viruses by RT-PCR and sequenced. Sequence data (not  
196 shown) confirmed that the ORFs3-6 of the rescued virus were identical to that of the original  
197 chimeric clone. Therefore, the results demonstrated the successful rescue of a viable novel

198 chimeric virus VR2385-S3456 containing the full-length sequences of the shuffled ORFs 3-6  
199 genes.

200 *3.2. Chimeric virus VR2385-S3456 had a reduced growth ability phenotype in MARC-145*  
201 *cells*

202 To evaluate the growth kinetics of the rescued VR2385-S3456, MARC-145 cells were  
203 infected with the P3 virus of the VR2385-S3456 or VR2385 at an MOI of 0.1. The chimeric  
204 virus VR2385-S3456 had an overall reduced growth ability when compared to VR2385 (**Fig.**  
205 **1C**). Specifically, compared to parental virus VR2385, the chimera VR2385-S3456 had  
206 significantly lower virus titers between 48 to 96 h post-inoculation (hpi). The peak virus titer  
207 of the parental virus VR2385 was approximately  $3.0 \times 10^7$  TCID<sub>50</sub>/ml, whereas the peak titer  
208 of the chimera VR2385-S3456 was about  $3.0 \times 10^5$  TCID<sub>50</sub>/ml, 100 times lower than the  
209 parental virus. Compared to the parental virus, the chimeric virus formed smaller and turbid  
210 plaques (**Fig. 1D**) in MARC-145 cells indicating a reduced rate of growth and spread to  
211 adjacent cells. This is consistent with the observations on growth kinetics. Collectively, the  
212 results showed that the chimeric virus VR2385-S3456 containing the full-length sequences of  
213 the shuffled ORFs3-6 genes are viable and have a reduced growth ability in MARC-145 cells.

214 *3.3. Chimeric virus VR2385-S3456 induced higher cross-neutralizing antibodies against*  
215 *heterologous virus strains NADC20 and RFLP 1-7-4*

216 To evaluate the efficacy of heterologous protection of the chimeric virus VR2385-S3456,  
217 we conducted a vaccination/challenge study in pigs. Since the PRRSV strain VR2385 is a  
218 virulent strain [35], a derivative of VR2385, chimera DS722, which contains a shuffled GP5  
219 gene and is attenuated, was used as the control [30]. After vaccination, the anti-PRRSV

220 antibodies in each pig were monitored using the IDEXX HerdChek X3 ELISA kit. The data  
221 showed that all vaccinated pigs seroconverted at 14 dpv, while the negative control group  
222 pigs remained seronegative until after challenge (**Table 2**).

223 To investigate whether the chimeric virus induces cross-neutralizing antibodies against  
224 heterologous strains NADC20 and RFLP 1-7-4, an SVN assay was performed using serum  
225 samples collected at 49 dpv. When tested against the heterologous virus strain NADC20 (**Fig.**  
226 **2A**), both DS722- and VR2385-S3456-vaccinated pigs produced a higher level of NA titers,  
227 and the VR2385-S3456 group (mean value 5.5) was significantly higher than the DS722  
228 group (mean value 4.1). When tested against the heterologous virus strain RFLP 1-7-4 (**Fig.**  
229 **2B**), both vaccinated groups produced NAs, and the VR2385-S3456 group (mean value 2.4)  
230 was significantly higher than the DS722 group (mean value 1.7). Overall, the NA titers  
231 against the RFLP 1-7-4 strain were not as high as those against the NADC20 strain.  
232 Nevertheless, the results suggested that the chimeric virus VR2385-S3456 induced  
233 cross-neutralizing antibodies against heterologous PRRSV strains NADC20 and RFLP 1-7-4.

234 *3.4. Chimeric virus VR2385-S3456-vaccinated pigs had more average daily weight gain*  
235 *(ADWG) and less microscopic lung lesions after challenge*

236 After challenge, three pigs in the PBS/NADC20 group, and two in the PBS/RFLP 1-7-4  
237 group developed mild respiratory symptoms (**Table 2**). Prior to challenge, there was no  
238 statistically significant difference in ADWG between any vaccinated groups and PBS control  
239 group (**Fig. 3A**). After challenge with heterologous strain NADC20, both DS722- and  
240 VR2385-S3456-vaccinated pigs had more ADWG than the PBS control group (**Fig. 3B**).  
241 After challenge with heterologous strain RFLP 1-7-4, the VR2385-S3456-vaccinated pigs

242 had more ADWG than DS722-vaccinated and PBS control pigs (**Fig. 3B**).

243 For microscopic lung lesions, the VR2385-S3456-vaccinated group had lower lesion  
244 scores than the DS722-vaccinated group when challenged with NADC20 (**Fig. 3C**). The  
245 VR2385-S3456-vaccinated group had numerically lower microscopic lung lesion scores,  
246 although not statistically significant, than the DS722-vaccinated group when challenged with  
247 RFLP 1-7-4 (**Fig. 3D**). The gross lung lesion scores were not statistically different between  
248 groups (data not shown).

249 *3.5. Chimeric virus VR2385-S3456-vaccinated pigs had reduced viral RNA loads in sera and*  
250 *lung tissues after challenge*

251 Viral RNA loads in serum and lung are routinely used as a parameter for measuring virus  
252 replication level for PRRSV studies [30, 37, 38]. Only one pig in the  
253 VR2385-S3456/NADC20 group had a low but detectable PRRSV viremia ( $1.6 \times 10^3$  copies/ml)  
254 at 49 dpv (**Table 2**) indicating that most pigs had cleared the residual vaccine virus at the  
255 time of challenge. When challenged with NADC20, both DS722- and  
256 VR2385-S3456-vaccinated groups had significantly reduced levels of serum viral RNA  
257 copies at 7, 14 dpc compared to the non-vaccinated group (**Fig. 4A, B**). Compared to the  
258 DS722-vaccinated group, the VR2385-S3456-vaccinated group had a numerically lower viral  
259 RNA copies, although the difference was not significant. 62.5% (5/8) pigs in the  
260 DS722-vaccinated group, and 85.7% (6/7) pigs in the VR2385-S3456-vaccinated group were  
261 negative for viral RNAs in sera at 14 dpc. Also, the viral RNA loads in the lung tissues of  
262 both DS722- and VR2385-S3456-vaccinated groups were significantly decreased when  
263 compared to the non-vaccinated control group (**Fig. 4C**). The VR2385-S3456-vaccinated pigs

264 showed numerically lower viral RNA loads, although not significantly different, in lung  
265 tissues than the DS722-vaccinated group.

266 For pigs challenged with RFLP 1-7-4, both DS722- and VR2385-S3456-vaccinated groups  
267 had significantly decreased levels of viral RNA loads in sera (7, 14 dpc) and lung tissues (14  
268 dpc) compared to the non-vaccinated control group (**Fig. 4D-4F**). Similarly, the  
269 VR2385-S3456-vaccinated group had a numerically lower viral RNA copy number than that  
270 of DS722-vaccinated group, although the difference was not statistically significant. 62.5%  
271 (5/8) of pigs in the DS722-vaccinated and 71.4% (5/7) of VR2385-S3456-vaccinated groups  
272 were negative for viral RNA loads in lung tissues at 14 dpc.

### 273 *3.6. Chimeric virus VR2385-S3456 was genetically stable in vitro and in vivo*

274 To investigate the genetic stability of the chimeric virus VR2385-S3456, the virus was  
275 serially passaged to P8 in MARC-145 cells. The ORFs3-6 sequences of the P8 virus showed  
276 a 99.9% nucleotide sequence identity to the P3 virus. The chimeric virus recovered from the  
277 serum samples of infected pigs at 14 dpv had 99.8% nucleotide sequence identity to that of  
278 the original virus.

279

## 280 **4. Discussion**

281 The extensive genetic and antigenic diversity of field PRRSV strains worldwide makes the  
282 current commercial vaccines, which are all based on a single virus strain, less effective in  
283 protection against diverse field strains [9, 11, 39]. Enhancing cross-protection is critically  
284 important but a major challenge for the development of the next generation PRRSV vaccines  
285 [10, 13, 40, 41]. To overcome this challenge, one strategy is to expand the antigenic coverage

286 of PRRSV vaccines [12]. Molecular breeding through DNA shuffling has been shown to be a  
287 very promising approach to expand the antigenic coverage [15, 42, 43].

288 Previously, we successfully generated a chimeric virus FV-SPDS-VR2 containing only the  
289 ectodomains of the shuffled structural genes (ORFs3-6) in the genomic backbone of a  
290 commercial vaccine [32]. In this present study, we constructed a novel and improved  
291 chimeric virus VR2385-S3456. Compared to FV-SPDS-VR2, the novel chimeric virus  
292 VR2385-S3456 from this study has two key improvements: (1) It contains the full-length, not  
293 just the ectodomains, sequences of each shuffled structural genes; (2) The full-length  
294 sequences of the shuffled structural genes from multiple strains were cloned into the genomic  
295 backbone of PRRSV strain VR2385, which was originally used to screen those single  
296 gene-shuffled chimeras with significantly higher cross-neutralizing activities [29-31].

297 The vaccine efficacy of the novel chimera VR2385-S3456 was tested in a  
298 vaccination/challenge pig model. The results showed that the novel chimera VR2385-S3456  
299 conferred an enhanced cross-protection against heterologous virus strains NADC20 and  
300 RFLP 1-7-4. In the parental virus control group, we used the chimera DS722 virus which  
301 contains the shuffled GP5 gene. The DS722 has previously been shown to induce similar  
302 immune protection compared to the wild-type virulent VR2385 but is attenuated in pigs [30].  
303 After vaccination, both DS722- and VR2385-S3456-vaccinated pigs had similar ADWG to  
304 the PBS control pigs, suggesting a good safety of both DS722 and VR2385-S3456. Although  
305 cell-mediated immunity is also important for protection against PRRSV, neutralizing  
306 antibodies is an important parameter to assess protection in pigs against PRRSV infection [32,  
307 37, 40]. At 49 dpv, VR2385-S3456-vaccinated pigs produced higher NA titers against

308 heterologous strains NADC20 and RFLP 1-7-4. Based on the ORF5 sequences, the RFLP  
309 1-7-4 strain used in this study as well as the strain MN184B both belong to genetic lineage 1  
310 [8]. Protection against lineage 1 strains is important, as the lineage 1 virus is currently highly  
311 prevalent [38, 41]. Unfortunately all the chimeric viruses from previously studies induced  
312 only very low NA titers ( $<1$ ) against the lineage 1 MN184B strain [32]. In this present study,  
313 we found that most of VR2385-S3456-vaccinated pigs (11/14) and some of  
314 DS722-vaccinated pigs (6/16) elicited relatively higher NA titers ( $>2$ ) against the lineage 1  
315 RFLP 1-7-4. It remains to be determined if the aforementioned two improvements of the  
316 novel chimera VR2385-S3456 are responsible for the observed higher NA titers against a  
317 lineage 1 virus strain.

318 When challenged with the heterologous strain NADC20, the VR2385-S3456-vaccinated  
319 pigs had an improved ADWG, lower microscopic lung lesion scores, reduced viral RNA  
320 loads in sera and lung tissues than the DS722-vaccinated or PBS control pigs. Importantly,  
321 most of VR2385-S3456-vaccinated pigs had cleared the viruses at necropsy. The data  
322 indicated that VR2385-S3456 conferred cross-protection against the heterologous strain  
323 NADC20.

324 When challenged with a contemporary lineage 1 virus RFLP 1-7-4 which is currently  
325 circulating in North America, similar results were observed, suggesting a good protection  
326 against the heterologous strain RFLP 1-7-4. We noticed that the chimera DS722 also  
327 provided a partial protection against the two heterologous strains, indicating that the shuffled  
328 GP5 gene, which is the same for chimera DS722 and chimera VR2385-S3456, may have  
329 played a role in cross-protection as well.

330 In summary, in this study we successfully generated a novel chimeric virus VR2385-S3456  
331 which contains the full-length sequences of each shuffled structural genes of ORFs 3-6 in the  
332 genomic backbone of a PRRSV strain VR2385. The rescued chimeric virus had a reduced  
333 replication ability *in vitro*, induced relatively higher NA titers, and conferred an enhanced  
334 cross-protection in pigs against two heterologous virus strains. Therefore, the novel chimeric  
335 virus VR2385-S3456 is a good candidate for further development as a PRRSV vaccine.

336

### 337 **Acknowledgments**

338 We thank Dr. Kelly Lager from the USDA National Animal Disease Center and Dr Jianqiang  
339 Zhang from Iowa State University for providing the challenge virus strains. We also thank  
340 Qian M. Cao and Dr. Harini Sooryanarain for their assistance during necropsy. We thank the  
341 Virginia Tech TRACSS staff for animal cares. This project was supported by internal funds  
342 from Virginia Tech.

**FIG. 1. Construction and virological characteristics of a novel chimeric virus VR2385-S3456.** (A). Schematic diagrams of the genomic organization of the genomic backbone VR2385 virus and the novel chimeric virus VR2385-S3456. The genes derived from the backbone VR2385 virus are depicted with open rectangles. Each pattern in the genes of the shuffled ORFs3-6 represents a single shuffled gene derived from one of the single gene-shuffled chimeric viruses (GP3TS22, GP4TS14, DS722, MTS57) respectively, which are shown at the bottom. (B). Two days post-transfection of BHK-21 cells with the VR2385 backbone as well as the novel chimeric virus clone, the P0 virus supernatants were harvested and used to inoculate fresh MARC-145 cells. Cells were fixed at 48 h post-inoculation, and immunostained by IFA with anti-PRRSV N monoclonal antibody (SDOW17). The parental virus VR2385 and the rescued novel chimeric virus VR2385-S3456 were passaged in MARC-145 cells to P3. (C). The P3 virus was used to infect fresh MARC-145 cells at an MOI of 0.1. The culture supernatants were collected at indicated time points. Infectious titers were determined and calculated using the Reed-Muench method. Three independent experiments were carried out for each virus. (D). Plaque morphology. The P3 viruses were used to infect MARC-145 cells, and then overlaid with medium containing 2% FBS and 1% low-melting-point agarose. Four days later, the cells were visualized by crystal violet staining.

510  
511

**FIG. 2. Neutralizing antibody (NA) titers induced by the novel chimeric virus VR2385-S3456 in pigs against heterologous PRRSV strains NADC20 and RFLP 1-7-4.**

512 At 49 dpv, the sera from vaccinated and control pigs were collected to determine the NA  
513 titers using MARC-145 cells by serum virus neutralization (SVN) assay. The NA titers were  
514 expressed as the highest dilution ( $2^n$ ) that showed a 90% or above reduction in the number of  
515 fluorescent foci compared to that of negative control serum. **(A)**. NA against a heterologous  
516 strain NADC20. **(B)**. NA against a contemporary heterologous strain RFLP 1-7-4. Each plot  
517 represents the mean titer of three separate tests, and the error bars indicate standard errors. *P*  
518 values were shown (\*\*  $P < 0.01$ , \*\*\*\*  $P < 0.0001$ ).

519

520 **FIG. 3. Average daily weight gain and microscopic lung lesions of vaccinated pigs.**

521 Average daily weight gain (ADWG) before **(A)** and after **(B)** virus challenge in vaccinated  
522 pigs. The pigs were weighed at the time of vaccination (0 dpv), challenge (49 dpv) and  
523 necropsy (14 dpc), respectively. For the evaluation of histological lung lesions, the lung  
524 tissues were fixed in formalin and scored for histological lesions by a board-certified  
525 veterinary pathologist **(C, D)**. Each plot represents the value of one pig, and the error bars  
526 indicate standard errors. Significant difference is indicated with asterisks (\*  $P < 0.05$ ).

527

528 **FIG. 4. Viral RNA loads in sera and lung tissues after challenge with heterologous virus**

529 **strains NADC20 and RFLP 1-7-4.** PRRSV RNA copy numbers in sera at 7 dpc **(A, D)**  
530 and 14 dpc **(B, E)**, and in lung tissues at 14 dpc **(C, F)** were determined by RT-qPCR. The  
531 detection limit is 3 log<sub>10</sub> copies per ml (serum) or gram (lung tissue). Samples below the  
532 detection limit were considered as negative, and calculated as 2 log<sub>10</sub> copies for statistical  
533 analysis. Each plot represents the mean viral RNA copy number of triplicate testing results of

534 one pig, and the error bars indicate standard errors. *P* values were shown (\*  $P < 0.05$ , \*\*  
535  $P < 0.01$ , \*\*\*  $P < 0.001$ , \*\*\*\*  $P < 0.0001$ ).
