

Metabolism of goniotalamin in animal and microbial system

ABSTRACT

Of the twenty microorganisms screened for metabolism of goniotalamin only *Streptomyces aureofaciens* ATCC 10762 and *Nocardia* species NRRL 5646 produced two metabolites, 3,4-dihydrogoniotalamin and 3,4,7,8 tetrahydrogoniotalamin. The identity of the isolated metabolites were established using TLC, HPLC, MS, IR, and ¹H- and ¹³C-NMR spectroscopy. In addition, the substrate had been transformed into two unknown metabolites by *Aspergillus niger* ATCC 11394 and *Septomyxa affinis* ATCC 6737 in low yield. Three of the metabolites were also detected and identified in the urine and blood samples of the goniotalamin-treated Sprague-Dawley rats. The obtained results are in agreement with and support the principle of microbial models of mammalian metabolism.
